THE MEDICAL ASPECTS OF MODERN LIFE INSURANCE.

BY FREDERICK L. HOFFMAN,

NEWARK, N. J.

STATISTICIAN, THE PRUDENTIAL INSURANCE COMPANY.

THE medical considerations which underlie the assumption of risk in life insurance practice are deserving of much more scientific and extended consideration than has heretofore been the case. A review of the various textbooks on medical examinations published during the last fifty years proves conclusively that insurance medicine has not shared, to anything like the desired degree, in the enormous advances made by general medicine and operative surgery during this period. For reasons which do not require to be considered at this time, it has always been difficult to maintain a periodical in the United States exclusively devoted to insurance medicine in all its branches, although several such publications have been quite successful in Germany and elsewhere. For many years the general medical periodical press of the United States has given attention to questions and problems of life insurance medicine and practically the whole field has been covered by occasional contributions accessible through large medical libraries and the convenient medium of the Index Medicus and the Catalogue of the Surgeon General's library. The extent to which this has been the case is made evident by the fact that the title "Life Insurance," not to mention some of the sub-titles of the subject, takes up nearly fourteen closely printed columns in Vol. IX of the second series of the Index Catalogue of the Surgeon General's library, including hundreds of valuable articles of a highly practical nature, aside from numerous theoretical discussions. The subject is divided into examinations for life insurance and the methods for proceeding in such examinations, examinations for testing the urine, examinations for life insurance in relation to disease, habits, heredity, sex, age, duties and responsibilities of life insurance examiners, instructions to life insurance examiners, jurisprudence of life insurance, statistics of life insurance, life insurance in relation to race and climate, life tables, etc.

The large aspects of life insurance medicine include, however, much more than questions and problems, methods and results, of medical examination. Differentiating precisely between the functions of the examiner and the medical director, it is obvious that the latter requires to consider the many aspects of life insurance from a much broader and more comprehensive point of view than the former. All that is summed up in a company's mortality experience involves medical considerations of a most delicate and involved nature, comprehending practically the entire field of general medicine and physical diagnosis. At least all of the larger companies are giving an increasing amount of attention to the qualified analysis of their mortality experience by causes of death, duration of insurance, etc., with the necessary distinction of locality, age, sex, race, occupation, family history, physique, etc. Concerning any one of these questions a vast amount of most useful information is contained in the periodical medical press which, if properly utilized, must needs prove of material aid in the successful administration of the medical department of a life insurance company. Opinions will probably always differ as to what constitutes the ideal risk and there will perhaps never come a time when standardized or uniform principles of selection will govern in the acceptance or rejection of life insurance applicants. The practice of the different companies must necessarily vary according to their size, their length of experience, their territory of operation, their class of applicants and methods of solicitation, so that any given individual risk not suitable for one company may be properly accepted by another. The medical policy of every company must be largely governed by the facts of its own experience rather than by the results of the combined experience of many companies, the statistical and medical interpretation of which is often a most difficult task for ordinary office requirements. In determining its medical policy it is, therefore, of the utmost importance that the medical department of each company should be as fully informed as possible concerning all of the numerous factors which have reference to its own experience and the required information must chiefly be obtained through the medical periodical press.

It would carry me too far to illustrate the foregoing suggestions to the extent as I have had occasion to do in my address on "The Mutual Relations of Life Insurance and the Medical Press."* I can here only refer to a few recent articles which will emphasize the point of view that the medical periodicals are the most valuable source of information concerning practical suggestions for a further improvement in the science of life insurance medicine. In the Journal of the *American Medical Association* for February 23, 1907, appeared an interesting article by S. J. Meltzer, M.D., of New York City, on "The Factors of Safety in Animal Structure and Animal Economy." The article throws much light upon some of the most obscure problems in risk selection, where a well-established impairment may be sufficiently compensated for by obviously and equally well established physiological advantages.

Another illustration is an address by Dr. George M. Gould, read at the 51st Annual Meeting of the American Medical Association in 1900, on " A System of Personal Biologic Examinations and the Condition of Adequate Medical and Scientific Con-

*Proceedings of the American Medical Editors' Association, 1910.

duct of Life." In the discussion by Gould are included considerations of heredity, development, adolescence, anthropometric examination, the physiological record, including the testing and tabulation of all the significant reactions and functions, etc., foreshadowing the work of the Eugenic Institute at Cold Springs Harbor, New York.

There can be no more serious error than to assume that all of the fundamental principles of longevity have been ascertained, when, rather to the contrary, it is a question of reasonable doubt whether any of the factors which determine the length of human life have been precisely established by modern methods of scientific research. In the MEDICAL RECORD for December 24, 1910, is an interesting discussion of the probable duration of human life, by Dr. A. H. Stewart, of Lawton, Oklahoma, which reopens the debatable question as to accuracy and trustworthiness in the accounts of extreme longevity, so ably and impartially discussed by T. E. Young in his treatise on Centenarians, published in 1899.

Young also was one of the first to raise the question of probable error in the mortality curves as used for life insurance purposes at the age period of 20 to 29, holding that, according to the experience of the Society of Friends, the death rate is higher at ages 20 to 24 than during the succeeding interval from 25 to 29.

As bearing upon this question, an interesting but brief discussion appeared in the *Journal of the American Medical Association* in 1910, on "Change of Life in Man," by De Fleury, who reported 201 cases representing a form of neurasthenia in men approaching 50, in which the nervous and mental symptoms had been proceeded by signs of sluggish nutrition, auto-intoxication and lower vitality.

In this manner, every branch and subject of insurance medicine could be illustrated by citations from the medical periodical press, often contributing most valuable hints and suggestions applicable to everyday practice, not to be derived from the textbooks on examinations for life insurance, nor could it be expected that books of this character would contain the required information, since, as previously stated, the distinction is obvious between the field of the medical examiner and the medical director. To the former the field of opportunity is largely unrealized, and students of general medicine might well give more attention to more rigid requirements of intelligent and conclusive examinations, not only for life insurance purposes, but also for the recruiting service of the Army and Navy, the Pension Office, large industrial establishments, transportation lines, etc. The adoption of a system of medical examination of school children has materially enlarged the field in which such knowledge could be utilized to pecuniary advantage in present-day recognition of the truth that not only is prevention of disease better than cure, but that such prevention is a social duty, incumbent alike upon the individual and the State.

Suprarenal Tumors and Precocity.—Glynn and Dun state that the evidence at their disposal suggests that the internal secretion of true malignant hypernephromata in children tends to increase the male primary and secondary sexual characters at the expense of the female; as is seen in the occurrence of beards in several of the female children, the hypertrophy of the clitoris, and the earlier true sexual maturity of the male children.—*Liverpool Medico-Chirurgical Journal.*

ON THE MECHANISM OF THE PRESYSTOLIC MURMUR.*

By T. STUART HART, A.M., M.D.,

NEW YORK.

ASSOCIATE IN MEDICINE, COLUMBIA UNIVERSITY.

In 1843 Fauvel[1] described the presystolic murmur and advanced the view that it was due to abnormal blood currents caused by obstruction at the mitral orifice during the systole of the auricle. A few years later Gairdner[2] supported this view with much force and originality. Since Gairdner's time clinicians have been practically agreed that this short rough crescendo murmur terminating with the first sound of the heart and usually audible over a very limited area near the apex, is indicative of mitral stenosis, but the forces which are active in its causation have been the subject of extensive controversy.

Ormerod[3] claimed that the musculature of the auricle was not powerful enough to produce a murmur of the character of the presystolic and Barclay[4] put forward the view that the murmur was systolic in time and was caused by a portion of the ventricular contraction which preceded the first sound. These views have been further amplified by Dickinson,[5] Brockbank,[6] and others.

However, up to the present time it would seem as if the arguments of the supporters of the view that the auricular systole is an important element in the production of the presystolic murmur have been generally accepted.[7] For example, Sansom[8] in the closing paragraphs of a full discussion of the presystolic murmur, asserts "it manifests a heightened intensity at its close due to the contributory expulsive force of the auricle." And Gibson[9] says "that the explanation of Fauvel and Gairdner is correct cannot in my opinion be doubted for a moment."

In his recent study of the heart by graphic methods the rôle of the auricular systole in the production of the presystolic murmur has been emphasized by Mackenzie,[10] who has made use of the disappearance of the presystolic murmur as an argument for the absence of an auricular contraction at the normal period in the cardiac cycle. It seems evident, therefore, that Mackenzie holds the view that the presystolic mitral murmur is due to auricular systole.

Some time ago our attention was attracted by the fact that in certain cases with evident mitral stenosis with well marked presystolic thrill and presystolic murmur at the apex, the jugular pulse was of the ventricular type, the tracings conformed in detail to the type designated by Mackenzie as the "nodal rythm."

In some of these the mitral valve only was affected, in others there was either a certainty or a suspicion of an aortic insufficiency complicating the picture of pure mitral disease.

The following are instances of mitral involvement only:

CASE I.—P. W., salesman, thirty-seven years of age, was admitted to the Presbyterian Hospital on March 26, 1909. He had been accustomed to consume large quantities of beer and whisky and had suffered from one or two slight attacks of rheuma-

*Presented to the Society of Internal Medicine, February 15, 1911.

From the service of Professor James at the Presbyterian Hospital, New York.

The presystolic murmur associated with aortic insufficiency, the "Flint murmur," is not considered in the present discussion.

tism (?). He denied syphilis. For four years he had suffered from dyspnea on exertion, for the six months preceding his admission he had a cough with expectoration sometimes streaked with blood. He complained of dyspnea, edema of the legs, pain in the shoulders, cough and constipation.

On examination he appeared quite cyanotic and apathetic. His pulse was one of complete irregularity, rate about 128; some of the apex beats could not be felt at the wrist. The apex of the heart was in the sixth space 17 cm. to the left of the midsternal line, dullness extending 2.5 cm. outside of this point, there was abnormal dullness in the second and third left spaces where a systolic pulsation could be felt, and there was some dullness to the right of the sternum. There was heard a loud first sound at the apex, with *a short, rough, rumbling murmur preceding it;* also a blowing systolic murmur transmitted to the axilla. The second pulmonic sound was accentuated. The lungs showed signs of congestion at the bases. The liver was pulsating and tender. There was edema of the legs and arms.

rheumatism, but was conscious of no after effects. One year ago after much running upstairs in his position as office boy he suddenly became short of breath. Since that time he has been unable to work. He has had some precordial pain, a cough with brown expectoration, and occasional vertigo. His dyspnoea and precordial pain had been much worse for the two weeks preceding his admission to the hospital.

His physical examination showed a moderate degree of cyanosis. Respiration, 40. The lungs showed a few crepitant râles over the left upper lobe. The apex of the heart was in the fifth space 10 cm. to the left of the midsternal line, its action was very irregular, thrusting and forcible. At the apex there was a marked thrill and *a loud crescendo rumble preceding the first sound* which was followed by a short systolic whiff. There was a soft diastolic murmur heard in the third left space. The sounds at the base were both loud, but the pulmonic was the more intense and at times was reduplicated. The radial pulse was small, rapid, and irregular in

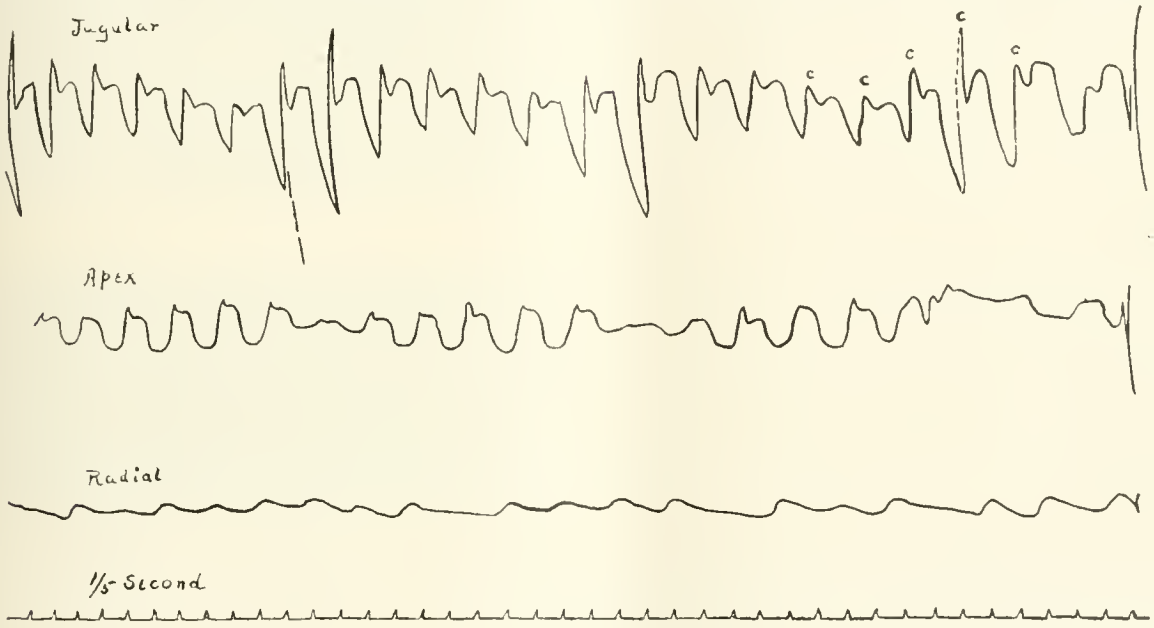

Fig. 1.—Jugular apex and radial tracings in Case I. Note absence of *a* wave and ventricular form of venous pulse; complete irregularity.

The tracing Fig. 1 was taken on March 27, when his condition had not materially changed; at this time the presystolic murmur was present. It is to be noted that the tracing shows a jugular pulse of ventricular form with no evidence of an *a* wave and that the radial pulse is characterized by complete irregularity.

Case II.—J. K., an office boy, twenty years old, was admitted to the hospital on May 4, 1910. He denied syphilis and the use of alcohol. When eight years of age he had an attack of acute articular

force and time. During his whole stay in the hospital, until July 15, the thrill and murmur preceding the first sound were never absent.

Figure 2 is a tracing taken on May 11, when the physical signs were as above described.

The tracing shows a jugular pulse of the ventricular form and the brachial shows complete irregularity.

In the earlier period of these observations we were led to suspect that the absence of the *a* wave in its normal position in the venous pulse was due

Fig. 2.—Jugular and brachial tracings in Case II. Note absence of *a* wave and ventricular form of the venous pulse; complete irregularity.

to technical defect, but repeated attempts in obtaining tracings* confirmed our impression that the venous pulse was of the ventricular type. Therefore in spite of the generally accepted theory of Fauvel and Gairdner that the abrupt increase in the intensity of the murmur preceding the first sound in mitral stenosis is due to auricular contraction, and in spite of the evidence of Mackenzie of the presence of an auricular form of venous pulse when a presystolic murmur is present we were led to suspect that there might be cases of mitral stenosis (without aortic insufficiency) in which the presystolic murmur was associated with a ventricular form of venous pulse.

Recently Professor Evans called our attention to a case of mitral stenosis with a presystolic murmur, complete irregularity and the ventricular form of venous pulse which had been under his observation at the City Hospital for some months. He was good enough to allow the patient to be transferred to the Presbyterian Hospital for polygraph and electrocardiographic records and it is through his courtesy that we are now reporting this case.

Case III.—M. G., hack driver, thirty-six years of age, a native of Russia. Family history good. He denied syphilis. He has been accustomed to use tobacco and beer in moderation. Ten years ago he had a severe attack of rheumatism; a year after this he had some cardiac palpitation, but no dyspnoea or other circulatory disturbances. Five years ago when apparently in good health he suddenly "vomited some bright red frothy blood." He lost consciousness and was taken to Bellevue Hospital, where he remained for seven weeks. He was then well until two years ago, when he had a similar attack and was in the hospital six weeks. After this he noticed shortness of breath during the cold weather, but not in summer. At this time he was able to walk only on the level. Sometimes after exertion he had a sharp pain which "ran through his heart" and made him stop his work. Recently his ankles have been swelling and he has had some epistaxis. He was admitted to the service of Professor Evans at the City Hospital, who made a diagnosis of mitral stenosis with decompensation. On December 20, 1910, he came to the Presbyterian Hospital, where records were taken with the polygraph and with Einthoven's string galvanometer.

At that time the heart showed enlargement to both left and right, the action was very rapid and tumultous, the apex beat was thumping and varied greatly in force and time. There was a loud first sound *preceded by a thrill and a short, sharp crescendo murmur* and followed by a musical systolic murmur. In the longer diastolic pauses a low pitched soft murmur could occasionally be heard in the third left space near the sternum. The second pulmonic sound was accentuated. The radial pulse was small and completely irregular, the veins of the neck were pulsating.

Figure 3 shows a tracing of the brachial and jugular pulses; the jugular is clearly of the ventricular form.

Figure 4 is his electrocardiographic record taken at the same time. Leads one and two are reproduced together with a short control which shows that the galvanometer was practically free from vibration. The electrocardiograms show complete irregularity, the *P* wave characteristic of auricular contraction is absent, but the small uneven waves clearly indicate that the auricle is in a state of fibrillation.

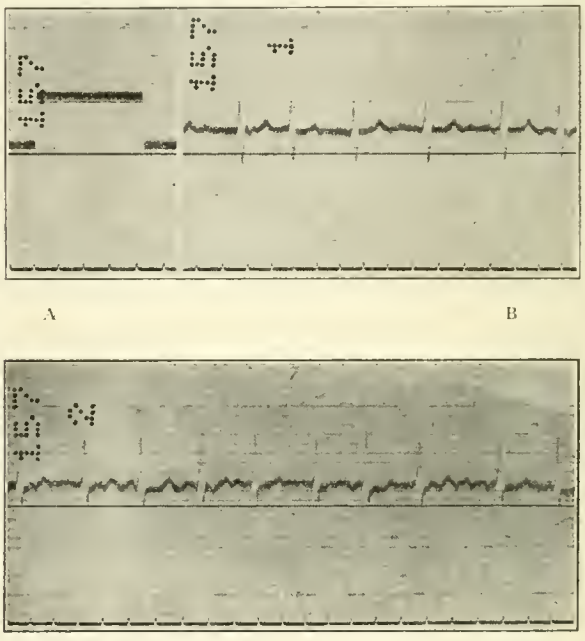

Fig. 4.—Electrocardiogram in Case III, taken December 20, 1910. A, control; B, Lead I; C, Lead II; time of each, 1/5 second. Note the absence of P wave and oscillation characteristic of auricular fibrillation.

On the same day he returned to the City Hospital and was put on large doses of digitalis. On January 8 he was again transferred to the Presbyterian Hospital and remained there until his discharge, greatly improved, on January 23.

The electrocardiogram taken in association with the venous tracing on January 9 shows the heart action after it had been quieted by rest and digitalis. Fibrillation, complete irregularity and the ventricular form of venous pulse are all evident.

*The polygraph records were taken either with a Ludwig kymograph (Fig. 1) or with the sphygmotonograph of Uskoff (both instruments manufactured by Zimmermann). The brachial tracings were obtained by means of the cuff attachment of the Uskoff instrument.

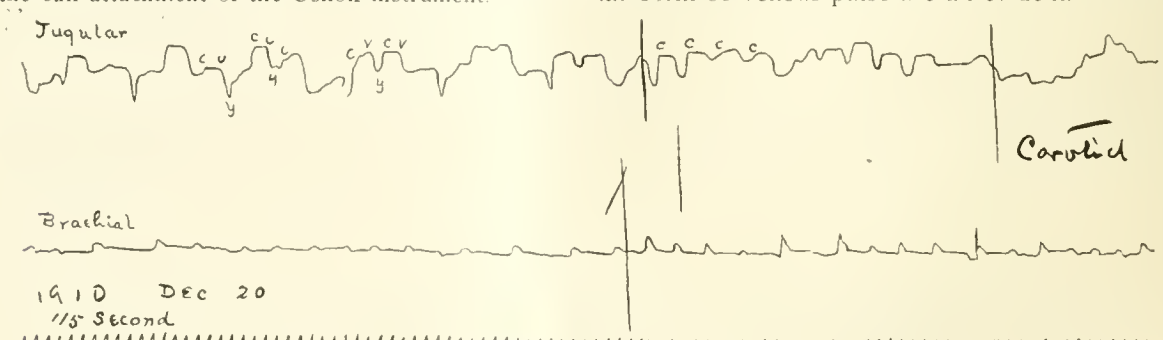

Fig. 3.—Jugular and brachial tracings in Case III. Note absence of *a* wave and the ventricular form of the venous pulse; complete irregularity.

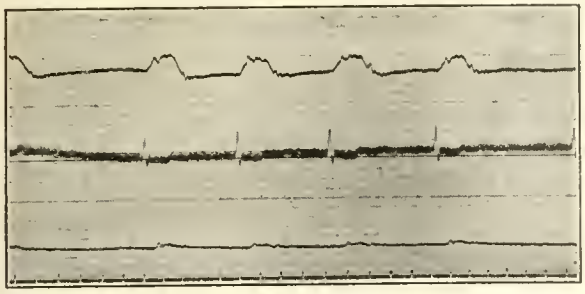
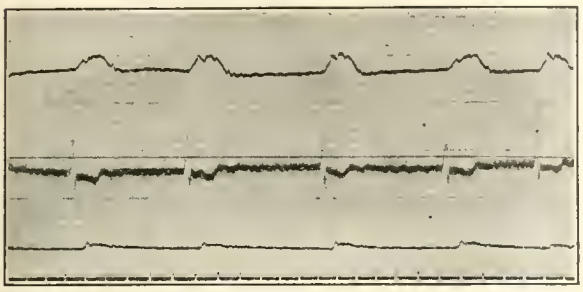
At this time the apex beat was in the fifth space 11.5 cm. to the left of the midsternal line, dullness extended 15 cm. to the left in the fifth space, 8 cm. to the left in the third space and 4 cm. to the right in the fourth space. At the apex the first sound was loud and sharp and preceded by a thrill, at the base



Lead I, time, 1/5 second.



Lead II, time, 1/5 second.

Fig. 5.—Electrocardiogram in Case III, taken January 9, 1911, after rest and digitalis; the upper line is the jugular tracing, the lower line the radial pulse. Note absence of the P wave, complete irregularity, fibrillation.

the pulmonic sound was accentuated and occasionally there was reduplication. The murmurs were as described in the note of December 20, but were more easily differentiated during the slow action of the heart. They are shown graphically in the diagram Fig. 6.

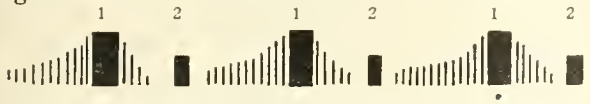


Fig. 6.—Diagrammatic representation of murmurs in Case III.

The thrill and murmur preceding the first sound could be greatly increased by mild muscular movements. The radial pulse was small and irregular; there was no capillary pulsation.

about two weeks, of shortness of breath with palpitation and considerable difficulty in climbing stairs. Three months ago an attack came on and was so severe that he could not walk far, even on the level. Since then he has been unable to work, he has had dyspnea, orthopnea, a sense of fullness after eating, and occasional nausea. There has been no swelling of the legs, but some puffiness of the face in the morning. One month ago he was jaundiced and had pain and tenderness in the region of the liver. The jaundice has now nearly disappeared.

The physical examination on January 12 showed a well nourished man slightly jaundiced, not anemic or cyanotic. There was marked pulsation of the veins of the neck. The apex of the heart was localized and palpable in the fifth space 9.5 cm. to the left of the midsternal line, dullness extended 0.5 cm. further to the left. Rate, 106, irregular in force and time. At the apex there was a short, sharp, snappy first sound *preceded by a thrill and a short, harsh crescendo murmur* (these could be markedly increased by slight muscular exertion). There was a blowing systolic murmur heard at the apex and a systolic murmur harsh and prolonged heard at the costal margin and along the left edge of the

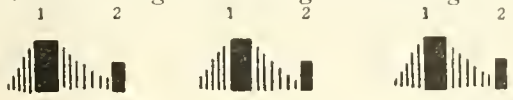

Fig. 7.—Diagrammatic representation of murmurs in Case IV.

sternum. In Fig. 7 the murmurs are represented diagrammatically. The second pulmonic sound was accentuated. The radial pulse was small and corresponded to the apex beat in force and rythm. The liver extended from the fourth space in the right midclavicular line to 3.5 cm. below the costal margin; it was pulsating and tender. There was no edema of the extremities.

Figures 8 and 9 exhibit the records of Case 4 on admission January 12.

The venous pulse is of the ventricular form, the evidence of the absence of gross auricular contractions is complete, there is an absence of the *a* wave in the venous tracing and of the *P* wave in the electrocardiogram, which shows small oscillations due to auricular fibrillation; there is complete irregularity.

The patient was put in bed and given digitalis. During his stay in the hospital numerous records were taken of which Fig. 10 was taken on January

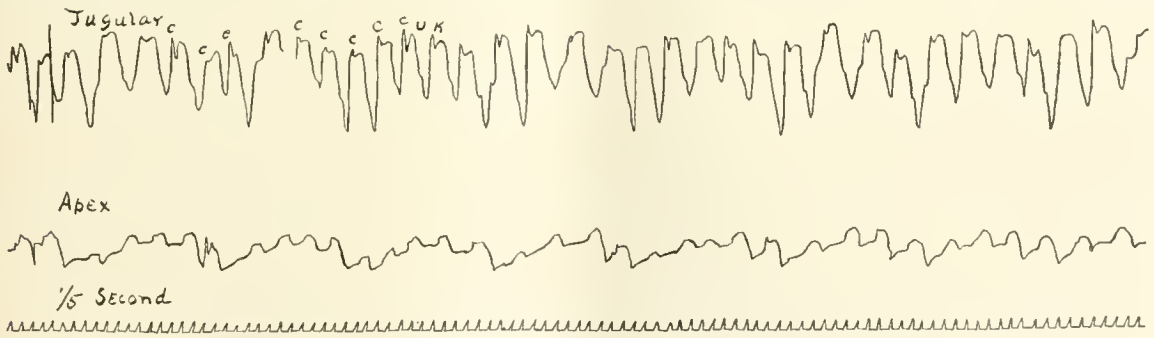

Fig. 8.—Jugular and apex tracings on admission in Case IV. Note ventricular form of the venous pulse; complete irregularity.

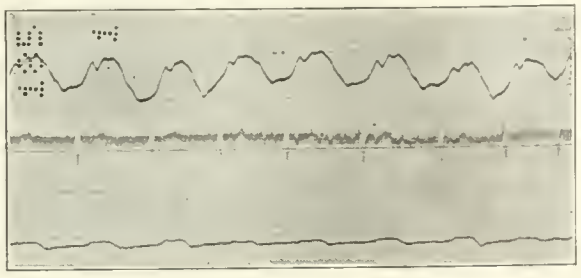
Case IV.—A. F., a barber, thirty years old, born in Poland, was first seen at the Vanderbilt Clinic on January 11, 1911, and was admitted on the next day to the Presbyterian Hospital. His family history was good. He denied syphilis and rheumatism and the use of alcohol and tobacco. About once a year for the past ten years he has had attacks, lasting

22. All these records showed auricular fibrillation, complete irregularity and the ventricular form of venous pulse.

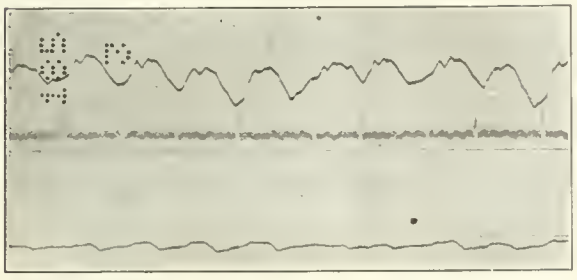
We have presented here in detail four cases with well marked clinical signs of mitral stenosis, and we have records of a number of others which could be included in this group. The physical signs in all

of these cases have been verified by Professor James and other competent observers.

In two of these cases the presence of a diastolic murmur might suggest the presence of an associated aortic insufficiency, but since there was an appre-



Lead I.



Lead II.

FIG. 9.—Case IV on admission, January 12, 1911. Records from above downward; jugular pulse of ventricular form, absence of *a* wave; electrocardiogram, absence of *P* wave and fibrillation; brachial pulse, complete irregularity.

ciable interval between the second sound and the beginning of the murmurs in question, since the enlargement of the left ventricle was very moderate, since the arterial pulse was exceedingly small and showed no collapsing quality, and since there were no capillary phenomena or other signs characteristic of aortic leakage we feel reasonably assured that we are dealing in all of these cases with mitral lesions only.

At no time during the observation of these cases was there an absence of the so-called presystolic thrill and presystolic murmur. Many graphic records of these cases were secured; they invariably exhibited complete irregularity, the ventricular form of venous pulse and an entire absence of evidence of gross auricular contraction. From Cases 1 and 2 no electrocardiograms were obtained, but from the character of the polygraph tracings we have no doubt that had these been secured they would have shown auricular fibrillation.

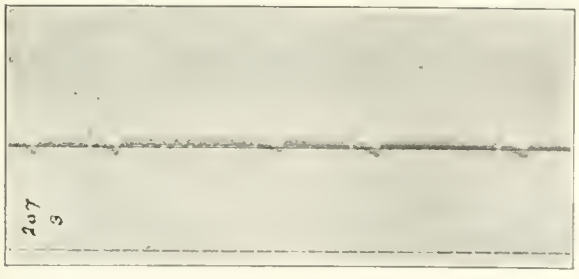


FIG. 10.—Electrocardiogram in Case IV, taken January 22, 1911, after rest and digitalis; fibrillation. Lead III, time, 1/5 second.

The conclusion is obvious that, *in certain cases at least, the short crescendo murmur preceding the first sound in mitral stenosis is not due to auricular activity.*

While we are not prepared to assert that this murmur is never due to auricular activity, our findings are certainly exceptions to the theory of Fauvel and Gairdner and as such tend to materially weaken it.

The arguments in favor of the view that the murmur in question is due to ventricular activity may be found in the papers of Dickinson[5] and Brockbank.[6] While there are some facts which this theory does not (to our way of thinking) satisfactorily meet, our observations favor it in so far as they deny the necessity of auricular activity for the production of this murmur.

To Professor James, who has allowed me the freedom of his wards, has placed the means of this study at my disposal and has encouraged and aided its prosecution by personal aid and suggestion, and to Dr. H. B. Williams, who has assisted me in taking the records, I wish to express my obligation and thanks.

THE RADICAL FRONTAL SINUS OPERATIONS.

TYPE OF OPERATION BEST ADAPTED TO THE CURE OF SINUS DISEASE WITH THE LEAST EXTERNAL DEFORMITY.

BY JOHN E. MACKENTY, M.D.,

AND

GERHARD H. COCKS, M.D.,

NEW YORK.

RECENTLY, both in this country and abroad, Killian's radical frontal sinus operation has become deservedly popular. This is due partly to the recognition always afforded any operative procedure advocated by this eminent teacher, and partly to the excellent results Killian has achieved. The main objection to the method, especially in America, is the inevitable facial deformity resulting from the removal of the anterior bony wall of the sinus.

It has been our experience, from a series of cases operated by a somewhat different method, that a cure of the underlying disease may be attained with much less—or, indeed, practically no—external deformity. For this reason we are prompted to publish our results and give a brief description of the operation we have employed.

It need hardly be said that all cases should be carefully selected before they are subjected to any radical external operation. Unless prompt interference is indicated, the usual intranasal methods for the establishment of free drainage by the natural passages should first be given a fair trial for several months.

Excluding the osteoplastic flap operations which have gained little recognition in this country, the

radical operations on the frontal sinus may be divided into three groups:

(*a*) Operations where the anterior wall of the sinus is removed: (1) Method of Nebinger-Praun. (2) Method of Luc-Ogston. (3) Method of Kuhnt.

(*b*) Operation with removal of floor of sinus: (1) Method of Jansen.

(*c*) Operations with removal of both anterior wall and floor: (1) Method of Riedel. (2) Method of Killian.

Of the methods directed at the obliteration of the frontal sinus by the removal of its anterior wall, that of Kuhnt is perhaps the best known. The anterior bony wall is completely removed; the mucous membrane lining the sinus is thoroughly curetted away, but the nasofrontal duct is undisturbed. The external wound is left open, the cavity packed with gauze, and the wound made to heal from the bottom. Needless to say, the resulting deformity is great, and the ethmoidal cells—which are practically always involved in chronic frontal sinus suppuration—Kuhnt leaves undisturbed.

Jansen was the first to attack the frontal sinus by way of the floor, and his method has much to recommend it. He makes a curved skin incision below and parallel to the eyebrow, and continues it down on the side of the nose through the periosteum to the bone. After separating the periosteum from the roof of the orbit, Jansen removes the floor of the sinus and opens the ethmoid cells. The skin incision is closed and drainage into the nose established. In his published description of his operation, Jansen makes no mention of care in the dislodgment of the pulley of the superior oblique muscle for the purpose of avoiding post-operative diplopia, and he does not resect a window in the anterior wall in cases of high sinuses.

Killian's operation is performed as follows: A curved skin incision is made through the eyebrow from its temporal end toward the median line of the head and down on the side of the nose, to the base of the nasal bone. The periosteal incisions are two in number. The upper is made parallel to the supraorbital margin and 5 mm. above it, and extends from the temporal line of the skin incision as far as the nasal bones. The second periosteal incision begins just internal to the superior oblique pulley, passes inward, and then downward and outward, following the direction of the incision of the skin at the inner side of the eye. The periosteum is separated from the anterior wall of the sinus, with the exception of that covering the superciliary ridge. The periosteum is elevated from the inner portion of the floor of the sinus and from the inner wall of the orbit. Killian then removes the entire anterior wall of the sinus except a narrow bridge of bone at the orbital arch. He also removes the inner part of the sinus floor and the nasal portion of the superior maxilla. He completely exenterates the ethmoid labyrinth. His successful results are due largely to the broad free opening which he makes into the nose. The external wound is closed.

The chief disadvantage in Killian's operation, as mentioned above, is the cosmetic deformity which results, especially when dealing with high and deep sinuses, like those of the first patient reported in this series. In such a case the skin sinks into the cavity above the orbital arch and an unsightly depression occurs. Mainly for this reason—to avoid bad cosmetic results—we determined to try the operation described by Dr. A. Knapp in the *Journal of the American Medical Association*, July 28, 1908, and have found the method so satisfactory that we determined to report some of the cases. The operation, in brief, is as follows:

After the insertion of a post-nasal plug, a semilunar incision is made from the outer angle of the orbit through the unshaved eyebrow, and down on the side of the nose to the level of the floor of the orbit. This incision is through the periosteum to the bone. The periosteum is then separated from the anterior wall of the sinus, and from the roof and inner wall of the orbit. The pulley of the superior oblique is separated from its bony attachment and pushed aside with the periosteum of the orbit. The bulb is held aside with a blunt retractor. The lacrymal sac is elevated from the lacrymal groove, care being taken not to injure the duct. The entire floor of the frontal sinus is removed, as well as the nasal process of the superior maxillary bone, the lacrymal, and, if necessary, a portion of the nasal bone. The entire ethmoidal labyrinth is taken away, including the plate of bone forming the inner wall of the orbit. If indicated, the anterior wall of the sphenoid is removed. Thus we get a large and free opening into the nose.

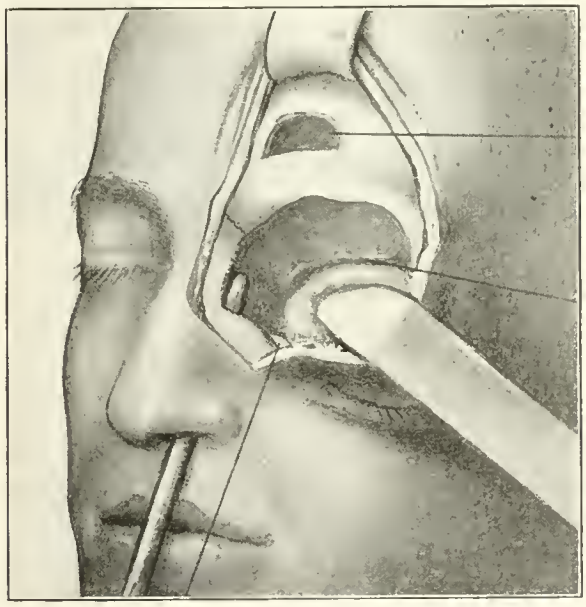

Fig. 1.—Radical operation on frontal sinus and ethmoid; A, instrument passed through nostril to show the wide opening into the nose. B, lacrymal duct. C, edge of floor of the sinus which has been removed. D, window in the anterior wall.

In small sinuses the removal of the floor usually suffices, but when dealing with high sinuses, like those of Case I. of our series, it is generally necessary to make a window in the anterior wall, in order to inspect and curette all parts of the cavity. In any event, a wide bridge of bone, at least as wide as the breadth of the index finger, should be kept at the supraorbital margin, to preserve the normal contour. The entire mucosa lining the frontal sinus is carefully curetted away, and all septa are broken down. The middle turbinate, unless previously removed, is resected at the time of the frontal sinus operation. The external wound is closed by sutures. At least one buried stitch should be placed in the periosteum at the inner angle of the eye, to hold the superior oblique pulley in its proper position. All the skin stitches but one at the inner corner of the eye should be removed in twenty-four hours to avoid stitch scars. A cigarette drain from the sinus into the nose is allowed to remain until the following day. No external drainage is necessary.

This operation differs from Killian's in: (1) The manner of incising the periosteum; (2) The treatment of the anterior wall; (3) The method of handling the superior oblique pulley; (4) The total removal of the floor of the frontal sinus.

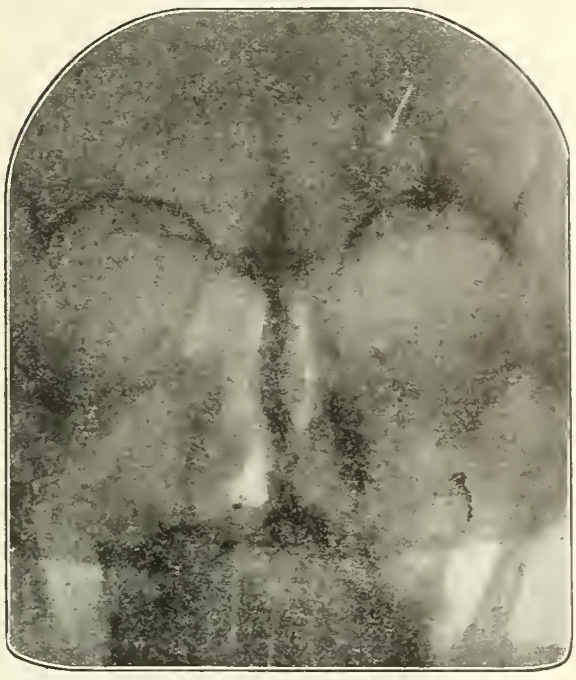

Fig. 2.—Case I—Photograph shows very high frontal sinuses. Arrow points to dark spot in left frontal due to thickening of mucosa. The left ethmoidal and maxillary cavities are darker than the opposite side, and are diseased.

The following are some of our more interesting cases. All these patients were operated in Dr. W. F. Chappell's service at the Manhattan Eye, Ear, and Throat Hospital:

Case I.—C. J., a robust man of 39 years, came to the clinic in December, 1909, with a history of bilateral mucopurulent nasal discharge and headache since childhood. During the past three years he has had repeated intranasal operations for the cure of his nasal trouble in several of the large European cities. His pain has always been over the frontal sinus, with one exception, when he had a bad attack of pain in the occipital region, relieved by intranasal opening of the sphenoid. His last operation was performed eleven months ago in Hamburg. Since then he has been free from pain over the right frontal, but his left-sided trouble has continued. When first seen, a little over a year ago, he sought relief from periodic attacks of dull supraorbital pain, left side. These attacks usually lasted about two weeks. Then there was a free discharge of muco-pus, followed by relief. He was having one of these attacks when he came under observation, and stated that the supraorbital pain began every morning about 9 A. M. and lasted until 3 P. M. He was very drowsy and forgetful, and slept most of the time.

A radiograph, taken in the anteroposterior direction, shows a dark spot in the left sinus, indicated by the arrow (see Fig. 2). This was thought to be due to diseased and thickened mucosa. The same photograph shows that the left antrum is also diseased. Fig. 3, which is the lateral view of the same patient, demonstrates the great distance between the anterior and posterior walls of the vertical portion of the sinus.

Examination of the nose showed that both middle turbinates had been removed, and the ethmoids and sphenoids of both sides opened. Operation was decided upon, and the method of operating described above was carried out. Owing to the height of the sinus, which is well shown in the *x*-ray print, it was necessary to make a window in the anterior wall. The mucosa lining the frontal sinus was thickened, diseased, and polypoidal. The same condition was present in the ethmoid cells, which were completely exenterated.

Following the operation the patient had diplopia while looking at objects in the upper part of the visual field, due to involvement of the superior rectus muscle. This disappeared in two weeks. Otherwise the patient made an uneventful recovery, and is now completely relieved of his pain. His photograph, taken fourteen months after operation, shows the excellent cosmetic result obtained. The scar is no longer noticeable.

Case II.—Mrs. Mack. Came to the clinic seeking relief from left-sided nasal obstruction and purulent discharge. About five years ago was operated upon for the same condition in another institution, with temporary relief. At that time the left middle turbinate was removed. On December 9, 1910, a few polypi were removed by one of the men in the clinic. That same night the patient experienced severe pain in the left eyeball, accompanied by edema of upper and lower eyelids and pronounced exophthalmos. The temperature rose to 104° F. and the edema extended over the lateral aspect of the face as far back as the auricle. The following day, forty-eight hours after the polyp operation, the floor of the frontal sinus was removed and the ethmoids exenterated.

The findings were rather unusual. There was a

Fig. 3.—Case I. Lateral view. Shows great distance between anterior and posterior walls of vertical portion of frontal sinuses.

defect in the region of the ethmoid cells, which were filled with pus. By this path the pus had found its way into the orbital fat, which contained two small abscesses. The frontal sinus itself contained pus under pressure and was filled with polypi. The

sinus was only about one inch high. It was therefore unnecessary to resect a window in the anterior wall. The patient is relieved of both pain and nasal discharge, although a sinus at the upper angle of the orbit has persisted, due to a small piece of

Fig. 4.—Case I. Taken about one year after operation on the left frontal sinus.

dead bone. Consequently, another operation for the removal of the necrotic bone will be necessary.

Case III.—H. H., a middle-aged man, has suffered from periodic attacks of pain over the region of the left frontal sinus for the past fifteen years—at first, every two to four months; recently, every two weeks. The pain lasted one to two days.

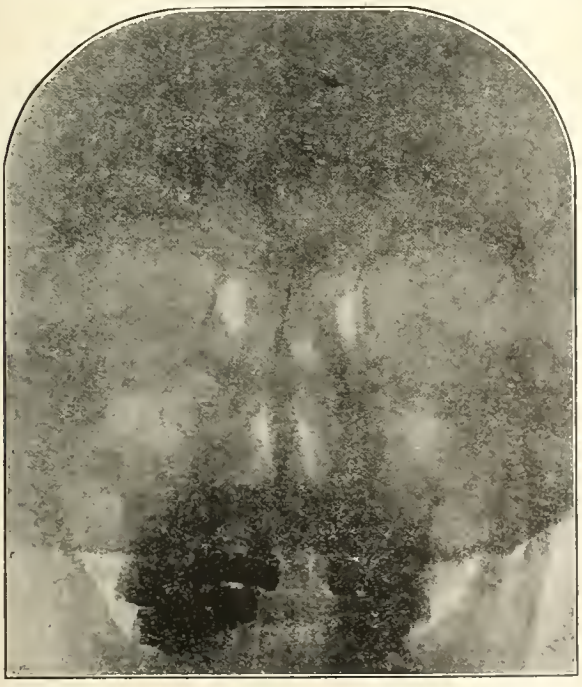

Fig. 5.—Case III. Showing dark shadow in floor of left frontal and in ethmoid region. The left antrum shows enormous thickening of its lining mucosa.

There has never been a purulent discharge, merely a few drops of watery material running out of the nose during the attacks. The last attack was accompanied by a slight rise of temperature. An intranasal operation on the middle turbinate and ethmoids a few years ago, in another institution, failed to give relief. Washings from the left maxillary antrum demonstrated clumps of mucopus. The *x*-ray shows a dark shadow over the left frontal and ethmoidal regions, with enormous

Fig. 6.—Case III. Taken about eight weeks after operation.

thickening of the mucosa lining the left maxillary antrum.

Operation December 21, 1910. Floor of sinus removed, ethmoids and sphenoid opened through inferior meatus, a large hole being made in the nasal wall. The mucosa lining the frontal sinus, especially about the duct, was thickened and inflamed. A small amount of mucopus was present in this region. The ethmoids and sphenoid were filled with degenerated mucous membrane, polypoidal in character. Recovery was uneventful except for secondary infection of skin and deeper structures, necessitating external drainage for a short time. This patient is now completely free from his attacks of pain. The nose is dry. His photograph, taken two months after operation, is here shown.

Case IV.—Jacob S. Chronic purulent pansinusitis. History: Bilateral purulent nasal discharge since January, 1910. Came under observation in September, 1910. Both antra opened through nose and ethmoids operated intranasally. Headache and discharge persisted in spite of these measures, and a radical operation was advised. After three months' observation and treatment, the floor of the right frontal sinus was removed by the external route and the ethmoids and sphenoid opened. The frontal sinus was filled with thick yellow pus and polypi. There was a defect in the bony septum between the two sinuses, through which pus oozed from the left sinus into the cavity of the opposite side. This defect was enlarged by removing the bony septum; thus the left frontal was drained into the right nostril. The cosmetic result is excellent, and the patient's right-sided headache is cured. As he has had some pain over the left sinus, since operation, it will undoubtedly be necessary to do a complete operation on his left frontal and ethmoid before he is entirely cured.

Case V.—Sam H., 32 years old. Pain and left-sided mucopurulent nasal discharge for nine years. Pain is bilateral in supraorbital regions and occiput.

The patient had intranasal operations in the region of the middle turbinate in 1906 and again in 1908. He suffered from epileptic seizures, which came on at the time of the attacks of frontal sinus pain. He was referred by Dr. Joseph Collins, who noted that the epileptic attacks were diminished in number by the nasal operations.

A radical operation was advised, and in November, 1910, the floor of the frontal sinus was removed and the ethmoids opened. The mucosa in the floor of the frontal sinus was thickened and inflamed, and it was apparently this condition which caused the periodic attacks of pain due to the temporary closure of the excretory duct of the sinus. The ethmoids were filled with polypoidal mucous membrane. The cosmetic result is excellent. It is somewhat early to judge of the effect of the operation on the number and severity of the epileptic seizures at the present writing.

Case VI.—E. P., lady's maid; age 28. Well nourished but anemic. Bilateral nasal discharge, yellow and thick; began at the age of fifteen. From that age until she came under observation in the clinic

Fig. 7.—Case VI. Taken over two years after operation on right frontal sinus.

she underwent repeated operations for nasal polypi. One year prior to the present history she began to have bilateral pain over the frontal and occipital regions. This pain was constant, with exacerbations during the day time. It was sometimes so severe at night that she was unable to sleep. Examination showed the ethmoidal regions of both sides filled with polypi. She requested a radical operation. Nevertheless, the left side was operated intranasally, as it seemed the lesser affected, the ethmoidal cells being as far as possible removed. The left antrum was opened intranasally at the same time.

After a short interval the floor of the right frontal sinus was removed and the ethmoids exenterated. The frontal contained pus and polypi, and the ethmoids and sphenoid were filled with polypi and degenerated mucous membrane.

She made a good recovery and her pain was entirely relieved; the discharge from the right side, however, persisted. This came entirely from the antrum. Three months later the antrum was opened through the canine fossa and was found to be filled with polypi and degenerated mucous membrane. Counter-drainage into the nose was accomplished by making a window resection of the inner antral wall, extending from the floor to the middle turbinate. This method gives drainage both above and below the inferior turbinate, does not destroy the latter, and leaves an opening so large that subsequent cicatricial closure is impossible. The mouth wound was closed with silver wire, no drainage being used through either the nose or mouth. The discharge has entirely ceased. The patient has gained in weight and the anemia has disappeared. Her photograph shows the excellent cosmetic result obtained.

Conclusions.—We claim no originality for the operation we have used. It is simply a combination of the best methods. It accomplishes drainage and cures the disease equally as well as Killian's, which is, in our opinion, its only competitor.

The only valid excuse for removing the entire anterior bony wall of the frontal sinus is the presence of necrotic bone, a condition very rarely encountered in this locality.

The advantages of this operation over Killian's are: (1) Avoidance of facial deformity. (2) The dislodgment of the superior oblique tendon facilitates the removal of the floor of the sinus, especially where it extends backward a considerable distance over the orbit. (3) It is a method peculiarly suited to the treatment of cases which have perforated into the orbit with the production of orbital cellulitis. If diplopia results, it is transitory, usually clearing up in from ten days to two weeks.

We are indebted to Dr. W. F. Chappell for his courtesy in placing the cases on which this paper is based in our hands for operation.

FATALITY OF TEXTBOOK HYDROTHERAPY—A WARNING.

By SIMON BARUCH, M.D.,

NEW YORK.

A retrospect of half a century at the bedside, during which the writer has had the opportunity to make a control experiment in the uses of water in private and hospital practice, is his warrant for presenting this clinical demonstration of the danger arising from the lack of interest which characterizes the attitude of the average practitioner on this important branch of therapeutics. The control experiment referred to is the result of twenty-five years' practice without a clear knowledge of the physiological and therapeutic action of water and twenty years' observation of its effects in those diseases in which it could be advantageously utilized.

Only conviction reached in this practical manner by one who was not only a sceptic himself, but who in his early medical career was prejudiced against that misguided sect, the hydropaths, would tempt the writer to present his views so persistently to his colleagues. He is encouraged, too, by the hope of their ultimate acceptance of the truth. Again and again have I urged in many of our medical centers the vital need of more complete instruction in the remedial uses of water, based, as are other agents, upon physiological action and clinical evidence.

That these efforts have borne some fruit is gratifyingly evident in recent communications from eminent teachers, the latest of these being from Professor McRae of Johns Hopkins and Professor Billings of the Northwestern University. The latter writes: "Hydrotherapy according to your

methods is taught in our school and hospitals. All the State hospitals in Illinois practise it." That the medical profession is becoming more deeply interested in hydrotherapy is evident also from the fact that, whereas the first edition of my book was the only original treatise in the English language, there are now five American works on hydrotherapy.

The textbooks, however, are, as a rule, woefully delinquent in their presentation of water as a remedial agent. While I have repeatedly demonstrated this fact, I have hitherto refrained from pointing out that *many lives have been lost by reason of the faulty teaching of textbooks*, their reiteration of conventional methods, their indefinite statements regarding the technique, and, what is most damaging, their failure to take cognizance of published results of hydrotherapy. The following flagrant example may serve to arouse the attention of our authors on therapeutics and practice of medicine to a deeper interest in the achievements of water as a remedial agent and their more thorough presentation. That in thermic fever* many lives have actually been sacrificed by reason of unfamiliarity with the simple principles and methods of hydrotherapy I am loth to confess, but clinical records gathered in our best hospitals compel this conclusion. They are reluctantly published as a warning that faulty hydrotherapy may result as seriously if not so fatally in other diseases which are more frequent, and that writers on practice need to search the literature of hydrotherapy for additions to their resources. It would seem inexcusable temerity on my part to venture this assertion, did not the interests of humanity and of our calling demand that the truth be spoken and that the faults of conventional methods be clearly demonstrated. Moreover, the lesson from the fatality of these faulty procedures may serve to enforce my frequent pleas for the application of water on strictly physiological principles, in accordance with the indications in each individual case, and for the crying need of instruction on this subject in our schools. It is a noteworthy fact that the prevailing water treatment of thermic fever is an almost exact repetition of the false hydrotherapy of typhoid fever in vogue from 1880 to 1890. Reduction of temperature was the chief therapeutic aim and the coldest bath was erroneously regarded as the most efficient antithermic bath. The introduction of reliable antipyretics dispelled the false and fatal idea that hyperpyrexia was the chief lethal element in typhoid fever. When bedside observation established the further important fact that these antipyretics damaged the heart and excretory organs, the just anathema visited upon them was visited upon the cold bath also (as I reported in a letter from Europe to the MEDICAL RECORD in 1890). The unfortunate result was that the cold bath was modified out of all semblance to the true *antifebrile* bath devised by Ernst Brand, who was the first to inveigh against the irrational antithermic baths of Liebermeister and others and to emphasize the nerve and heart-sustaining action of the cold friction bath systematically applied.

For twenty years I have striven to establish the Brand bath as the ideal of typhoid fever management whenever the patient's reactive capacity did not forbid it. The result was gratifying, as indicated by the following brief excerpts, which may be read with advantage by doubters.

Dr. James Tyson writes: "The Brand treatment is the best available method in typhoid fever, subject to the limitations which good sense and experience demand" (*Therapeutic Gazette*, July 15, 1895). In a recent letter Dr. Tyson says: "I still use the Brand method whenever possible. Its effect is practically to make serious cases mild and mild cases much milder. My statistics to January 1, 1906, showed a mortality of 7.3 per cent., which is astonishingly like that of Osler and Wilson."

The late Dr. H. P. Loomis presented a report to the New York Clinical Society (MEDICAL RECORD, January 10, 1903) concluding: "To the Brand bath is rightly given a great deal of the credit for the decrease (50 per cent.) of typhoid mortality in New York hospitals."

Dr. Gilman Thompson ("Text Book of Practical Medicine," 1902, page 45) writes: "The Brand system of bathing as applied in this country gives astonishingly uniform results. Hence it must be admitted that cold bathing reduces the general typhoid mortality fully one-half, which certainly more than compensates for the discomfort, trouble, and expense attending this process." This is striking testimony from one who has personally experienced the latter.

History is repeating itself in thermic fever therapy. For twelve years I have endeavored to wean the medical profession from the prevalent antithermic ideas and practice in thermic fever. So far in vain. This article is written in order to achieve the consummation of my endeavors, as well as to illustrate the defective hydrotherapy of our standard works on medicine.

A review of the literature of therapeutics reveals the fact that the textbooks of to-day present the same erroneous view on the action of the cold bath in thermic fever which characterized the books in the eighties with regard to typhoid fever. A few brief excerpts from our standard works bear me out; they are worthy of being thoughtfully considered. (1) "Heat stroke, especially the hyperpyrexial forms, must be promptly treated by the application of the ice bath (ice floating in a tub of water), temperature 40° F.-4.4° C., etc." (2) "The treatment of sunstroke must be bold and vigorous; first, the temperature must be reduced until it is at a safe level by the application of ice-water or ice, etc." (3) "In the severe febrile cases the first indication is to reduce the temperature. The patient should be immediately placed in a bathtub containing ice water and pieces of ice; he should be literally packed in ice." (4) "The success in the treatment of thermic fever depends altogether on our ability to lower the temperature. For this end the patient should be placed in a bath of water to which ice is freely added to keep the temperature down as low as it can be." (5) "In true sunstroke treatment should be active and energetic, the indication being to reduce the temperature of the overheated centers. Hyperpyrexia must be combated by rubbing with ice, placing him in a tub of water with lumps of ice." (6) "In the hyperpyrexial form the vital indication is the reduction of temperature. The cold bath with ice floating in it and occasionally rubbing with ice is in my experience the best."

These excerpts are obtained at random from the most popular works on practice; they guide students and practitioners. The latest edition of another

*Deaths from sunstroke in New York City numbered 1,098 in 1896, 1,229 in 1901. During the week ending August 15, 1896, 648 deaths (one-third of the entire mortality) occurred in this city.

textbook, which has been justly honored by several translations, states: "In thermic fever the indication is to reduce the temperature as rapidly as possible. This may be done by a bath of 70° F. (duration is not mentioned). At the Pennsylvania Hospital in 1887 the ice pack was used with great advantage. Of 31 cases, 12 died, a result probably as satisfactory as can be obtained."

The idea that the coldest bath is the most antithermic and therefore the most useful has been demonstrated to be as fallacious in thermic fever as it has proven in typhoid fever. I propose to establish by absolutely reliable clinical data cited from the record made by an unprejudiced observer that textbook hydrotherapy is misleading and that its abandonment may result in as favorable a change in the prognosis of thermic fever as the same course has accomplished in typhoid fever. An unbiased review of the history of this subject leaves no room to doubt that the recognition of vasomotor depreciation as the chief danger in typhoid fever and the clinical fact that this menace to life may be most effectively met by the systematic cold friction bath administered with a view to sustain the nervous system and circulation, rather than for temperature reduction, has resulted in the reduction of mortality from 20 per cent. to 2.7 per cent. (Vogl). That a corresponding favorable change in the mortality of thermic fever has been achieved by a similar judicious change of water treatment is proven by the following report on 520 cases of thermic fever published in the *Medical News* of July 24, 1897, by Dr. Alexander Lambert, physician to Bellevue Hospital. These 520 cases represent the largest statistical record extant. Considering that 38 cases form the only statistics cited in the seven textbooks quoted above, the significance of this array of reliable data becomes evident.

Homœopathic Hospital in Brooklyn: 49 cases treated with baths of 90°, reduced gradually to 72° F., gave a mortality of 41 per cent. The same hospital in a later series treated with the needle sprays connected with the cold faucet until rectal temperature fell decidedly.

Bellevue Hospital: 200 cases treated with ice baths, mortality 33 per cent.

Flower Hospital: 26 cases treated with needle sprays connected with the cold faucet, until rectal temperature fell to 101° F., mortality 11.5 per cent.

St. Vincent's Hospital (O'Dwyer): 197 cases treated with affusions of ice water and frictions to stimulate, stopping when rectal temperature reached 102° F., mortality 6 per cent.

It appears from this record that under incorrect (antithermic) treatment the mortality ranged from 33 to 41 per cent., while under correct (stimulating) hydrotherapy the mortality was 6 per cent to 11 per cent.

From an analysis of these, the largest records on the subject ever published, the deduction is inevitable that the most efficient procedures were those directed to neutralizing the vasomotor depreciation. In conclusion I desire to dwell on the fact that the most popular American textbook on practice has reiterated in each of its six editions the statement that a mortality of 12 out of 31 cases (treated in 1887 by ice packs) is "the best result to be expected in this grave disease," and that the vastly superior achievement of a mortality of 6 per cent. in 197 cases (treated in 1896 by cold affusions) appears to be unknown to all authors within my reach, despite the publication of these data in a prominent medical journal and their emphatic reproduction in three editions of my book.* Nor do these remarkable statistics receive mention in a series of prize essays on sunstroke published in the *New York Medical Journal* in 1908. It goes without saying that if such remarkable results had been achieved by a medicinal agent or serum they would have been heralded in every book on therapeutics and practice of medicine.

The futility, nay the reprehensibility, of depending upon the average textbook for information on hydrotherapy is clearly demonstrated. The material and humane interests of medical men would doubtless be furthered by resorting to some good book on hydrotherapy when in search of counsel in the treatment of any disease. By scanning the index of such a work the practitioner may obtain information of great and unsuspected value to himself and his patient. This is the only direct and simple way for the physician to familiarize himself with a subject which has been neglected or treated faultily in his books of reference, and which is just beginning to be taught properly in our schools.

Authors of textbooks also would render their works more complete and satisfying if they would take cognizance of hydrotherapeutic literature, selecting the golden grain from the inevitable chaff, as they do with regard to other remedial agents.

135 West Seventy-third Street.

THE TREATMENT OF PULMONARY TUBERCULOSIS BASED ON THE ASSUMPTION THAT THE DIETETIC CAUSE OF THE DISEASE IS LIME STARVATION.

SECOND REPORT OF RESULTS.

By JOHN F. RUSSELL, M.D.,

NEW YORK.

The preliminary report of results was published in the Medical Record, November 27, 1909, and the hypotheses upon which the treatment is based in the Medical Record for December 18, 1909. The reader is referred to these papers for a full description of the treatment, classification of patients, arguments in support of the hypotheses, etc. For the better understanding of this article a few of the facts are briefly reviewed in the following:

The patients are self-supporting working people and are treated without interruption to their work, the dispensary hours being arranged with this end especially in view. Patients with uncomplicated pulmonary tuberculosis, in any stage of the disease, are admitted whose evening temperature is below 101° and who are clearly not too weak to make the journey from their homes twice daily; who can provide proper food, clothing, and shelter and who live within reasonable distance of the dispensary. When other symptoms are favorable patients whose evening temperature is 101°, or more, are accepted provisionally because it has occasionally been found that, after one or two weeks of treatment, the temperature falls and remains in the neighborhood of 100°. An evening temperature of 100° and 100.5° is not a bar to treatment. No patient with laryngeal tuberculosis in the stage of ulceration is admitted for treatment. No patient is admitted whose sputum does not show the presence of tubercle bacilli. Patients are considered apparently cured when physi-

*"Principles and Practice of Hydrotherapy," Wm. Wood & Co., p. 384

cal signs of disease are no longer present and tubercle bacilli have disappeared from the sputum. Tubercle bacilli are considered to have disappeared when six consecutive examinations, two weeks apart, fail to show their presence.

RESULTS
Thompson Street Dispensary

Class.	Number.	Per Cent.	APPARENTLY CURED.	
			Number.	Per Cent.
Incipient	0	0	0	0

Far advanced	13	27.6	7	53.8

The most important question next arises, "Do these people, apparently cured under these circumstances and still continuing to work and live in the city, hold their improvement?"

The National Association for the Study and Prevention of Tuberculosis defines "cured" as follows: "All constitutional symptoms and expectoration with bacilli absent for a period of two years under ordinary conditions of life." According to this definition sufficient time has elapsed to report the ultimate result upon 20 of these apparent cures.

REPORT OF REEXAMINATION OF PATIENTS TWO YEARS OR MORE AFTER APPARENT CURE.

Case No.	Date of Re-examination	Condition of Lungs	Present Weight	Tubercle Bacilli in Sputum*	General Health	Present Occupation	Remarks
15	May 27, 1909	No abnormal signs	145½	Absent †	Good	Foreman	Ischiorectal abscess September, 1907. Healed.

* Sputum examined each day for three successive days.
† These patients are able to work and are again under treatment.

There remain 21 patients still to be reported upon.

Even though the work of the experiment is not yet finished the percentage of cures so far obtained is greater by this method of dispensary treatment, carried on without interruption to work, than the percentage of cures obtained at sanatoria, as shown by the following table. This table is compiled from an article by E. W. Bullock, M.D., in collaboration with C. T. Sands, M.D., published in the *Journal of the American Medical Association* June 19, 1909:

As there are no incipient cases in the Thompson Street Dispensary statistics, no comparison of results of treatment in this class can be made.

Patients in the incipient stage are not commonly seen in dispensary practice, and such as applied at the Thompson Street Dispensary failed to show tubercle bacilli in their sputum and were, on that account, denied treatment. The reason for declining to admit such patients for treatment is that, in an investigation of this kind, undertaken with the object of determining the merits of a particular treatment, the selection of patients whose sputum contains tubercle bacilli at the beginning of treatment and insisting that they shall have disappeared at the end is an essential safeguard against error in classifying patients as apparently cured. The great majority of tuberculous patients who apply to all physicians for treatment are advanced in disease. The extensive lesions found in the patients here reported upon are typical of those commonly observed in general practice. A much more reasonable comparison of results between sanatoria and the Thompson

Thompson Street Dispensary.	47	26	55.3

*These figures are evidently a misprint.

It is possible that the comparison between the advanced cases of the sanatoria and those of the Thompson Street Dispensary is unfair to the sanatoria because some of their patients may have had continuous fever, while those at the dispensary had not. A patient with continuous fever cannot properly be treated at a dispensary. When, however, it is considered that all the incipient cases, many of whom did not show tubercle bacilli in the sputum, are included in the statistics of the sanatoria, it is more than probable that this error is offset, and the comparison, as a whole, is fairly accurate. It is manifest that the cases classified as incipient are ideal subjects for dispensary treatment, and the results so far obtained in the dispensary treatment of advanced cases leave no room for doubt as to the result to be obtained in the treatment of incipient cases.

The table given above shows that the highest per cent. of apparent cures in all patients treated at sanatoria is 34, the lowest 5.07, while at the Thompson Street Dispensary the per cent. is 55.3. The sanatorium showing the highest per cent. of apparent cures in all cases is the New Mexico Cottage Sanatorium, where the average cost per patient for nine months' treatment is said by the physician-in-chief to be nearly $1,000.

In view of these comparative results certain ideas at present current concerning the management of the tuberculous should be radically modified. Obviously an immense amount of industry and money are being misdirected.

The care of the dependent and the well-to-do is arranged for, but there is no provision for wage-earners. So far as treatment which wage-earners may follow is concerned, this class is as completely ignored as if the disease were considered never to exist among them. For example, it is taught that rest and an outdoor life are necessary conditions for the successful treatment of tuberculosis.

In "The Campaign against Tuberculosis in the United States," published under the direction of the National Association for the Study and Prevention of Tuberculosis, 1908, there are mentioned 250 special sanatoria and hospitals, and more than 150 dispensaries. Wtih the possible exception of one or two dispensaries wage-earners cannot receive systematic treatment in any of these institutions unless they cease to be wage-earners.

It does not appear that dispensaries suggested by the National Association for the Study and Prevention of Tuberculosis are intended for the treatment of curable cases. In a leaflet describing briefly the aims of the National Association the following statement appears under the heading "Hospitals and Sanatoria." "By procuring the establishment, on an adequate scale, of hospitals for advanced cases of consumption, sanatoria for the cure of curable cases, and dispensaries for early diagnosis and as centers of visiting, nursing, and instruction in the homes of the poor."

This same leaflet under the heading "Results" says they have established over "15,000 beds for curable cases in 400 sanatoria for the open air treatment, the opening of nearly 300 dispensaries with more than 500 physicians in attendance, and with over 500 visiting nurses giving instruction in the homes of the patients."

There are 549 patients classified as incipient cases in the tables of the sanatoria just quoted, all of them presumably wage-earners, or who certainly were in condition to work, who might be treated at home without interruption to their work, or business, maintaining their familes, and holding their place in the struggle of life.

The only logical conclusion to be drawn from these tables is that all ambulant cases should be treated in dispensaries and the work of sanatoria restricted to the care of advanced cases with continuous fever or complications which necessitate rest.

"A smith, reply'd I, when he falls sick, thinks it fit to take from the physician some potion, to throw up his disease or purge it downward, or by means of caustic or amputation to get quit of his trouble; but if any one prescribe for him a long regimen, putting caps on his head, or other such things, he quickly tells him that he hath not leisure to lye sick, nor doth it avail him to live in this manner, attentive to his trouble and negligent of his proper work; and so, bidding such a physician farewell, he returns to his ordinary diet, and, if he recovers his health, he continues to manage his own affairs, but if his body be not able to support, he dies, and is freed from his troubles."

"It seems proper, said he, for such an one to use the medical art in this manner."

"Is it not, said I, because he hath a certain business, which, if he doth not perform, it is not for his advantage to live?" Plato's "Republic."

185 Madison Avenue.

THE TECHNIQUE OF URETHRAL EXAMINATIONS.*

By WALTER S. REYNOLDS, M.D.,

NEW YORK.

CHIEF OF CLINIC AND INSTRUCTOR IN GENITOURINARY DISEASES, COLLEGE OF PHYSICIANS AND SURGEONS (COLUMBIA UNIVERSITY).

In the presence of a chronic urethral discharge, perhaps so slight as to be found at the meatus only on awakening in the morning, and giving rise to flakes and shreds in the urine, the diagnosis of chronic urethritis is ordinarily easily made. Such a diagnosis is seldom, however, sufficient for a proper and efficient treatment, and if we are to be successful in the application of remedial measures we must go further in our endeavor to determine, not only what the condition of the urethra is, but also the location and extent of the process. It would be about as reasonable to treat a sore throat, without a preliminary examination, as to treat a chronic urethritis without knowing the condition of the urethra. And

*Read before the Society of the Alumni of the City (Charity) Hospital, February 8, 1911.

yet, in spite of all that has been written and said on the subject, and the ease with which it is possible for a correct diagnosis to be made, if only a few simple measures are intelligently carried out, we are frequently seeing cases of this sort where apparently little effort has been made to correctly diagnose the cause of the trouble. I propose, therefore, to again bring to the attention of those who are interested in obtaining results in the treatment of such cases, a method of examination which I have been for some time in the habit of using, and which, I can assure those who will follow it, they will find satisfactory. All methods of examination are subject to modification at times to suit particular requirements, and at times this will be necessary in the method which is advocated here. But ordinarily the method is one requiring little or no modification.

Before proceeding to any examination a full and complete history should be obtained covering the following points: Previous history as to urethritis or syphilis; present history as to duration and history, incubation, and present condition. In this form I have followed one which has been in use at

Irrigation of urethra, recumbent position.

the Vanderbilt Clinic for some time and serves admirably where details are filled in with sufficient fullness.

Taking up first the previous history, this should cover the following points: Number of attacks? First attack how long ago? Duration? Mild or severe? Complications? Treatment? Cured? Each subsequent attack or relapse must be fully covered in the same way. I wish again to emphasize the importance, as I have done in other publications, of learning the *facts* regarding a man's syphilitic history. When a man says he has had a chancre we must not immediately jump to the conclusion that he has had syphilis. Learn all that is possible concerning it; how he knew it was a chancre; its incubation (this is seldom possible to learn, and one can usually only say that the lesion appeared so long after the last intercourse); how it looked, and what course it followed. The treatment should be inquired into, and most important of all, whether the chancre was followed by a secondary rash (and whether this was ever looked for by the physician in attendance). In this connection it is important to learn whether treatment was begun as soon as the lesion appeared, as this might influence the evolution of the secondary manifestations. If all these points are inquired into one will frequently be surprised to learn in what sort of manner this disease is treated.

Having learned as much as possible concerning the previous ailments, we are in a position to begin the consideration of the present trouble. This should cover much the same ground as in the previous attacks. More especially the things we wish to learn and the reasons are as follows: The duration: Providing the duration has been short (in the absence of former attacks), the less likelihood of stricture formation and, therefore, the greater expectation of prompt results. The severity: The greater the severity the more damage to the urethra. Frequency of urination: During the early stage this is generally proportional to the severity of the inflammation. If there was an increased frequency of urination, occurring also *at night,* it is an indication of inflammation of the posterior urethra. In the first week of a urethritis, when the posterior urethra is not involved, painful erections are frequent and will awaken the man; urination relieves the erection, and this may seem like posterior urethritis to a careless observer. Posterior urethritis in a large proportion of cases, if not all, is accompanied by prostatitis or seminal vesiculitis. The discharge: It is essential to determine the character and amount of the discharge. The patient's statement should not be accepted for this, but an inspection of the parts should be made so that the physician can be assured of their correctness. For the proper estimate of both the character and amount of discharge, the examination should be made a considerable time after urinating. A discharge which is markedly purulent indicates a more inflammatory lesion than one which is more mucoid in character. The more abundant the discharge the more extensive the lesion.

Method of Examination.—A sufficient length of time having elapsed since urination, the physical examination can be begun. The examination should never be undertaken when the man has only recently urinated. Four or five hours is usually sufficient time after having urinated, but if possible, I prefer to have the man report in the morning without having urinated. The man stands before the doctor—having removed his coat and vest and letting the trousers fall to the knees, and rolling the shirt well up above the abdomen. In this way one can see at a glance whether there is any abnormal condition showing. The inguinal glands, the cords, the epididymis, and the testicles are next examined. Two clean glass slides and a sterile platinum loop having been made ready, the meatus is examined to see the amount of gluing present. Next the character and amount of discharge is observed. If there is none present at the meatus, gently stroking the urethra from behind forward will be sufficient. A loopful of secretion is collected and transferred to the two slides and spread evenly in a thin smear over them, and reserved for future examination. The next step consists in washing out the anterior urethra and freeing it from all secretion which has accumulated there. A warm solution of boric acid or sterile salt solution having been prepared (12 to 16 ounces is usually sufficient), the man stands, holding a clean basin beneath the penis with one hand, while the penis is supported by the fingers and thumb of the other hand. A small, sterile, straight,

soft rubber catheter of about No. 10 or 12 F. is lubricated with a soluble lubricant and passed gently into the urethra until the eye of the catheter rests in the bulbous portion. The nozzle of the syringe is now attached to the end of the catheter and the solution injected through the catheter escaping from the eye and flowing forward, washing out the urethra, and being caught in the basin which is held by the patient. In selecting soft rubber catheters for this purpose it is preferable to have one about six or seven inches long. It should be of good-sized caliber and yet have sufficient rigidity. I prefer one with funnel end, and have catheters of this sort especially for this purpose. In like manner I prefer a hand syringe of four ounces capacity, Professor Hayden's being an admirable one for the purpose. It is especially useful, as it is furnished with a stopcock which controls the flow of the fluid. A syringe is not necessary, as an irrigating jar can be used instead. Whatever form of apparatus is used, the irrigation should be continued until the fluid returns clear. Too much force must not be used lest the resistance of the compressor urethra muscle be overcome and the fluid carried into the bladder. After the urethra has been thoroughly washed out, the fluid collected in the basin is poured into a clean glass cylinder and set aside for examination. In some cases, where the man is nervous, the examination should be made with the man lying down. The anterior urethra being absolutely free of all secretion, the man passes into a clean glass cylinder only a small quantity of urine. This is examined for flakes and shreds by being held up to the light, and if not absolutely clear a further specimen is obtained. This being clear, and the man having some urine still in the bladder, the prostate and seminal vesicles should be examined, and gently massaged. The massage is performed with the man standing, his body bent forward at a right angle, one hand resting on a stool and the other hand holding beneath the penis a small graduate with a good-sized opening. The index finger, protected with a rubber finger cot, is well lubricated, and gently inserted into the rectum. The prostate is mapped out: its size, shape, and consistency determined, and the amount of tenderness ascertained. A gentle massage, from the base to the apex, is done, and the vesicles examined in the same way. If any fluid presents at the meatus it is caught in the graduate or on a glass slide. The balance of the urine is finally passed into another cylinder for examination. The result of the examination is as follows: Specimen No. 1: Two slides with secretion from meatus. Specimen No. 2: Cylinder containing washing from anterior urethra. Specimen No. 3: Cylinder containing urine and secretion from posterior urethra. Specimen No. 4: Cylinder containing clear urine. Specimen No. 5: Secretion from prostate Specimen No. 6: Cylinder containing urine and secretion from prostate.

So far the urethra has been examined to determine only what areas are affected; that is, whether it is confined to the anterior urethra or whether both the anterior and posterior urethra, and perhaps the prostate and vesicles, are involved. The further examination will depend somewhat upon the history of the case and the result of the examination. Examining the cylinders, we find that cylinder No. 1 is very faintly turbid, and contains numerous flakes and shreds. This indicates that there are areas in the urethra from which the flakes and shreds have been washed, and in the absence of marked discharge and only faint turbidity of the fluid, indicates a chronic anterior urethritis. This fluid should be centrifuged and examined microscopically to determine whether the turbidity of the fluid is due to mucus or pus, and also stained and examined for microorganisms. Cylinder No. 2 contains the secretion from the posterior urethra. It will contain flakes and shreds in a clear urine if there is a chronic posterior urethritis. The specimen should be centrifuged and examined microscopically in the same way as cylinder No. 1. In some cases this specimen may be found markedly cloudy. If specimen No. 4 is in the same condition it should be examined for the ordinary things causing cloudiness of the urine. These are: Phosphates, carbonates, urates, pus, and bacteria. The urine in the third cylinder was obtained to be sure that the posterior urethra was freed from secretion. This leaves specimens Nos. 5 and 6 for examination; these are specimens of prostatic secretion. No. 5 is the secretion which has been expressed at the meatus as the result of the massage. No. 6 is the secretion which has been washed out by the passage of the balance of urine in the bladder. These specimens are to be examined in the same manner as the previous ones.

If the disease is of recent origin and a first infection we would hardly expect to find evidence of stricture formation; if, however, the attack has been a prolonged one and there have been several previous attacks, the urethra should be explored for the presence of stricture. This should always be done whether there are symptoms of stricture or not, for stricture of large caliber may give rise to no marked urinary symptoms. For exploring the urethra for stricture a bougie-à-boule and sounds are necessary. If the meatus is small a preliminary meatotomy is necessary. A bougie-à-boule as large as the meatus will comfortably accommodate is sterilized and lubricated with a soluble lubricant, and carried down the urethra until it reaches the bulbous portion. If any obstruction is found to its passage a smaller instrument is taken, and passed in the same way. If this passes the obstruction we have determined the site and size of the stricture of the anterior urethra. A good-sized sterile steel sound is now passed to determine whether there is any obstruction in the bulbomembranous region. To determine the exact condition of the urethral mucous membrane, urethroscopy must be done. This is perhaps a little difficult for one who has not had very much experience in this branch of work, but with the very simple and ingenious instruments now manufactured it should not offer very great difficulties. If thought best, the exploration of the urethra by bougie-a-boule, sound, or urethroscopy may be left to subsequent visits, and frequently this is a wise thing to do. As has already been stated, in recent cases of first infection an examination of the urethra for stricture is seldom indicated, the infiltration in these cases being soft and usually gradually absorbed as recovery takes place under treatment. Specimens Nos. 1 and 5 are to be stained and examined in the manner already described. Specimen No. 1 consists of two slides. If the first one examined contains intracellular diplococci a second slide can be stained and decolorized to determine whether or not they are gonococci.

This examination may seem somewhat long and difficult and hardly worth the time and trouble entailed in its execution. If, however, we are to treat these cases in an intelligent manner, our diagnosis must be founded on some conception as to what has taken place in the urethra. For those who compare urethritis to a hard cold it can have no interest.

A DEPARTMENT OF INSURANCE MEDICINE.

DURING the past fifty years a very important specialty in medicine has been developed quietly and almost unnoticed by the profession at large. It is practically ignored in the curriculum of many colleges, notwithstanding the fact that it is a highly developed science and one that demands peculiar qualities and special training on the part of those engaged in it. It has not even a definite name, insurance medicine being perhaps the term most nearly expressing it, yet it embraces more than that implies, since it may be held to include everything relating to the determination of the physical and even mental fitness of men for the various positions of life. It includes not only the examination of applicants for life insurance and the determination of their acceptability as good risks, but also the examination of recruits for the army and navy, of candidates for appointment to the municipal police and fire departments, of railway employees, pilots, and even college athletes. The qualities it demands in those who follow it are of the highest order. Not only must they be diagnosticians and experts in physical examination, but they must possess a discriminating judgment enabling them to deal not alone with the individual *per se*, but with his relation to the mass of humanity. They must know the law of averages as well as the constitution of the individual man. In medicine pure and simple it is the man himself who is to be considered primarily; the practising physician should indeed be acquainted with the broad principles of disease, but in treating his patient in any individual case his first care must be for the individual, and his study must be how the individual reacts to the adverse forces which threaten his well-being or his life. The insurance physician, on the other hand, though not ignoring the individual, pays most attention to the disease. He has to deal largely with averages. Though he knows that an individual may recover from a certain disease, he is obliged to overlook that possibility and to regard rather the general history of the disease in question and its usual effect in the shortening of life. But his is no fixed science, for with the advance in therapeutics and hygiene, the averages with which he deals are constantly changing, and a risk which, in the present state of medical knowledge, may to-day be rejected will perhaps, in ten years or in five, be regarded in an altogether different light. Insurance medicine is, therefore, constantly changing, keeping progress with the advances in general medicine, just as are all the other specialties.

These and other considerations, which cannot now be dwelt upon, but will be taken up from time to time as occasion demands, have led us to believe that the reestablishment of a department of Insurance Medicine in the MEDICAL RECORD would be welcomed by our readers. Thirty-eight years ago we introduced such a department, which was continued for some years. It was favorably received and awakened much interest among those of our readers who were connected with life insurance, either as medical directors or as examiners. In an address before the American Medical Editors' Association last year, Mr. Hoffman of the Prudential Insurance Company referred with appreciation to this department, and said that "even to-day, more than thirty years after, some of the discussions upon questions of insurance medicine contributed to that journal at that time remain a source of useful information not otherwise accessible, even in the textbooks on the subject." The number of insurance examiners at that time was comparatively small and the science was in its infancy, and although there was no lack of interest manifested by the contributors to it, their number was too small to warrant its continuance. To-day the conditions are different; it is estimated that there are eighty thousand physicians in this country and Canada regularly engaged in making insurance examinations; the medical directors of insurance companies do not, as a rule, combine private practice with their insurance work, but are pure specialists, working with the actuaries and statisticians in developing a science of medico-insurance, closely allied to and dependent upon, yet distinct from, the science of medicine in its practical relation to the treatment of disease. The insurance examiners, however, are, as a rule, physicians in actual practice, who often do not fully understand the science of medical insurance developed by the medical directors of their respective companies. It is evident that a fuller understanding of this science and an appreciation of the mutual relation between the examiners, scattered throughout the country, and the medical directors in the home offices of their companies will bring the two branches of this specialty nearer together, and will lighten the labors of both.

With the object, therefore, of bringing these two classes of workers in medical insurance in closer accord, and of promoting their common interests, the MEDICAL RECORD has reestablished the Department of Insurance in its columns. It is proposed to devote such space as may be necessary, each week, to original communications and editorial articles treating of insurance matters, to abstracts of articles on this specialty appearing in other journals, to news relating to the medico-insurance world, and to correspondence from medical directors and examiners on topics of mutual interest. The department will include all subjects relating to health and accident, as well as life insurance, to the physical

examination of recruits in the army and navy of this and other countries, of candidates for appointment in municipal fire and police departments, of railway employees, etc., to fraternal societies and medical clubs; in a word, to anything bearing upon this specialty in medicine. We promise to do our part in furnishing our readers with full abstracts, constituting an index medicus of articles appearing in journals throughout the world which bear upon insurance medicine and physical examination, and we trust to our readers who have to do with the subject to contribute articles and correspondence which will further this most important branch of the science of medicine.

CAUSATION OF AMENORRHEA.

While our knowledge of the conditions under which amenorrhea occurs is doubtless on the increase, we are still in almost complete ignorance of the causation and nature of the phenomenon. These were once supposed to be self-evident, and it is the increased number of conditions in which amenorrhea is now known to occur that has changed the problem from a seemingly simple to one complex and obscure.

At a recent session of the Aerztlicher Verein of Munich, Rosenberger dealt exhaustively with this subject (*Münchener medizinische Wochenschrift*, April 25). It is necessary, he said, to study the amenorrheas of pregnancy and the climacteric—the so-called physiological types—in connection with the pathological types. Glycosuria is common at some period of the reproductive sequence, including the puerperium and lactation, and tends to recur in subsequent pregnancies of the same subjects. The author sees some relationship between this phenomenon and the suppression of the menses. It is also well known that the diabetes which sets in at the menopause is chiefly of a benign type. Another metabolic disturbance is the notable gain in weight in early pregnancy which is in accord with the same phenomenon at the menopause. These gains are often transitory. Hypertrophy of the turbinate bones is common in gestation. To explain this feature it is necessary to invoke the aid of phenomena noted in prehistoric and savage man, the primates, etc., extending in the evolutionary ladder as far back as fish, to wit, a tendency to hypertrophy of the cranial and facial bones during the period of sexual activity. This may be brought in relationship with certain disturbances of the optic nerve, such as hemianopsia, amaurosis, and in rare cases retrobulbar neuritis and optic atrophy. These disturbances have no necessary relationship with albuminuria and the toxemia of pregnancy. On the contrary, the author traces a purely mechanical connection between the ocular phenomena and enlargement of the hypophysis.

We have thus far a tetrad of symptoms associated with physiological suppression of menses, viz., glycosuria (nondiabetic), obesity, hypertrophy of the facial bones, and ocular disturbances. The author now seeks to connect all these phenomena with the physiological hypertrophy of the hypophysis. Acromegaly, which results from such hypertrophy, is becoming increasingly frequent. It is accompanied by suppression of the menses and is the most striking type of pathological amenorrhea. Enlarged hypophysis explains the turbinal hypertrophies, the ocular symptoms, and probably the other symptoms.

Rosenberger's paper received a very full discussion. The old view that the presence or absence of menstrual bleeding was due solely to the maturing or failure to mature of an ovum is necessarily sidetracked by such a theory, although not necessarily controverted. The view of Rosenberger makes of menstruation more than a phenomenon peculiar to women, and suggests an analogy with the periodicity of mental activity in man, concerning which much of interest has been written. Writers and artists have days in which work is easy or difficult, respectively, dependent in all likelihood on wavelike alterations in the circulation. Fluctuations occur not only in the mental activity of man, but simultaneously in certain other functions.

TYPHUS FEVER.

The recent occurrence of epidemics of typhus fever in the vicinity of Odessa resulted in a thorough discussion last March of that disease by the Society of Russian Physicians of the said city (*Münchener medizinische Wochenschrift*, May 16). Professor Levashoff is said to have discovered in 1892 the *Micrococcus exanthematicus* in the bodies of patients dead of the disease. The discovery attracted little attention because cultures could not be obtained. In 1909 Potgsenko, assistant to Professor Levashoff, succeeded in obtaining a pure culture of the micrococcus from human bone-marrow; and two years later he was able to detect the same in the blood.

Potgsenko sees no evidence that the disease is transmitted by the clothes louse, a hypothesis put forth by Gamaleïa. The cultivation of the micrococcus, accomplished after many years of patient study, is pronounced by Levashoff one of the greatest of bacteriological feats. Cultures may be made in routine from the bone marrow, but it is only occasionally that blood cultures are successful. The micrococcus is exceedingly small, sometimes requiring a magnification of 3,500 diameters to make it visible. Its natural habitat as a pathogenic agency appears to be the blood. The contagiousness of this disease is extreme, he says, and in its ability to attack every member of a household, and every family in a village, it is surpassed, if at all, by the bubonic plague alone, to which also it is second in its percentage of fatalities. The contagion is believed to depend, as in the pulmonary form of bubonic plague, upon the massing of germs in the respiratory, especially in the nasal and conjunctival, mucosæ.

That the Russian physicians would test 606 in typhus fever was a foregone conclusion, and this is now being thoroughly done. Thus far the outlook seems highly encouraging, and it is believed that the drug has a natural bactericidal power over the germ. The exhibition has been wholly intravenous. Uskoff reports fourteen recoveries, apparently 100 per cent. Nine patients had the disease in a severe form. The Ehrlich-Hata preparation would seem

to be an heroic remedy, for more or less severe collateral effects were commonly seen after individual injections. The heart was distinctly weakened for the time being. The fourteen patients received twenty-four injections, the highest individual dose was 0.9 gram. A few patients received two or three injections. Defervescence followed the exhibition of the remedy after some hours. The drug has already been tested in bubonic plague, and is said to bring about prompt defervescence and disappearance of bacilli from the sputum. The patients, however, invariably have succumbed to heart failure. Typhus fever is an affection of much longer natural duration and may, therefore, be more amenable to treatment. The Odessa results seem better than those obtained under any other method hitherto employed except possibly the open air treatment.

FAMILIAL KERATITIS.

The French expression familial, as applied to disease, is usually synonymous with family, hereditary, ancestral, and the like, and has become Anglicized. Thus when either a disease *per se*, or a disease with so-called equivalents, occurs in members of several successive generations of a large stock of individuals it may be termed by one author "familial," by another "family," by a third simply "hereditary," by a fourth "ancestral," a lay expression. There is a well-known incidence of disease in which the children, all or part, of perfectly healthy parents and other ascendants, without so-called equivalents of any sort, may alone suffer. If these children grow up and marry, the disease may be transmitted to the descendants, although the possibilities of such transmission have yet to be studied. It would perhaps be well to restrict the term familial to designate a taint in numerous generations, while unifamilial might be employed to denote the incidence of a disease in the children of one family.

At a meeting of the Berlin Ophthalmological Society, recently held (*Berliner klinische Wochenschrift*, April 10), Clausen reported a case of "familial keratitis." In 1905 Fleischer had first described a "family degeneration of the cornea," evidently the same condition. The affection appears in the first decade of life, is bilateral, and occurs in either sex. A considerable number of examples have now been reported, and the affection is probably more common than has been believed. This would be suggested by its polymorphous character (nodes, macules, etc.) The lesions progress and reach the limbus. The condition seems to be due to the deposit of hyalin in the cornea, but the nature of the process is quite obscure.

It is not stated whether the affection was unifamilial or multifamalial. In this connection it might be well to emphasize the possibility that a unifamilial affection may have no connection whatever with an ancestral taint. There may be neither skipping of generations nor hereditary equivalents. In such a condition we are reminded irresistibly of Mendelism in as far as this deals with the formation of new species. A unifamilial affection should, therefore, by all means be looked after in the descending generations.

A Simple Measure of the Normal Size of the Heart.

The *x*-ray study of the heart has rendered possible the determination with a greater degree of exactness than hitherto possible, of the normal size of this organ and of the correlation of this size with the body weight and height, and with the sex and age. Useful tables have been constructed, by means of which it is possible to recognize with greater ease certain variations from the normal size of the heart. A method that will render the consultation of these tables unnecessary, has been worked out by Levy-Dorn and S. Mäller, who describe their results in the *Zeitschrift für klinische Medizin*, Volume 72, Nos. 5 and 6. The former of these observers had announced this method one year ago, but at that time his studies were based upon scant material. More recent and extensive observations have confirmed the earlier findings. There are two means of determining the normal length of the heart. In the first of these, the patient is required to close his right hand like a fist, with the interphalangeal joint of the thumb resting on the first interphalangeal joint of the index finger. The distance from the ulnar border of the meacarpophalangeal joint of the little finger to the dorsum of the interphalangeal joint of the thumb is measured by means of a vernier or calipers; this distance, if multiplied by one and a half, gives the length of the heart. The second method consists in adding to the breadth of the hand, as measured between the metacarpophalangeal joint of the index finger and that of the little finger, the length of the first phalanx of the middle finger. This sum gives the length of the heart. Both of these methods furnish a simple and practical measure of the size of the healthy heart, the length of the latter being about one centimeter less than the figures obtained by the hand measurements. The relationship between the heart and hand remains constant irrespective of the age or sex of the person examined. The value of the above methods of estimating the normal size of the human heart is obvious, particularly as a means of comparing the actual size of the diseased heart, as mapped out by percussion, with that of the normal organ.

Chloride of Ethyl as a General Anesthetic.

Aristide Malherbe, assistant surgeon to the National Institute for the Deaf and Dumb, Paris, writes in the *Medical Press and Circular*, May 3, 1911, in praise of chloride of ethyl as a general anesthetic. He has administered it since 1900, by the compress method, and emphasizes his belief that even for long operations chloride of ethyl can be employed, and that it will eventually supersede chloroform and ether owing to the greater margin of safety. Malherbe and Boureau have together administered chloride of ethyl as an anesthetic in 6,275 cases without a death or without any disquieting symptoms. All the phenomena accompanying anesthetization by chloride of ethyl are fugitive, and the subject at once "comes to himself" with a clear brain and with no unpleasant symptoms. Furthermore, the drug does not seem to have any effect on the digestive tract. Another point in its favor is that it is tolerated as well by infants as by adults and old people. Malherbe employs the compress method exclusively, preferring it to any of the various forms of application in use. A compress or handkerchief, folded in four thicknesses, is held

in the palm of the right hand, which is hollowed out to receive it. Into the hollow a jet of chloride of ethyl is projected from a graduated tube made for the purpose. The compress is then at once firmly applied over the mouth and nose of the patient, who is instructed to breathe deeply. The head and lower jaw are supported by the left hand. It is necessary not to allow any air to be breathed. The lack of untoward results from the administration of this agent in 6,275 cases of anesthesia is a good record and would seem to indicate that the use of this anesthetic may be advisable in certain cases if it is properly and carefully administered.

Permanent Tonsil Infection.

The tonsils have long been accused of causing the greatest variety of systemic affections either through serving as passive ports of entry or as themselves the seat of a local infection which can become general. Among the alleged results of tonsillar infection are tuberculosis, acute rheumatism—including cardiac complications and chorea—sepsis, appendicitis, etc. Pässler (*Münchener medizinische Wochenschrift*, May 2, page 977) applies the term permanent infection to chronic tonsillar cryptites, with formation of secretion and tonsil plugs, which condition he believes may be responsible in part for the above mentioned infections. The chief argument against the tonsillar hypothesis has always been the very small percentage of positive findings. There is no doubt that after tonsillectomy certain chronic or recurring lesions at remote localities have often improved, and tonsils in a condition of permanent infection should certainly be cured on general principles. Every crypt should be destroyed, although this may be sometimes effected without extirpation. Pässler evidently does not regard the tonsillar condition as in any way specific for causing general infections. We extirpate pyogenic foci here just as we should in and about the alveoli of the teeth, the nasal sinuses, pharyngeal tonsil, uterine adnexa, appendix in recurrent appendicular suppuration, etc.

News of the Week.

Charitable Gift.—The New York Milk Committee has received a gift of $7,000 for the support of its central office and for its general educational work.

Antityphoid Precaution.—The New York State National Guardsmen who are scheduled for camp duty at Pine Plains, N. Y., during the summer, are to be inoculated with antityphoid serum on their arrival at camp as a precautionary measure. While the inoculation is not obligatory it is believed that at least 90 per cent. of the men will submit to it.

Cholera in New York Port.—Two steamships arriving from Mediterranean ports were held at Quarantine in New York during the past week because of cases of cholera. On the *Duca degli Abruzzi* which arrived on June 20 there were four cases, one child dying at sea, and two others after arrival at Swinburne Island.

School for Midwives.—The Bellevue Hospital School for the Training of Midwives will be opened by the trustees of Bellevue and Allied Hospitals July 15, 1911. The teaching will be under the direction of a Resident and an Assistant Resident Obstetrician, who will receive respectively salaries of $1,200 and $900 per annum, with maintenance. No civil service examination is required. A knowledge of German and other foreign languages is very desirable, but not absolutely essential. Candidates may apply by letter, giving qualifications, to the president of the Board of Trustees, Bellevue Hospital, New York.

Smallpox in Yukon.—Governor Clark of Alaska has appealed to the Federal Government for aid in preventing the spread of the epidemic of smallpox in Dawson City south into American territory. Officers of the public health service in Alaska have been instructed to establish quarantine at Eagle City and Skagway. The epidemic is regarded as serious, particularly as at this time of the year prospectors from Yukon Territory are going into Alaska in large numbers.

Inoculated Monkeys Escape.—Two monkeys which had been inoculated with scarlet fever escaped from the Willard Parker Hospital, New York, on June 23, and their escapade created great excitement. One was finally recaptured in a shop on East Fourteenth street, while the other was found on a barge in Gowanus Canal.

Infant Mortality.—Commissioner Lederle of the New York Department of Health announces that all of the public school nurses have, with the closing of the schools, been assigned to duty under the Division of Child Hygiene of the Department in the effort to prevent the usual high infant mortality during the summer. The work will be carried on in special districts where the mortality has been the highest. For the first five months of 1911 the death rate from all causes of children under one year was 120 per thousand, exactly what it was for the same period of 1910. The deaths from diarrheal diseases, however, increased 35 per cent. during this time, a corresponding decrease in the deaths from congenital and infectious diseases taking place. During the week ending June 10 there were 37 deaths from diarrheal diseases among babies under one year of age in the entire city, as compared with 43 for the corresponding week of last year, while for the week ending June 17 the figures were 50 deaths for 1911, and 91 for 1910.

Christian Science Healer Held.—Mr. W. B. Winslow, a Christian Scientist, who was arrested in New York on April 7 on the charge of practising medicine without a license was held for trial by Magistrate Kernochan in the Yorkville Court on June 19. Magistrate Kernochan thus concurs in the opinion recently given by Magistrate Freschi in the Cole case that such practice is a violation of the law.

A "Sane Fourth".—The Department of Health of New York announces that because of the small amount of tetanus antitoxin which was used last Fourth of July it will be unnecessary to prepare an additional stock this year. Enough is on hand to treat any cases requiring antitoxin, and Commissioner Lederle has asked that in cases of injury the department be immediately notified.

Dr. William Osler, Regius Professor of Medicine at Oxford University, England, and formerly Professor of Medicine at Johns Hopkins University, Baltimore, was among the recipients of coronation honors recently, the rank of baronet being conferred upon him. Dr. Osler went to England from Baltimore in 1904.

The President on Patent Medicines.—In a message sent to Congress on June 21 President Taft recommends the enactment of an amendment to the pure food law so as to prevent the shipment

in interstate commerce and the manufacture and sale in Territories of what he aptly characterizes as "worthless nostrums labeled with misstatements of fact as to their physiological action." The President says: "An evil which menaces the general health of the people strikes at the life of the nation. In my opinion, the sale of dangerously adulterated drugs or the sale of drugs under knowingly false claims as to their effect in disease constitutes such an evil and warrants me in calling the matter to the attention of Congress." In a recent decision the Supreme Court held that the present law does not cover the knowingly false labeling of patent medicines as to curative effect, and that inquiry under this statute does not by its terms extend in any case to the inefficacy of preparations to work the cures claimed for them on the labels. The President is impressed with the desirability of immediate action on a law which will prevent the perpetration of such fraud.

Dr. William Henry Howell, formerly dean of the Johns Hopkins Medical School, received the honorary degree of doctor of science from Yale University at the commencement exercises on June 21.

Yale Medical School.—In his annual report on the University recently, President Hadley of Yale devoted some attention to the needs of the Yale Medical School, declaring that this was the point at which a large endowment was most immediately needed. An endowment of $2,000,000 for the school is in his opinion imperatively necessary if Yale is to continue to take part in the work of general medical education. Without such an endowment it cannot be a place for the education of physicians; with it it can give medical training of the very best kind. The Yale Medical School will celebrate its hundredth anniversary in 1913.

Sea Breeze, Junior.—As for several years past, the institution known as Junior Sea Breeze was opened on June 19 on the grounds of the Rockefeller Institute overlooking the East River, New York. The institution has accommodations for sixty babies, and also a dispensary and a shelter for mothers and children, where talks on the proper care of infants are given. The work will be continued until September 1, funds for carrying it on being supplied by Mr. John D. Rockefeller.

Marine-Hospital Service.—The Senate on June 20 passed the bill increasing the salaries of the officers of the United States Public Health and Marine-Hospital Service, and otherwise increasing the efficiency of the corps.

Cholera in Naples.—The Italian steamship *Europa*, which arrived in New York on June 14 from Genoa and Naples, brought into port a steerage passenger ill with cholera, while the North German Lloyd liner *Berlin*, which arrived the day before, reported the death of one of the steerage passengers at sea from the same disease. In both cases the diagnosis was confirmed by bacteriological examination. The steerage passengers on both ships were detained at Quarantine for observation. Surgeon-General Wyman of the Public Health and Marine-Hospital Service has been notified by Surgeon King, at Naples, of the outbreak of cholera in that city and of the precautions which are being taken to enforce the health requirements with respect to emigrants from that port. Surgeon J. M. Eager has been ordered to Naples to assist Dr. King.

The British Census.—Further census returns show that the excess of females over males in Great Britain amounts to 1,178,317. This would be decreased, however, if the soldiers and sailors serving abroad were included in the census.

Dr. Samuel B. Lyon, superintendent of Bloomingdale Asylum, New York, for the past fifteen years, has resigned his position, and on July 1 will become superintendent emeritus.

Obituary Notes.— Dr. Isaac W. Blackburn of Washington, a graduate of the Medical Department of the University of Pennsylvania in 1882, professor of morbid anatomy in the University of Georgetown, District of Columbia, and chief pathologist to the Government Hospital for the Insane, Washington, died at his home on June 19, aged 60 years.

Dr. John Law of Denver, Col., a graduate of the Northwestern University School of Medicine, Chicago, in 1868, died at his home on May 28, aged sixty-seven years.

Dr. Benjamin Perrine Marsh of Bloomington, Ill., a graduate of the Hahnemann Medical College and Hospital of Chicago in 1875, died at his home after several weeks' illness on May 30, aged seventy years.

Dr. Robert Lee O'Brien of Akron, Col., a graduate of the Baltimore University School of Medicine, Maryland, in 1904, secretary of the Eastern Colorado Medical Association, and county physician, was killed in an automobile accident on May 30, at the age of thirty-five years.

Dr. David W. Collins of Pueblo, Col., a graduate of the medical department of the University of Louisville, Kentucky, in 1882, died at his home on May 25, after a long illness, aged fifty-seven years.

Dr. Albert S. Green of Rockford, Ill., a graduate of the Northwestern University Medical School, Chicago, in 1878, and a member of the American Medical Association and the Wisconsin State and Illinois State and Winnebago County Medical Societies, died at his home on June 1, aged fifty-eight years.

Dr. J. E. Jewell of Portland, Ore., a graduate of the College of Physicians and Surgeons of Baltimore, Md., in 1881, died suddenly on May 24.

Dr. John W. Watenpaugh of Weaverville, Cal., a graduate of the Hahnemann Medical College of the Pacific Coast, San Francisco, in 1901, died suddenly in St. Caroline Hospital, Redding, of typhoid fever, on May 26, aged thirty-five years.

Dr. George D. Miller of Boydsville, Mo., a graduate of the Missouri Medical College, St. Louis, in 1885, died at his home from the effects of an overdose of morphine, on June 5, aged 60 years.

Dr. Horace B. Cole of Sedalia, Mo., a graduate of the Baltimore Medical College in 1893, and a member of the staff of the Maywood Hospital, died at home of typhoid fever, on June 3, aged 49 years.

Dr. Frederick Adam Powell of Sioux City, Iowa, a graduate of the Jefferson Medical College of Philadelphia in 1891, attending oculist to St. Joseph's Hospital, and a member of the American Medical Association, the Iowa State and Woodbury County Medical Societies, and the Sioux Valley Medical Association, died at his home, on June 7, aged 44 years.

Dr. Norman Rhinehart Hook of Oskaloosa, Iowa, a graduate of the College of Physicians and Surgeons of Keokuk, Iowa, in 1874, died suddenly of heart disease, on June 3, aged 68 years.

Dr. John Franklin Fargo of Los Angeles, Cal., a graduate of the Hahnemann Medical College and

Hospital of Chicago in 1881, died at his home after a short illness, on June 6, aged 76 years.

Dr. Solomon Sargeant Stearns of Washington, D. C., a graduate of the Medical Department of the University of Georgetown, D. C., in 1868, died suddenly at his home, on May 31, aged 72 years.

Dr. William P. Brierly of Albany, N. Y., a graduate of the Albany Medical College in 1886, and a member of the New York State and Albany County Medical Societies, was struck by a trolley car on the Schenectady turnpike and instantly killed, on June 22.

Dr. Madana F. DeHart, the first woman physician of Jersey City, N. J., a graduate of the New York Medical College and Hospital for Women in 1868, died at her home in Mount Freedom, N. J., on June 22, after a short illness.

Dr. George W. Bailey of Elizabeth, N. J., a graduate of the Hahnemann Medical College of Philadelphia in 1862, a surgeon in the United States Army during the Civil War, and a trustee of the Presbyterian Hospital of Philadelphia, died at his home on June 21, aged 71 years.

Dr. Carl H. Lellmann of New York, a graduate of the University of Göttingen, Germany, in 1854, and a member of the New York State and County Medical Societies, died in Karlsruhe, Germany, on June 21, aged 80 years.

Correspondence.

OUR LONDON LETTER.

(From our Regular Correspondent.)

THE INSURANCE BILL—FRIENDLY SOCIETIES ON THE BILL AND ON DOCTORS—CONFERENCE ON DESTITUTION; HEALTH SECTION—TUBERCULIN AND TUBERCULSIS DISPENSARIES, THEIR DIFFERENCES—LIVERPOOL TROPICAL SCHOOL—OBITUARY.

London, June 9, 1911.

The state insurance bill continues to intrude into all conversation. The friendly societies have been meeting during the week and on many points they are dissatisfied. In some speeches Mr. Lloyd George was accused of having quite deceived their leaders. In others fear was expressed that he had his eye on their reserve funds, which amount to millions, and the societies resolved in several cases to retain full control of their property—a natural resolve—for it is the accumulation of their thrift. Most of the societies are equally determined to keep, if possible, the administration of the benefits in their own hands. Some of them make a demand that they shall have the appointment of the doctors and "make rules and regulations in respect to their duties." One speaker was applauded for denying that the societies had ever made hard bargains with the doctors and asserting on the contrary that they had done much to popularize the medical profession! Another went so far as to call the doctors "avaricious" and compared them to "vultures after carrion." The key to this abuse is probably furnished by the assertion of another speaker that the doctors "were out for all they could get and whatever they did get would come out of the workers' pockets." The meetings as a whole seem disposed to accept the scheme on condition that the government consent to some important amendments which they emphatically insist on. They are therefore engaged in careful examination of the numerous clauses affecting them with a view of formulating their demands. No doubt Mr. Lloyd George will give way on some points rather than risk the votes of the labor and trade union parties. Whether such a fear will affect him with regard to the medical profession is doubtful.

The national conference on destitution has been held and has attracted more attention than usual, the five sections being numerously attended each day. Sir Clifford Allbutt was president of the Public Health Section and in his address remarked as to overlapping, which was likely to occur. It was well to cherish variety in the administration of charitable agencies in order to avoid falling into the monotonies of rigid officialism. The hospital, he said, was but a patch on disease; charity organization a patch on pauperism: the refuge a cloak for the ineffectual; state subsidies a patch on destitution. Could they expect much more in the long run from reformatories than that they would become patches on grown up violence, shuffling, plausibility, and depravity? Some trustworthy statistics as to births and deaths had been accumulated but it was more important to gather those of invalidity, morbid incidence, and proclivity, about which mortality returns gave no data. But the state must lay no more unpaid or half-paid tasks on the unfortunate medical practitioner.

Dr. Sourfield, M. O. H. for Sheffield, read a paper advocating the compulsory notification of tuberculosis in order that steps might be taken to deal with the danger of infection. The system had been in operation in Sheffield for over seven years and no practical objection had been made. It enabled them to organize visitation of homes and workshops, provide hospital accommodation and select cases for sanatorium treatment. If tuberculin turned out as valuable as anticipated it could easily be grafted on to their scheme.

Dr. Bostock Hill, professor of hygiene at Birmingham University and M. O. H. for the county, said the object of the sanatorium was to put the patient under the best conditions and instruct him how to prevent the spread of the disease in his family or to those around him. The question of cure mostly depended on treatment at an early stage. Voluntary notification had been tried but compulsion was necessary to secure the full benefit. Buildings should not be costly but mere shelters, such as are now used for administration blocks. Funds were needed, outside the poor law, to help the families of patients in the sanatorium.

Dr. J. Niven, M. O. H. for Manchester, would have instruction given in schools on the subject of phthisis. Moreover he would have separate schools for tuberculous children.

Dr. D. J. Williamson of the Paddington and Kensington dispensary for consumption said pretty well all the tuberculous of the district came to that institution and its officials could at any time point to the spots calling for improvement. All other health factors should range round such centers.

Dr. Mearns Fraser, M. O. H. for Portsmouth, made perhaps the most important contribution to the section. Under his advice the Portsmouth town council has agreed to open a municipal tuberculin dispensary, the first health authority to do so. They felt it hopeless to rely on sanatoria, for each case sent cost £20 and the patient's family had often to be supported during his absence. But he had assured them that consumptives could be, and had been, successfully treated by attending at tuberculin dispensaries without practically interfering with their work. The importance of this he said could

not be exaggerated. In these dispensaries there was no loss of self-respect, the man continued to be independent, supporting himself and family throughout the treatment. Though as a municipal institution it was an innovation, there had been such dispensaries in London and elsewhere.

I told you last January something about the one in London. It was founded and has been worked by Dr. Carnac Wilkinson, who insists on very exacting conditions to test the value of tuberculin both in diagnosis and treatment. Many practitioners have attended his dispensary and watched his proceedings during the past few months and probably the majority have been favorably impressed. One of the most important considerations is that the system does not require the patient to give up his work and so lose his wages. Dr. Wilkinson thinks that the work does no harm provided it is not too laborious or the hours too long. The tuberculin treatment can thus be carried on without any interference with the victim's occupation and is in that a striking contrast to the sanatorium plan. So it is in regard to the cost. Again it is capable of coping with all the cases, whereas the sanatorium can only be resorted to in a small percentage.

You will observe that the tuberculin dispensary must not be confounded with those established some time ago and spoken of as tuberculosis or anti-tuberculosis dispensaries of which we have several here and I think you have also on your side. These attempt to meet infection in the homes of the victims. The anti-tuberculosis dispensary is open to all and its medical officers and nurses visit the patients and instruct them and their families on the open air treatment and the precautions to be observed to prevent the spread of infection. The contacts are, of course, examined. Cases are also selected for sending to a sanatorium, others to hospitals. Tuberculin is, I believe, employed both for diagnosis and treatment, though it is not generally credited with such curative effect as Dr. Wilkinson believes it to possess.

The meeting of the General Medical Council has passed by without exciting the slight attention it has obtained of late years. I told you last week of its report on the insurance scheme, which many condemn as half-hearted. Its only other action talked of is the condemnation of the registered practitioners who lent their support to Sandow's Institute. It is a roundabout way of dealing with quackery but the only one open to the council. Sandow suffers nothing but official medical repudiation of the claims to cure which he advertises and the people will pay no attention to the condemnation unless to call it professional jealousy. Counsel for the accused did not hesitate to supply this key to the proceedings though he probably would not dare to do so could a parallel case occur in his own profession.

Professor Newstead of the Liverpool Tropical School was to embark yesterday for Nyanaland to study the tsetse fly. He will arrive in advance of the expedition and assist local authorities in the choice of a spot for establishing a permanent laboratory. He lately issued "The Tsetse Fly Pest" dealing chiefly with the anatomy of the males. Last year he discovered four species not previously described. One of these is thought to be carrying a disease of cattle in German East Africa which the observers there think is allied to sleeping sickness in man. On Wednesday evening a banquet was given by the Liverpool Tropical School to Professor Newstead and to Professors Todd and Wolback, who have just returned from an expedition to the Gambia and Senegal.

Dr. Alexander Bruce, F. R. S. E., of Edinburgh has died at the age of 56. After studying on the Continent as well as in Edinburgh he took his M.D. at the last named with first class honors in 1879. He was physician to the Royal Infirmary and held other important appointments. His works on the brain and spinal cord will be well known to you as well as many of his valuable papers on neurological subjects at different societies and in the *Review of Neurology and Psychiatry* which he edited.

OUR BERLIN LETTER.

(From Our Regular Correspondent.)

PREVALENCE OF SCABIES—IMPORTANCE OF SOCIAL MEASURES IN FIGHTING DISEASE—SYPHILIS IN RABBITS—CHRONIC CASES IN HOSPITALS.

BERLIN, April 15, 1911.

AT the first meeting of the Society of Social Medicine, Hygiene, and Medical Statistics, for the year 1911, an address of quite extraordinary interest was delivered by A. Gottstein. The subject was the effect of therapy upon epidemics, together with a contribution to the epidemiology of scabies. The speaker stated that the first impression one obtained by a consideration of Ehrlich's new remedy was the thought that at last the spread of syphilis would greatly diminish. That this result is more than questionable may be noted on comparison with scabies. For exactly in this disease are to be noted the two conditions necessary for the annihiliation of disease, namely, the communicability from individual to individual without the intermediation of an animal host and without any independent existence outside of the human body, and also the use for decades of rapid and certain methods of cure. Statistics teach, however, that in the public hospitals of Germany, from 1886 to 1901, reckoning by periods of three years each, the number of cases of scabies per thousand of all diseases were as follows: 43.3 43.7, 71.4, 60.5, and 35.8. There was therefore no marked reduction in the incidence of scabies. That this disease is widespread is noted by an examination of the statistics of admissions to all hospitals in Prussia. While pulmonary tuberculosis takes first rank with 60 per cent., scabies comes second with 42 per cent. Although for the past 50 years the world has possessed rapid and certain as well as cheap remedies for this disease, the figures indicating its prevalence do not show any pronounced diminution. On the other hand, in the Army, from 1882 to 1908, as the result of a systematic medical supervision, the cases of scabies have diminished from 13.1 per thousand to 7.2 and even to 3.3 as recently recorded. Among the laboring classes the results of uncleanliness and indolence are noted among the immigrants from Russia, Galicia, and Italy. Even in the better circles, with all the facilities for unlimited medical advice and care, the prevalence of scabies is an extraordinary one. At the local health insurance office at Leipsic, among 100,000 males, there presented themselves for treatment 118 affected with syphilis and 99 with scabies. Ignorance and indolence are therefore two factors that render illusory the most advanced individual treatment in the eradication of disease. In every ailment, in addition to the individual care, there is the social factor. The teacher and parent, next to the laboratory worker, are indispensable aids.

March 29, 1911, Uhlenhuth and Mulzer presented before the medical society an interesting address upon experimental inoculation syphilis in rabbits. Serum obtained from human roseola spots was injected by means of a fine capillary tube into the testes of rabbits. After passage through 16 animals a very powerful virus was obtained. The period of incubation was four weeks. In very many cases the results were positive. Rabbit syphilis occurs in three different forms: 1. Primary syphilitic erosions and ulcerations with spirochetes. 2. Chronic diffuse or circumscribed inflammation of the testicles. 3. Diffuse or circumscribed periorchitis. The Wassermann reaction gives no definite information, for it may be present in normal animals. The later manifestations of syphilis in the rabbit are keratitis, anal vegetations, general cachexia, gumma of the cartilaginous septum, caudal tumors, cutaneous ulcers, chiefly of the lobule of the ear, and of the chin and eyebrow, small tumors in the eyelids, conjunctivitis with abundant secretion, paronychia with loss of the nails. General glandular enlargement was not observed. But local enlargement of the lymph nodes was observed, with the presence of spirochetes. These were also obtained from the circulating blood. Rabbit syphilis can be communicated to monkeys, guinea-pigs, and goats. Atoxyl and salvarsan proved to be good remedies. An immunity was not demonstrable. Healthy offspring of diseased animals were observed.

Hospital physicians in Berlin have for many years endeavored to relieve the hospitals of the care of chronic cases, chiefly of tuberculosis. The necessity of this relief is noted in an examination of the last report by Stadlmann of the medical division of the Friedrichshain Hospital. The number of cases of tuberculosis has increased from 450 in the year 1909 to 554 in 1910. Most of these cases are incurable and remain in the hospital many months until their death. In addition, the hospital harbors alcoholics with delirium tremens, and cases of cirrhosis of the liver, nephritis, and arteriosclerosis. All of these patients would do better in homes and special hospitals, thus affording more room for acute cases, the need for which is most pressing in time of epidemics.

OUR VIENNA LETTER.

(From Our Regular Correspondent.)

SUNLIGHT IN THE TREATMENT OF TUBERCULOSIS— PHYSIOLOGICAL EFFECTS OF HIGH ALTITUDES— LABYRINTHINE SUPPURATIONS — BIOLOGICAL STUDIES ON THE OVARIES.

VIENNA, May 1, 1911.

THE solar treatment of surgical tuberculosis was recently made a special study by Max Jerusalem. The fundamental principles of this treatment are divided into two catagories: the one operative, the other conservative. The former is more adapted for adults, the latter for children. The operative treatment when carried out in children suggests particularly palliative measures; tapping and injection of iodoformglycerin, and the removal of circumscribed foci. Extrarticular foci indicate operation, for the tuberculous process may invade the joint. Not only at the operation but also in the after-treatment strict asepsis must be observed in order to prevent a mixed infection. The conservative treatment consists in the fixation of the diseased member; the treatment by means of passive hyperemia is of advantage in the case of open fistulous processes, but has no value in the case of fungous growths. The iodine and soft soap method of treatment is well known. Favorable results have been reported from the use of the *x*-rays; but tuberculin has given varying results, in some cases having made the condition worse. Bismuth paste has demonstrated its value in fistulous tracts. Neither the operative nor the conservative methods of treatment have been entirely satisfactory. The solar treatment has been carried out by Rollier in Lucerne. He has applied conservative methods. Closed tuberculous foci have not been opened, only the infected cases have been widely opened and the wounds exposed to the direct action of the sun's rays. The patients are exposed outdoors during the day, and in some instances also during the night. The diseased area has been exposed to the sunlight, as the result of which treatment pain has disappeared, appetite has improved, tuberculous foci have cleared up, and the mobility of the joints has been restored. The curative factors in the Lucerne treatment are sunlight, abundant diet, and fresh air. Ulcers heal not only at the periphery but also in the center, so that the contraction of scars rarely occurs. The area exposed to the sun's rays becomes deeply pigmented. Glandular tuberculosis reacts to the sunlight less favorably than does tuberculosis of the bones. The solar treatment is favored by a dry atmosphere, which explains the advantage of high altitudes over the seashore in the treatment of tuberculosis.

The physiological action of high altitudes of various regions and of various degrees has been investigated by Arnold Durig, who has found that the composition of the air, particularly its oxygen and carbon dioxide content is practically constant at different localities, showing variations only to the extent of hundredths of a per cent. Bacteria, even those of pneumonia and of septic angina are found at the highest altitudes. The bodily metabolism in conditions of absolute rest is influenced neither by temperature, light, humidity, nor by the velocity of the winds. The change in the atmospheric pressure at high altitudes is a weighty factor. The belief that the red blood corpuscles increase in number at high altitudes has not been confirmed; their number varies, however, considerably during the day. An increase in hemoglobin and an increase in the oxygen-binding capacity has not been proved, nor does the iron-content of the blood show a constant figure. The frequency of the pulse rises at an altitude of about 4,500 meters, and a descent to an altitude of 1,500 meters causes a diminution in the pulse to the extent of 40 beats. A prolonged residence at high altitudes causes a decrease in the initial acceleration of the pulse. In the case of a normal heart there is no substantial change in the pulse-form, nor in the blood pressure, while cutaneous cyanosis is to be regarded rather as the result of the influence of external temperature and of diminished oxidation. Muscular exercise causes a change in the respiration. At high altitudes there is a diminution in the carbondioxide pressure of the blood, so that a slighter influence than usual is exerted upon the respiratory center, as a result of which the respiratory rate is diminished, and in consequence the carbondioxide content of the blood increases with an increased stimulation of the respiratory center and an increase in the pulse-rate. According to the degree of work and the altitude, the oxygen-need varies between 280 and 2,800 cubic centimeters. At high altitudes

there occurs a storage of nitrogen in the form of protein. This cannot be circulating albumin, for on descent to lower altitudes there is no immediate increased albuminous excretion. Some of the unpleasant effects of high altitudes are insomnia and headache. To a certain degree high altitudes have a stimulating effect, beyond which the influence is a harmful one. Chlorosis is not cured alone by residence at a high altitude.

New observations on labyrinthine suppuration have been reported by Prof. Adam Politzer before the Practitioners' Society. Eighteen fatal cases of otitic complications that had been carefully studied during life, showed at autopsy in ten cases marked anatomical changes in the labyrinth, while in eight cases, in spite of profound changes in the middle ear no demonstrable changes in the labyrinth were found. The following lesions were found: 1. Perforation of both fenestra of the labyrinth, with penetration of the pus into the interior of the labyrinth. 2. Fistulous openings in the semicircular canals and on the inner wall of the tympanum. 3. Destruction of the epithelial framework of the labyrinth, and of the organ of Corti. 4. Disappearance of the bony wall of the labyrinth and of the modiolus of the cochlea with perforation into the inner auditory canal. 5. Inflammatory changes in the latter and suppurative infiltration of the auditory nerve. 6. Connective tissue and osseous neoplastic formation in the cochlea as the result of an old inflammatory process that had run its course in the labyrinth. As otitic complications with lethal outcome there were evident meningitis, extradural abscess, cerebellar abscess, temperosphnoidal abscess, and sinus throbbosis. According to the statistics of Politzer's clinic the fatal outcome in more than half of the cases was due to a meningitis resulting from an infection by way of the labyrinth. Politzer has shown that this complication proceeds preferably through the cochlea. He rejects those operative methods that are confined to a breaking down of the semicircular canals and an opening up of the vestibule, and lays down the postulate that the operative clearing out of the cochlea, and, therefore, the eradication of the dangerous focus of suppuration in the labyrinth, are necessary. In the presence of extradural abscess and of intracranial complications, the method of Jansen-Neumann is indicated, namely, the removal of the posterior pyramidal wall and the opening up of the labyrinth from the median side. On the other hand, in the case of labyrinthine suppurations without cerebral complications, Politzer recommends the removal of the wall of the promontory and the wide opening up of the vestibule and cochlea, which are to be thoroughly cleared out. The advantage of this method is the impossibility thereby of wounding the facial nerve.

Biological studies of the ovaries have been made by J. Neumann and E. Herrmann, who have come to the following conclusions: The lipoid content of the blood is subject to cyclic variations in the sexually mature woman and in the bitch, which variations consist in a diminution during the menstrual perod and during the period of rut. During and after the climacteric there is lipoidemia. Castration in the human being, dog, and rabbit causes the same condition. In the rabbit treatment of the ovaries with the *x*-rays causes lipoidemia. This is also associated with normal pregnancy, from which one may conclude that during the latter there is a gradual functional alteration, in other words, there is a functional disappearance of the follicular apparatus of the ovaries.

In the blood of pregnant animals there have been found crystals that possess the following properties: Even in small quantities of blood an abundance of these crystals may be obtained. They are long, fine needles that taper like hairs, are easily bent, and give one the erroneous impression of plant threads. Upon pressure being applied to the cover-glass they break without a smooth line of fracture. In polarized light they are illumined between crossed Nicol prisms. The isolated crystals were recrystallized from acetone, and gave the reaction of cholestrinester, and showed a melting-point of 77° C., which is identical with that of cholesterin-palmitinacidester. This cholesterinester was observed in normal serum by von Boudet in 1833, and von Hüsthle in 1895 The blood of pregnant animals apparently contains an increase of this substance.

Progress of Medical Science.

Boston Medical and Surgical Journal.

June 15, 1911.

Obstetrics in General Practice. A. Worcester.
Hexamethylenamine as a Possible Preventive of Pneumococcus Empyema. F. C. Shattuck.
"Fibrositis" as a Cause of Chronic Hypertrophic Spondylitis and Possibly with a Heretofore Undescribed Sign in Intestinal Auto-Intoxication. N. S. Yawger.
The Treatment of Gastric Hyperacidity with Hydrogen Peroxide. G. W. Hall.
A Case of Vertigo Cured by Treatment of the Eustachian Tube. E. M. Holmes.
A Case of Nerve Deafness Due to the Toxemia of Diabetes. W. H. Merrill.
Lateral Deviations of the External Nose. A. Coolidge, Jr.
Plaster Casting from Life to Show External Deformities of the Nose Before and After Correction. I. D. Kerr.

Obstetrics in General Practice.—A. Worcester reviews a series of five hundred obstetric cases occurring in his practice in the course of fifteen years. He believes that the Crédé method of expressing the placenta is the cause of a large percentage of postpartum hemorrhages. The author entrusts the management of the first stage of labor almost always to a nurse. He uses a mixture of chloroform and ethyl bromide to dull the suffering from second stage pains. To help on the progress of the delivery he has often dilated the cervix, flexed the baby's head, and rotated it into a more favorable position. Two cases of death from pulmonary embolism are reported in addition to two reported in a former series, in all four deaths in a series of 1,000 cases. These fatalities occurred in the course of thrombosis of the iliac veins, the patients having been allowed to sit up too soon.

Hexamethylenamine as a Possible Preventive of Pneumococcus Empyema.—F. C. Shattuck has found that the administration of this drug has no influence in preventing the incidence of empyema in the course of pneumonia.

Fibrositis as a Cause of Chronic Hypertrophic Spondylitis.—N. S. Yawger believes that chronic hypertrophic spondylitis is often but the spinal localization of a very common general condition, the result of intestinal autointoxication.

Hydrogen-Peroxide in Gastric Hyperacidity.—G. W. Hall has found that hydrogen peroxide diminishes the amount of hydrochloric acid in the stomach. Its administration to patients with hyperchlorhydria greatly relieves their symptoms and causes a gain in weight. It does not appear to benefit cases with active ulcer. This method of treatment is a useful addition to the methods already in use.

Vertigo.—E. M. Holmes reports a case of vertigo cured by treatment of the Eustachian tube.

Nerve Deafness in Diabetes.—W. H. Merrill reports

a case which illustrates the fact that the acetonemia of diabetes, in common with the toxemia of syphilis, influenza, malaria, etc., can easily produce a neuritis of the eighth nerve as of others which are rather frequently involved.

Lateral Deviations of the External Nose.—A. Coolidge discusses the various types of this condition and the operative procedures for their relief.

Plaster Casting from Life.—I. D. Kerr describes the different methods for making plaster casts from life to show external deformities of the nose before and after correction.

New York Medical Journal.

Prescriptions Old and New. J. J. Walsh and J. P. Walsh.
Twilight Talks with the Doctor. G. F. Butler.
The Effects of Certain Chemicals on the Type of Tissue Resulting from Chronic Irritation. G. L. Rohdenburg and F. D. Bullock.
An Obscure Case of Miliary Tuberculosis (Pulmonic Type) Diagnosticated by the *X*-Ray. G. Rosenbaum.
Mortality from Venereal Diseases. H. A. Brown.
Side Lights on the Social Peril. M. Glasgow.
Foramitti's "Tubulization" Method of Nerve Suture. G. Torrance.
Rupture of the Intestine from a Blow on the Abdomen. H. A. Royster.
Amygdalotomy or Amygdalectomy. M. Lubman.

Prescriptions Old and New.—J. J. and J. P. Walsh describe one of the oldest prescriptions extant, namely, an inscribed stone in the Egyptological department of the Metropolitan Museum of Art, New York. The date of the prescription was probably not far distant from that of the Ebers papyrus. The prescription called for a remedy to be used as a fumigation, the important ingredient of which was some form of precious green stone. The authors describe some of the favorite prescriptions of Galen, which for about fifteen centuries constituted the model after which most prescriptions were written.

Twilight Talks.—G. F. Butler discusses the futility of contentions which he believes frequently mar the harmony of the medical profession.

Type of Tissue Resulting from Chemical Irritation.—G. L. Rohdenburg and F. D. Bullock performed a series of experiments to determine if there are substances in the body, the result of metabolic processes, which stimulate cell division. They found that substances of which xanthine is a type produced marked proliferation of cells, more so than the lipoids. It is suggested that perhaps other products of protein metabolism, more especially the end or intermediate products, may have a similar and perhaps more profound effect, not alone on connective tissue, as xanthine apparently has, but also on epithelial structures.

X-Ray Diagnosis of Pulmonary Tuberculosis.—G. Rosenbaum reports a case which illustrates the inestimable value of the *x*-ray in cases in which the physical signs are indefinite, frequently showing only a moderate bronchitis.

Mortality from Venereal Diseases.—H. A. Brown notes the fact that the actual number of reported deaths from venereal diseases is comparatively small. The great majority of these deaths are due to syphilis. Nearly fifty-three per cent. of the deaths occur in children under one year.

The Social Peril.—M. Glasgow quotes the report of the Chicago Vice Commission which states that "prostitution can be suppressed by persistent efforts through a long period of years, and that constant and persistent repression must be the immediate method, absolute annihilation the ultimate goal."

Nerve Suture.—G. Torrance reports a case of successful suture of the musculospiral nerve. He utilized Foramitti's "tubulization" method, by means of which the nerve ends are sutured in a tube of absorbable material such as a specially prepared vein or artery taken from a freshly slaughtered calf.

Rupture of Intestine.—H. A. Royster reports a case of rupture of the intestine resulting from a blow on the abdomen.

Tonsillotomy or Tonsillectomy.—M. Lubman advocates the total enucleation of the tonsils when the tonicity of their epithelium is lost.

Journal of the American Medical Association.

The Effect of Injections of Indol and Tyrosin in Experimental Animals. P. G. Woolley and L. H. Newburgh.
Conjugal Tubes Dorsalis. A. A. Fshner.
The Gastric Weak Line in Wounds of the Abdominal Wall. R. T. Morris.
Chronic Lead Poisoning: Report of a Case. C. H. Snover.
A New Method of Diagnosis of Acute Intestinal Obstruction by the Stomach Tube. G. H. Watson.
Trephining for Apoplexy. J. D. Milligan.
A Simple Technique for Salvarsan Injection. M. A. Reasoner.

Diet in Acute Infectious Diseases.—F. S. Meara criticizes the exclusive use of milk in infectious diseases and points out that to meet the caloric needs in fever of the ordinary individual, one would have to administer over a gallon of milk, which would contain almost twice as much protein as necessary. There are four problems entering into the feeding in acute infectious diseases: gastrointestinal disorders, pyrexia, toxemia, and starvation. The last of these it is the plea of the author to prevent. Fat and carbohydrate, especially the latter, are sparers of body proteids, and when enough of these two are taken nitrogen equilibrium has been obtained.

Gastric and Duodenal Adhesions.—G. E. Pfahler concludes that gall-gladder disease is liable to give rise to adhesions, which cause a definite displacement of the stomach and duodenum which is recognizable by the *x*-rays. The evidence of adhesions is best obtained fluoroscopically in the upright position, in which the errors of pressure must be eliminated, but plates should also be made in every case for record and for more detailed study.

Treatment of Arthritis Deformans.—P. W. Nathan has found in the treatment of the metabolic form of osteoarthritis that continuous administration of thymus extract sooner or later led to definite improvement. It is only when it is taken for months that the joint disability begins to disappear and in some of his patients he has been able to demonstrate the action of the thymus, since when it was discontinued the symptoms began to reappear. The dosage of thymus extract was five grains three times a day after meals.

Abdominal Symptoms in Thoracic Disease.—A. R. Edwards states that pneumonia, pleurisy, and pericarditis at their very onset may present absolutely no symptom other than the abdominal findings. These phenomena of invasion may completely resemble appendicitis, peritonitis, even the collapse of perforation. Diagnostic errors and unnecessary operations may be unavoidable.

Medical Classics.—F. H. Garrison describes the collection of medical classics in the library of the Surgeon-General's office at Washington.

Rupture of Umbilical Cord.—M. J. Press reports a case of rupture of the umbilical cord within the abdominal walls of an infant at birth, treated successfully by compression.

Laryngopharyngeal Lipoma.—E. L. Kenyon reports

the removal of a large lipoma embarrassing the functions of respiration, swallowing, etc., but giving no evidence of its presence in the appearance of the outer surface of the neck.

Salvarsan in Pellagra.—H. P. Cole and G. J. Winthrop in reviewing twenty-one cases of pellagra treated with salvarsan state that this drug offers no better results than other methods of treatment.

Glass Tube in Male Urethra.—N. Evans reports his success in removing a piece of glass tubing 3/16 of an inch in diameter and 5 inches long from the male urethra.

Scarlet Fever.—L. Hektoen and G. H. Weaver, in reporting their results in the feeding of monkeys with milk containing secretions from the throats of scarlet fever patients, state that there was no conclusive evidence that the monkeys contracted scarlet fever.

Artificial Cultivation of Tissues.—M. R. and W. H. Lewis find that this can be effected in various salt solutions as well as in plasma.

Indol and Tyrosin.—P. G. Woolley and L. H. Newburgh found that after the injection of these substances into rabbits the medullas of the adrenals were hyperplastic and apparently hypertrophic, and that the evidences of chromaffin activity increased in proportion to the number of injections, until in the last of the series the medullas showed a volume three times the normal, while the cortices were not increased. The suggestion is made that such hyperactivity of chromaffin and like substances may be a cause, if long continued, of diabetes on account of a change in the chromaffin-pancreas equilibrium.

Conjugal Tabes Dorsalis.—By A. A. Eshner. See MEDICAL RECORD, Volume 79, page 1073.

Abdominal Wounds.—By R. T. Morris. See MEDICAL RECORD, Volume 79, page 1023.

Chronic Lead Poisoning.—C. H. Snover reports a case of this condition occurring in a girl employed in a milk condensery sealing cans.

Diagnosis of Intestinal Obstruction.—H. G. Watson suggests, as an aid to diagnosis in this condition, that the stomach tube be passed from hour to hour, and the contents carefully examined. If they are of a dark brown color with a fecal odor, ruling out peritonitis and other acute conditions, then a definite diagnosis of acute intestinal obstruction can be made and immediate operation advised.

Trephining for Apoplexy.—J. G. Milligan advocates operative interference in cases of hemorrhage of the brain. After the first seventy-two hours, the patient having survived the shock, he is in better condition for operation than is the usual case of cerebral traumatism.

Salvarsan.—M. A. Reasoner describes a simple technique for the intravenous injection of salvarsan.

The Progress of Dermatology Since Hunter's Time. J. H. Sequeira.
The Rôle of Fat in the Etiology and Progress of Cancer. Sir George T. Beatson.
The Position of the Present Reform Movement in Anesthetics. F. W. Hewitt.
The Use of Explosives in Coal Mining and Their Effect upon Miners. Sir Thomas Oliver.
Ten Cases of Operation for Ménière's Disease (Aural Vertigo). R. Lake.
Twenty-two Consecutive Cases of Extrauterine Pregnancy Successfully Treated by Operation. J. A. Kynoch.
Prophylactic Inoculation Against Hay Fever. L. Noon.
A Case of Suppurative Arthritis of Knee-joint, due to Influenza Bacillus, occurring in a Baby Aged Six Months. E. T. Fraser.
A Case of Acute Phthisis Following Typhoid Fever. W. Scarisbrick.
Endemic Tetany in the Gilgit Valley. R. McCarrison.

Progress of Dermatology.—J. H. Sequeira describes the progress of dermatology since Hunter's time. The first years of the nineteenth century really marked the beginning of the scientific study of diseases of the skin.

Rôle of Fat in the Etiology of Cancer.—Sir George T. Beatson believes that fat plays an important part in the etiology and progress of cancer. Duncan has observed that there is a decided difference in human fat before and after puberty, the low percentage of 44.477 of non-saturated fatty acids between nine and eleven years of age being replaced by the high one of 60.88 from sixteen to nineteen years. Further, a similar increase takes place in the fat of cancer patients, the percentage rising from 62.1 in health to 72.62 in that disease.

Reform Movement in Anesthetics.—F. W. Hewitt states that when anesthetics are administered only by qualified persons it will be far easier than it is at present to improve the conditions under which anesthesia is conducted.

Explosives in Coal Mining.—Sir Thomas Oliver states that miners suffer by inhaling the fumes given off after detonation of cartridges of the higher explosives. Occasionally miners are found in the pit in a state of collapse, of complete powerlessness, or of unconsciousness, and when brought to bank they frequently vomit, thereby obtaining relief. Taken home, placed in bed, and surrounded by warmth these men gradually recover, and in a day or two, although apparently shaken, they are found back at work again. By some men, owing, it is supposed, to the nitrous compounds present in the cartridges, complaint is made of throbbing headache and rapid action of the heart.

Operation for Ménière's Disease.—R. Lake states that relief may be promised with certainty in those cases of aural vertigo, which must otherwise render life a burden to the sufferer, by an operation which in itself has no risk to life.

Extrauterine Pregnancy.—J. A. Kynoch reports twenty-two consecutive cases of this condition successfully treated by operation.

Prophylactic Inoculation Against Hay-Fever.—L. Noon has found as the result of experiments with pollen extracts prepared according to Dunbar's method that the sensibility of hay fever patients may be decreased by properly directed dosage at least a hundredfold, while excessive or too frequent inoculations only serve to increase the sensibility.

Influenzal Arthritis.—E. T. Fraser reports a case of suppurative arthritis in the knee-joint in a baby aged six months. Pfeiffer's bacillus was isolated from the pus.

Acute Phthisis Following Typhoid Fever.—W. Scarisbrick reports a case of this condition.

Endemic Tetany in the Gilgit Valley.—R. McCarrison states that this disease is a common one in India, having a peculiarly local distribution and corresponding more or less with the distribution of goiter.

British Medical Journal.

On Preventive Medicine: The Medicine of the Future. Sir James Barr.
The Importance of Pneumonia as a Cause of Death. F. M. Pope.
Some Features of Aortic Regurgitation in Young Subjects. J. M. Clarke.
Blood-Pressure in Mental Disorders. S. G. Longworth.
The Interpretation and Significance of Some Irregularities of the Pulse. W. E. Hume.

Preventive Medicine.—Sir James Barr states that in future medical men must point out the lines along which the nation is to be improved, by encouraging the multiplication of the fit, and controlling the increase of the unfit. Tuberculosis is one of Nature's methods of getting rid of the unfit; nevertheless this disease is to be combatted, for, even if it disposes of the weaklings, it inflicts permanent injury on the survivors, and carries off many an individual who would be a worthy citizen in a better environment.

Pneumonia as a Cause of Death.—F. M. Pope notes that pneumonia stands alone (or only with cancer) in its steady increase. Other respiratory diseases which seem

to be subject to the same conditions have not followed a similar course.

Aortic Regurgitation in Young Subjects.—J. M. Clarke states that aortic regurgitation in young subjects is a more serious disease and runs a shorter course than in adults. In the former pain in the precordial region is the most frequent and prominent symptom. Next in order of frequency come palpitation and dyspnea. Attacks of syncope may occur. Of the various forms of hemorrhage that are not infrequent, epistaxis is by far the most common. Great enlargement of the heart is an even more marked feature of aortic disease in children than it is in adults. With this goes pronounced dilatation of the aorta.

Blood-Pressure in Mental Disorders.—S. G. Longworth concludes that maniacal and melancholic states are not associated with any constant modification of the arterial blood-pressure, nor any marked departure in it from the normal. The same applies to other types of mental disorder with the exception of congenital states, in which the pressure tends to be low. The pressure bears some relation to the bodily tone, and increases as age advances. As melancholia is on the whole a disorder of more advanced years than mania it is associated with higher manometer readings only on this account. Sedative drugs have a slight influence in lowering blood-pressure. The manometer readings bear a fairly close relation to the sclerosis of the vessel wall.

Irregularities of the Pulse.—W. E. Hume states that an irregular pulse may have an important bearing in disease, as during an attack of pneumonia it may be the first sign of a fatal termination. An irregular pulse may be a family peculiarity, as in an instance cited in which all the sons of a family shared with the father a cardiac irregularity due to ventricular extra-systoles. A pulse may appear quite regular to the palpating finger, but the heart may be grossly irregular. This is observed in certain cases of heart block. The factors which govern the normal beat of the heart are stimulus formation, excitability, contractility, conductivity, and tonicity. In a normal heart these five properties of heart muscle fibers are interdependent, but in pathological conditions they may be affected independently of one another.

Berliner klinische Wochenschrift.

June 5, 1911.

Statistics of the Carbolic Acid Treatment of Tetanus.—Prof. Baccelli analyzes the reports of 190 cases of tetanus treated by his method. These are grouped under four classes, viz.: mild, medium, severe, and fulminating. In order to characterize cases properly from this viewpoint, the author makes use of the length of the incubation period (the shorter the period the graver the prognosis); the frequency, severity, diffusion, and duration of the paroxysms: the temperature; the age of the patient, and the individual resistance to the disease. Leaving out the mild and medium cases, which have a tendency to spontaneous recovery, the figures show that there were ninety-two cases of severe tetanus which were treated with a combination of the author's method and serotherapy. Of this large number but two patients died, a mortality of but 2.12 per cent. There were thirty-eight cases of very severe tetanus. Of this number some are rejected because the dosage was not high enough for the author's standard. Of twenty-seven cases in which the reporters injected the quantities of phenol recommended by the author, twenty-two recovered, a mortality of 18.5 per cent. In fifteen other cases of severe tetanus, in which the course could be described as fulminating, the results of treatment were practically negative (although there was a single recovery following an intraspinous injection). The author claims, however, that the doses of phenol injected were far too small. The combined mortality for the 190 cases was 17.36 per cent. The material from which these cases come is almost wholly Italian, although the author's method has been tested in other countries. The method has not undergone any notable modifications since its original introduction and is to be found in any standard work on surgery.

Rare Case of Anosmia.—Safranek sums up his case as follows: A girl aged fourteen years, with an acquired leucoderma, began to lose her sense of smell, which at the end of two years was entirely absent. The condition was bilateral and sense of taste for aromatic substances was also lost. Rhinological and neurological examination failed to reveal the nature of the disorder. Hysteria could be excluded as could also local or central organic disease. The author found two similar cases in the literature in which there was a suspicion that the association of anosmia and absence of cutaneous pigment (leucoderma) was not a coincidence. Such an association seems, however, to have escaped the attention of dermatologists.

Anesthesia in Obstetrics.—Strassmann concludes his study with a consideration of the scopolamine-morphine narcosis and analogous procedures. The number of recorded cases in which scopolamine and morphine have been given combined in various proportions is now very large, and the indications and conclusions naturally differ in different clinics. The author's personal experience is as follows: The women fell asleep and the physiological action of the scopolamine was in evidence. Some women, however, showed excitement. Pain was not fully abolished, and the patients cried out somewhat, but in from 60 to 80 per cent. of cases there was no recollection of pain. Scopolamine may be found in the breast milk until the third day. The action of the narcosis on the infants is notable. Many are born oligopneic. They do not stir themselves, breathe infrequently and cry but little, are pale and flaccid. Such infants must be treated like those born to eclamptic mothers who have received large doses of morphine (warm baths, massage, etc.). Scopolamine is present in the infantile urine and a drop of the latter will dilate the pupil of a frog, although an infinitesimal quantity of the alkaloid suffices for this result. The percentage of children who become oligopneic under scopolamine is somewhat under twenty. Strassmann advised the general practitioner to use the drug tentatively if at all. It is best to wait until the clinicians come into closer agreement as to indications, dose, etc.

May 30 and June 6, 1911.

Salvarsan Milk.—Jesionek uses this term to denote human breast milk from a mother who has received salvarsan by injection or the milk of cows, goats, and other animals which have been similarly treated. Children with hereditary or acquired syphilis who ingest this milk are said to recover, temporarily at least, with remarkable promptitude. Unlike the tests of his predecessors those of the author readily showed the presence of arsenic in the milk. From experiments on animals as well as clinical experience it appears that the arsenic which enters the milk is able to cause toxic as well as salutary phenomena. The milk should also contain the endotoxins which result from the death of the spirochetes in consequence of the action of the salvarsan in the syphilitic mother. Salvarsan milk may be termed "syphilitic" or "nonsyphilitic," according to conditions which obtain. The author would much prefer to use the latter in treating a syphilitic child. It would be obtained by injecting a wetnurse or a milch animal.

Treatment of Infantile Paralysis.—Pürckhauer calls attention to the fact that some of the muscles in this affection are quite sound but have lost their elastic tension

from overstretching. Such muscles behave as if they were actually paralyzed. By shortening these muscles by approximating their insertions the elastic tension is restored and the muscle again becomes useful. Several cases are upon record (Wittek, Jones) in which muscles which had seemingly been paralyzed for years were restored to usefulness by simply flexing the limb and bandaging it in that position. The author's own material of nineteen cases of paralytic clubfoot was found to comprise no less than eight cases in which the muscles were overextended. In four of these tenotomy was required in addition to bandaging in the flexed position, but in the other four the condition recovered under mechanical correction alone.

Salvarsan in Anemia.—Leede refers to those cases of apparent pernicious anemia which actually depend on syphilitic infection. This etiological relationship he believes to be far less infrequent than might be believed. It must be borne in mind that the anemias caused by the bothriocephalus and ankylostoma were once placed under the head of pernicious anemia. Much care must be exercised in differential diagnosis for salvarsan seems to be contraindicated in true pernicious anemia.

Labyrinth Syphilis as an Early Secondary Manifestation.—Hintze of Bangkok, after citing a few cases of this lesion from literature, gives a personal case in which the labyrinth syndrome appeared in a man about nine months after the chancre was recognized. The patient had received a course of mercurial injections before the syndrome appeared and the treatment was pushed from that time on with iodide of potassium. In order to throw some light on this localization the author calls attention to the highly nervous temperament of the patient which invites a nervous localization. Syphilis is also far more widely diffused in tropical parts than in many localities in temperate zones, so that one looks for an infinite variety of lesions.

Shiga-Kruse Bacilli Carriers.—Boehncke states that carriers of dysentery bacilli are commonly believed to be unimportant from a sanitary standpoint, at least when compared with carriers of the germs of some other diseases. Referring to a petty epidemic of diarrhea in troops in which there was a suspicion of dysentery, it was found later that both typhoid and dysentery were present in the regiment, and that no less than twenty-five healthy soldiers presented the Shiga-Kruse bacilli in the stools. In the proved absence of infected water, milk, etc. it was assumed that carriers must be at fault. The lesson is not to discharge dysentery patients as cured unless a bacteriological study shows absence of germs from the bowel of the convalescent.

Familial Hypertrophic Neuritis.—Boveri first mentions the great infrequency of hypertrophic interstitial neuritis and our meager knowledge of the condition. It was described by Déjerine and Sotta in 1893 as an affection of children, a muscular atrophy in all the extremities, altered sensibility—including lightning pains—and distinct enlargement and induration of nerve trunks. Trophic disturbances were absent. Ataxia and the ocular symptoms of tabes were added later. At a still earlier period Gombault had described tabes in childhood of a character permitting identification with the newly described disease, so that the present author terms it the Gombault-Déjerine-Sotta type. Déjerine regarded it as true tabes developing in patients with interstitial neuritis. In 1906 Marie described a form of hypertrophic neuritis which differed from the preceding, and which he requested Boveri to investigate. The Marie syndrome is thus for a familial disease affecting six members of a given family, the mother and five children. In early childhood there is a difficulty in standing erect and walking. Toward puberty a pes equinovarus develops, apparently as a result of progressive muscular atrophy. The oldest child also developed a kyphoscoliosos. Nevertheless in the Marie type, while the consequences of muscular atrophy were in evidence, that deformity was not pronounced *per se* save in a flattening of the calves. In the Déjerine type the muscular atrophy was both universal and pronounced. Neither did the phenomena of ataxia develop in the familial cases, although the pupils were sluggish. Boveri was fortunate enough to obtain an autopsy upon the eldest child, through which it became apparent that the two types of disease had even a wide difference in their anatomical substratum. Aside from the tendency of the original type to extend to the ganglia, posterior roots, and cord, it was also a much more diffuse affection. In Boveri's case the muscles of the upper extremities were almost intact, and the chief muscular lesions were seated in the lower extremities. In other words, in Marie's type the neuritis is much less likely to be followed by muscular atrophy.

Typhoid Sepsis.—Jores uses this term for a pure sepsis due to the typhoid bacillus. In a given case a diagnosis could hardly have been made during life. The patient had early symptoms pointing in part to acute rheumatism and in part to acute gout (acute otitis externa). The temperature was high and a severe angina and rash suggested scarlatinal infection, although patient was forty-five years old. Sepsis of whatever origin seemed present eventually, but the slowness of the pulse apparently negatived such a diagnosis. The patient died somewhat suddenly in coma sixteen days after admission. The naked eye autopsy find was largely negative, but biological tests gave abundant evidences of typhoid sepsis. So little had typhoid been suspected in life that there is no mention of a Widal test in the history. The literature of pure typhoid sepsis is very scanty and the cases on record do not form a coherent type. The author believes that his patient was a germ carrier who in some manner infected himself (autobacterial reinfection). He hardly finds a parallel case among those on record.

Melanuria without Melanotic Tumor.—Zoeppritz, after relating a case in point, states his belief that it is extremely rare. There are indeed cases of blackened urine on record in which no evidence is adduced to show that the discoloration was due to melanin. In some cases it is expressly stated that melanin tests were negative. Some of the older clinicians (Senator, Garrod), who taught that melanuria was absolutely diagnostic of melanotic tumor, sought to show that when tumor formation was absent the blackened urine was due to some other coloring matter. While the author's patient had no melanoma he was suffering from a non-pigmented cancerous adenoma of the bowel, with secondary peritonitis. The ante-mortem diagnosis had naturally been melanotic tumor in the abdomen. There were absolutely no pigmentary anomalies anywhere in the body.

June 1 and June 8, 1911

Sensitiveness of the Tuberculous to Toxins Other Than Tuberculin.—Sorgo has tested tuberculous subjects in respect to their cutaneous sensitiveness to the toxins of cholera, dysentery, and diphtheria. In 1908 Entz had announced that von Pirquet's cutaneous tuberclin reaction was positive both in tuberculous and nontuberculous subjects, in children as well as in adults; and that both groups also reacted positively to all other disease toxins tested. The results were incomplete and no conclusions were drawn. The author took toxins of a certain concentration, testing them first on animals and injected them intracutaneously. He inoculated tuberculous subjects simultaneously with old tuberculin and the toxins of other diseases. It was apparent that the

patients reacted to all the various toxins more or less evenly. The generalization seems warranted that tuberculous subjects are allergic not only to tuberculin alone, but to bacterial toxins in general. This find antagonizes the doctrine of von Pirquet that his cutaneous reaction denotes specific allergy. It was further learned that heating the toxins to the point of robbing them of their toxicity to animals does not interfere with the occurrence of the reaction. The chief causal element then lies in the extreme supersensitiveness of the skin present in tuberculous subjects (who have not yet reached the cachectic stage). The substance which provokes the reaction cannot be the specific toxic principle hut some component present in all toxins.

Serodiagnosis of Pregnancy.—Mosbacher refers to the significance of the so-called epiphanin reaction in the diagnosis of pregnancy. This appears to hold good in the case of laboratory animals, but in its application to the human species the same objections obtain as in other recently described biological reactions; that is, the inconstancy in the results may be due to defective technique. There appears to be no doubt that the syncytial cell albumin of a given species of animal behaves as an antigen in the blood of an animal of the same species; and that a normal animal may be rendered anaphylactic thereby. An animal which has just become pregnant corresponds to a non-pregnant animal which has been sensibilized by the placental albumin. The sensibility of the pregnant animal appears to increase with pregnancy; and late in gestation the blood serum depresses the toxicity of the syncytiotoxins.

Radium in the Treatment of Scleroderma.—Benczur reports a case of scleroderma in a girl of eighteen, of four years standing, which yielded notably to radium emanations. The patient had chronic arthritis of the fingers and feet, together with scleroderma of the face, hands, legs, and breast. She was first treated unsuccessfully with fibrolysin, and eventually received 1,000 Maché units daily of radium emanations. For the first few days of treatment the pain in the joints increased, afterwards abating in severity, although it usually returned upon exposure to the radium. The patient perspired profusely during the treatment. The latter extended over five weeks and the hidebound skin loosened up to such a degree that patient could wrinkle her forehead, smile, etc., while in all localities other than the face the scleroderma vanished entirely. Owing to the production of hemoptysis the treatment had to be discontinued. Since fibrolysin has given some favorable results in this affection the author believes that a combination of the two new resources ought to prevail over certain cases of the malady.

Wassermann Reaction in Saturnism.—Schnitter corroborates the find of Dreyer that subjects with lead poisoning may at times react positively to the Wassermann reaction. He obtained four positive results in sixteen cases, but in one there was a possibility of old syphilis. The reaction probably appears only at a particular stage of development of the poisoning, at which the state of the blood is conceivably like that present in syphilis. In each positive result basophilic granular erythrocytes were present in abundance, and in each case the patient had been exposed to the toxic action of the lead for some months.

Influence of Dyspnea on Diabetes.—Von Mazyary-Kossa induced phloridzin diabetes in rabbits and then caused them to respire carbon dioxide. The excretion of water by the kidneys was but little affected, but the urinary sugar was reduced about 50 per cent. The author explains this action of the gas by the assumption that it paralyzes the renal nerves or their centers. That these nerves exert a powerful influence on glycosuria is shown by the fact that when divided in animals with phloridzin diabetes the sugar percentage is greatly diminished, even at times to the point of complete cessation. If the cord is divided urinary sugar is cut down, often as much as 90 per cent. The author believes that phloridzin diabetes is originally set up by the action of that substance on the renal nerves or their centers.

Aorta Angusta.—Krabbel refers to a congenital malformation and not to acquired aortic stenosis. Up to 1901 there were about 100 cases on record, all of autopsy material. Much light has gradually been thrown on obscure clinical phenomena, so that to-day aorta angusta is a well-known condition, clinical as well as pathological. This may, of course, complicate acquired disease of the heart and great blood-vessels, and *a priori* we should expect that such a malformation of the aorta would tend to accentuate a beginning cardiac lesion. The author's patient was seen but a day before his death. He was a young man, with the most marked evidences of cardiac insufficiency. The diagnosis was stenosis and insufficiency of the mitral valves. From older hospital records it was learned that nine months before the same diagnosis had been made, and that the personal history was negative beyond the fact that his heart had been affected for years and that he had gone through a probable pneumonia. Autopsy showed a greatly enlarged right heart, which included the apex and was much dilated. The left ventricle was notably small. The mitral orifice was only permeable to one finger. The aorta was very narrow, and its valves thin and fragile. The thoracic aorta barely admitted the little finger, the abdominal aorta being somewhat larger. There was chronic endocarditis at both the mitral and tricuspid valves and fatty degeneration of the myocardium. This case was fairly typical and illustrated the fact that patients with congenitally narrow aorta pass through childhood and adolescence very well, but that at the outset of the third decennium the heart begins to undergo rapid dilatation and insufficiency. The affection of the valves was superadded in the author's case, and prevailed over the mere aortic syndrome. Its relationship to acute rheumatism was obscure, there being no history of such an affection. Hence the clinical picture of mitral disease and the extreme hypertrophy and dilatation of the right heart.

Does Pregnancy Predispose to Carcinoma?—Lindstedi answers his own query by making the following points, based on statistics: Patients with the combination of cancer of the stomach and gravidity seem to show a lower age than would be accounted for by mere coincidence. Women with cancer of the stomach and uterus respectively occurring during the reproductive years quite frequently manifest the first symptoms of these lesions during a pregnancy. Cancer of the stomach, naturally more common in men than in women, shows in the reproductive period alone a greater incidence in women and a greater incidence in married than in single women.

An Assumed Pathognomonic Sign of Malarial Infection.—Carlo Mars has experimented on the presence, stated by Uroila, of a black pigment to be found in the urine of patients having malarial infection. The author tested seven cases for this pigment in various kinds of malarial infection. He finds that the malarial pigment found free in the blood, enclosed in the phagocytes, or fixed in the tissues does not pass into the urine. Hemosiderin, a substance less complex than melanin, may pass through the renal tubes and be present in the urinary sediment. He found no melanin in the urine tested, but a brown pigment similar to hemosiderin. This may be similar to that found in the blood of anemic patients, those who have parasitic hemoglobinuria, or poisoning with pyrogallic acid. The finding of malarial pigment in urine is not a diagnostic sign of value.—*Il Policlinico.*

Insurance Medicine.

SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

INTRODUCTORY REMARKS.

The quality of the work achieved by medical men interested in life insurance has not failed to share in the advance of general medicine, and it naturally follows that the medical directors are alert in securing better information and expect more efficient service than would have been possible in the earlier days of life insurance. These two bodies of men, the home office staff and the examiners in the field, have hitherto worked apart, and in order that they may be brought nearer to each other for a mutual exchange of ideas, it is proposed to devote space in this column to a series of contributions from those who have made this subject their life work. There was little to say in the old days when the companies were smaller, the examiners fewer in number, and the vast amount of valuable material in possession of the companies had not been threshed out. Even the home office staffs had not learned fully to realize the importance of the great quantities of valuable material lying dormant on the shelves. During those years the business of life insurance was conducted on profitable lines, but as competition became keener it behooved each company to do its best to keep up with the rival concerns. A more potent factor, however, than the prodding of competition was the natural progressive spirit of those to whom the welfare of the various companies was intrusted. As the experience of each company was gradually worked out, it became evident from time to time that considerable modifications of the old views were needed. In getting at these facts the companies did not work together. On the contrary, each one had its own corps of trained assistants and retained nearly all the information gained through its efforts for its own individual use. As time has gone by, however, a tendency has grown toward an interchange of views between the representatives of the companies, and there is now more than ever a combined effort to base the selection of risks on a definite and scientific foundation. This is found to be especially true of the medical and actuarial officers, and has been effected through the meetings of associations devoted to their special interests. These meetings have been profitable to the members, but there has been a very limited distribution of the proceedings among the general profession. While, then, a large amount of work has gone on and important results have been obtained, the field worker has had but little opportunity to derive much benefit from them.

The only practical way to reach the medical examiner is through the columns of a regular medical publication to which all contributors have equal access. Previous attempts in this direction have been either unwisely directed, or sporadic and short lived. The text books for life insurance examiners, while some of them are excellent, necessarily treat the subject in a more or less didactic way, many of the everyday but important practical points being outside of their range. It will be the object of a series of informal contributions under the head of "Suggestions to Medical Examiners" to present not only the practical side of insurance medicine, but also to explain the meaning of many of the requirements of the home office. It is frequently found that an examiner is at a complete loss to understand why certain additional information is wanted. As an examiner, he has had to work out his own salvation, assisted only by brief, concise communications from members of the busy home office staffs, too pressed for time to explain the bearing of their requests. Like other people, medical examiners dislike to work in the dark, and it is not a cause for wonder if they sometimes fail to grasp the point and even show signs of irritation over, what seem to them, useless questions. The conditions under which they follow their general practice differ widely from those which confront them as examiners, and it is only fair to them to take advantage of every opportunity to make them more familiar with the many intricacies involved in modern methods of selecting risks for life insurance. By the possession of a more complete understanding of the subject, they will recognize the importance of the requests from medical directors, many of which formerly seemed unreasonable and even irrelevant, and furthermore they will make their examinations with the demands of modern life insurance in mind, thereby lessening the call for subsequent communications from the main offices. And, still further, when the requests for additional requirements do come, they will cheerfully give the extra services called for. If success is attained in bringing the forces of the home office and the field closer together, in bringing them to work harmoniously, and in augmenting the good feeling already existing, the labors of both will become lighter and more pleasant.

The Medical Aspects of Modern Life Insurance.—By FREDERICK L. HOFFMAN. (See page 1.)

A Department of Insurance Medicine.—(See page 17.)

American Association of Medical Examiners; Eleventh Annual Meeting.—(See page 52.)

Defects and Anomalies Without Influence on Expectation of Life or Earning Capacity.—Grohmann says that if an applicant suffering from an unimportant defect or anomaly is refused insurance on the advice of the medical examiner both he and the insurance company suffer. It is therefore worth while to discuss what defects and anomalies are of no importance from insurance standpoint. Such defects may be divided into congenital and acquired, the latter being subdivided into those acquired through accident or injury, and those produced by disease. "Cripples" are included in the first division, such as persons lacking one or more fingers or toes, or even an arm or a leg, or simply persons having the misfortune of being born with lame or crooked limbs. In case the organism of such a person is otherwise normal there is no reason for refusing him or her insurance; on the other hand, freedom from paying premium in case the applicant becomes an invalid should seldom be included in the conditions of the policy for the existing defect or anomaly may predispose to such a helpless state.

Some general rule should hold true in case of defects or anomalies of special senses, for example, one-eyed applicants, persons hard of hearing, near-sighted, or far-sighted persons whose vision can be easily corrected by proper glasses. Complete blindness or deafness is different, of course, because of the increased risk of death or injury through accidents; dumb persons, on the other hand, should not be refused insurance.

Cretins and weak-minded persons should be excluded, this being really commanded by the civil law. Persons possessing defects or anomalies of the genital apparatus should not be excluded, if the excretory functions are not damaged; such defects are no obstacles to long life. Grohmann knew three such persons that lived beyond sixty

years. Congenital hernias are usually easily corrected and should not militate against insuring a child; the rare anomaly, transposition of the viscera, is of no significance. Various warts, fibromata, and naevi of the skin are likewise unimportant; nævus pigmentosee is a partial exception, because of possible malignant degeneration. Benign tumors, especially if easily removable, should likewise be treated with indulgence.

Acquired defects are easier to value from the insurance standpoint. Loss of a limb, in case of complete recovery from shock of operation may simply necessitate higher premium for a policy. Incomplete restoration of function in limbs, if it does not leave a person helpless or an invalid, should be treated in the same fashion. The older the person at the time of an accident the more likely is the latter to shorten his life. Uncomplicated fractures usually leave little or no trace; if lameness results this should not militate against an applicant. Acquired hernia should call for higher premium, even after cure, for predisposition remains. If not cured there is always the danger of complications. Burns should be judged according to extent and site; some time should pass before insuring an applicant who has just recovered from extensive burns.

Defects in consequence of disease are the hardest to deal with. Frequently the causative sickness cannot be diagnosed from the history or the physical examination. Loss of fingers or toes after a short inflammatory process is of no significance; if the process shows no inclination to end the matter should be judged differently. Fistula due to a local tuberculous disease should be judged in each individual case, for persons suffering from them may be healed and attain advanced age. Operation scars from excision of cervical glands should likewise be neglected, if no evidence of latent tuberculosis be discovered. Goitre is to be judged according to mechanical disturbance its presence produces or may produce. Hemorrhoids and other varices should be judged according to the cause of obstruction in circulation. Any evidence of syphilis, however quiescent the disease may have become, should always be considered as of great possible importance in shortening the applicant's life or diminishing his earning capacity. The presence of any general disease, together with a defect or an anomaly should, of course, exclude an applicant from participation in insurance.—*Blätter für Vertrauensärzte der Lebensversicherung*, March and April, 1911.

Urine Examination in Life Insurance—A Farce.—Henry R. Harrower says that examination of the urine, when careful and complete, is one of the best means of diagnosis that we possess. It is therefore easy to understand why uranalysis should be required of applicants for life insurance. The usual method pursued, however, results in farcical conclusions. Frequently the medical examiner analyses a specimen voided at the applicant's visit for physical examination. No pains are taken to obtain a sample of twenty-four hours' urine; some companies even prefer that a specimen voided in the presence of the physician be examined, so that deception may be prevented. Specific gravity is usually measured by the cheap urinometers, found in physicians' offices. The urine is then boiled and occasionally Heller's test for albumin is used in addition. Fehling's or Haines' test is used for sugar. Most insurance companies are satisfied with the examination such as sketched above. The specific gravity may be higher than the limits set in the instructions for medical examiners, yet it is possible that a single specimen taken in summer time may normally show a specific gravity between 1025 and 1030. Or the individual may have taken in his food little protein and much table salt, and thus raised the specific gravity of the urine. On the other hand, a low specific gravity might exist in a single specimen, depending upon the amount of water taken. As to examination for albumin, the tests used are frequently negative when a manifest disease of the kidney exists, or traces of albumin are shown in the absence of a serious disease. Could there not be an alimentary aluminuria? Could not urine contain occasionally traces of albumin, just as its content in phosphates or chlorides varies daily? Harrower has seen the appearance of albumin and casts depending upon high acidity of the urine, the correction of which resulted in the disappearance of the abdominal elements. It may therefore be concluded that the presence of albumin may be neglected unless the albuminuria is a constant phenomenon. So far as sugar is concerned, it has been shown that Fehling's reagent may be reduced by many other substances in addition to sugar. The phenylhydrazin and the fermentation tests have, therefore, been proposed, but even then, when but a single specimen is examined, alimentary glycosuria is not excluded.

Harrower proposes that in cases of policies of $1,000 and more the urine should be examined by a specialist, who should perform chemical tests for albumin, sugar, bile pigments, blood, and indican, and, in addition, quantitative tests for urea, acidity, ammonia, and perhaps phosphates and chlorides. Then a careful microscopical examination of sediment should follow. Such a test would show whether the individual is in normal condition of metabolic equilibrium; whether or not a disturbance of the kidney or other parts of the genitourinary apparatus exists; whether a high degree of intestinal putrefaction is present. Harrower concludes that this would allow the insurance of many who are now excluded, and would exclude others who now prove to be bad risks.—*Zeitschrift für Versicherungsmedizin*, February, 1911.

Urine Examination in Life Insurance—A Farce?—Leopold Feilchenfeld answers an article by Harrower with the above title. He grants that there is some truth in Harrower's statements, only they are exaggerated and wrongly applied. The usual examination of urine for life insurance purposes is not scientifically complete, but it is not the aim of the examiner to discover any small abnormalities, the practical significance of which is not at all definitely known. For instance, what would be the meaning of increase in phosphates, chlorides, urea, or uric acid? The insurance companies want simply to exclude serious illness, and especially diabetes and nephritis. Special methods would show "traces of albumin" in otherwise quite healthy persons. Harrower is right in condemning Fehling's test, but most examiners have already substituted Nylander's reagent for Fehling's. The writer warns against making the medical examinations too complicated, in any case, as there is a growing tendency among life insurance companies to do as much as possible without medical advice; for instance, a certificate from the applicant's family physician is now rarely called for. It may be that in the future even the medical examiner's services will be only exceptionally called for. Feilchenfeld concludes that the present method of having the medical examiner perform the uranalysis is quite acceptable. The services of a specialist should be required only if the results obtained by the examiner require control in any particular and difficult case.—*Zeitschrift für Versicherungsmedizin*, April, 1911.

The Physiology and Pathology of Senescence.—H. E. MacDonald not only agrees with Minot that senescence is not in itself a diesase, but declares that the process is certainly intended to be beneficent. It is harmful only when carried too far, when it assumes all the characters of disease. Like inflammation, senescence is pathological only when carried to excess. Moreover, MacDonald believes that the two processes are identical as the result of both inflammation and senescence is fibrosis, and the natural inference is that inflammation is simply accelerated senescence. According to Weismann, unicellular organisms which propagate by cleavage are potentially immortal. Germinal cells are immortal, while somatic cells are protec-

tive, and have lost the germinal property. The higher the evolution of the animal the longer the life. The cells set apart to combat parasites, isolate the infected region with a wall of connective tissue, but the toughening process characteristic of senescence is accomplished at the expense of functioning cells and thus the same agent which protects ultimately destroys.

The child has less combative powers against disease, but greater recuperative powers than the adult. The prevalence of infections among the young indicate that senescence both protects the body from microbes and produces degenerative diseases. Men who age slowly are longer susceptible to zymotic diseases, and those who inherit a tendency to become prematurely old are very refractive to infection. It is evident that in the matter of resistance families may be divided into two classes, which may be termed the tender and the indurated. Members of the tender families are in danger for a longer period of contracting bacterial diseases, but, these escaped, senescence does not destroy them until they have reached a very old age. On the other hand, members of indurated families resist infections well, but grow senile early. Insurance companies look with suspicion upon the applicant whose family history gives indication of his belonging to a tender family. This is not the right mode of regarding the question. A man with tuberculosis in the family history is a decreasing risk—dangerous for term insurance; much better for a whole life policy. Individuals with apoplexy in their parentage belong to the indurated class—good risks while young, but hazardous as the years go by; safe for term insurance, but dangerous for life. Indians and negroes belong to the tender class, but are the most apt to produce centenarians. Civilized people are the most highly indurated. It is true that through natural selection inherited immunity has increased, but cirrhotic diseases, which are the end results of immunity, have increased at the same rate. MacDonald argues that those who would lessen infection by producing immunity are putting the cart before the horse. In the same ratio as the number of microbes are decreased will senescence decrease.—*Southern California Practitioner,* May, 1911.

Diatheses from the Modern Viewpoint.—A symposium on this subject was held at the recent German Congress for Internal Medicine in Wiesbaden. His, representing the internists, defined a diathesis as a basic condition due to inheritance or individual disposition, which is expressed in manifold ways. Thus there is a diathesis expressed by gout, obesity, and diabetes, and more distantly by cholelithiasis, arteriosclerosis, and certain dermatoses and psychoses. Children of such stock exhibit concentrated urine, bed-wetting, chlorosis, migraine, asthma, and psoriasis. The diathesis underlying all these affections is the arthritism of French clinicians, a condition believed to be peculiar to the intellectual and the sedentary, and to degenerating races. To gout in this diathesis should be added chronic arthritis. Another basic condition to be regarded as a diathesis is that known variously as rachitis, in the broadest sense of the term, and also as the exudative or the spasmophilic diathesis. A third is infantilism in its widest sense. A group of affections, all of which are characterized by eosinophilia is believed to indicate a special diathesis. The neuropathic constitution or diathesis is well known. Pfaundler spoke for the pediatrists. Scrofula, he said, is not in itself a diathesis, for it rests upon a more deeply seated condition, the so-called status thymicolymphaticus, the "pasty" diathesis. This notion is so expanded as to embrace a large proportion of infantile ailments—enlarged lymph nodes, catarrhal processes, dermatoses, vasomtor disturbances, neuropathies, dystrophies, spasmophilia, etc. The author alludes to this polymorphism as representing a "colossal mutation." The exudative diathesis is naturally comprised under the preceding. Bloch represented the dermatologists. The most important diathesis to the latter is the arthritism of the French. This he believes to be due to allergy or supersensitiveness to certain irritants, both exogenous and endogenous. He applies the term physiological diathesis to puberty, gestation, and the climacteric. Mendelssohn, speaking for French medicine, laid most weight on the inborn element which represents sluggish nutrition. The life of the arthritic is often one long clinical history. The infinite variety of individual disorders best illustrates the intimate nature of the underlying disposition. —*Deutsche medizinische Wochenschrift,* May 4, 1911.

Insurance Nursing in Rochester.—Nellie C. Linsay, R.N., outlines the work which she is called upon to do in her capacity as visiting nurse for the Metropolitan Life Insurance Company in Rochester, N. Y. The actual treatment and care given by the nurse is the least of her activities. From the standpoint of prevention her value consists in the education, along sanitary and hygienic lines, which she spreads broadcast among the homes that she visits. Miss Linsay began her insurance work in Rochester, on September 1, 1910. In the six months following she made 1118 visits on 278 patients. These are industrial policyholders, and many of them are very poor, as well as ignorant. The agent, in one of his periodical calls finds something wrong, and the nurse is sent to investigate. If she finds a child is really ill, and the parents are unable to pay for medical attendance, the overseer of the poor is notified and he sends a physician or has the patient admitted to hospital. In other cases of serious illness a special nurse is detailed to the case. The people grow to regard the visiting nurse as a confidant, and often call upon her for advice in sanitary and other matters, even when there is no illness in the family.—*The American Journal of Nursing,* May, 1911.

Increasing Insurance.—Twenty years ago the average life insurance policy was for $2,500; now it is more than $3,000.—*Baltimore American.*

Accident Days.—Statistics based upon the results of an investigation into the causes of accidents among industrial workers, carried on for a number of years in Germany, show that the greatest number of casualties occur on Saturday, while Monday is a close second. The large number of accidents on Saturdays is generally explained by the fatigue of the week telling on the men, but it is noted also that the Monday accidents are about as numerous. This gives rise to the suggestion that the day of rest is sometimes not too wisely spent.

Age and Sex in Relation to Accidents.—German statistics, recently published, of accidents among laborers of all classes show that the percentage of the number of injured increases progressively from 4 in each 1,000 male workers between the ages of 18 and 20 to 16 per 1,000 among those between 60 and 70 years. At no time of life, however, is the average number of women workers injured greater than 3.25 per 1,000.

Causes of Death.—Naturally, applicants for life insurance may be expected to put as good a face as possible on the reports concerning relatives and the causes of their deaths, but they sometimes make rather amusing statements. Some one has collected a few of these which were originally published in the *British Medical Journal:* "Mother died in infancy." "Father went to bed feeling well, and the next morning woke up dead." "Grandfather died suddenly at the age of 103. Up to this time he bid fair to reach a ripe old age." "Applicant does not know cause of mother's death, but states that she fully recovered from her last illness." "Applicant has never been fatally sick." "Applicant's brother, who was an infant, died when he was a mere child." "Grandfather died from gunshot wound, caused by an arrow shot by an Indian." "Applicant's fraternal parents died when he was a child." "Mother's last illness was caused from chronic rheumatism, but she was cured before death." "Father died suddenly; nothing serious." There is a delightful innocence about some of these. Take the last, for example. This has a Western flavor, as though the applicant appreciated father's having made little fuss about it. When the time came he simply went, that was all.—*Journal of the American Medical Association.*

Book Reviews.

Practical Dietetics. With Reference to Diet in Disease. By Alida Frances Pattee, Graduate, Department of Household Arts, State Normal School, Framingham, Mass.; late Instructor in Dietetics, Bellevue Training School for Nurses, Bellevue Hospital, New York City; former Instructor at Mount Sinai, Hahnemann, and the Flower Hospital Training School for Nurses, New York City; Lakeside, St. Mary's, Trinity, and Wisconsin Training Schools for Nurses, Milwaukee, Wis.; St. Joseph's Hospital, Chicago, Ill.; St. Vincent de Paul Hospital, Brockville, Ont., Can. Sixth Edition. $1.50. New York: A. F. Pattee, 1910.

This book is now in the sixth edition, and covers the field very thoroughly. The large number of clear and intelligible recipes for the preparation of various dishes for the patient should make it indispensable to those who have occasion to prepare food for the sick. The special diets drescribed for certain diseases, and the tabular estimates of food values, etc., go to make an invaluable book of reference for nurses. The writings of well-known physicians who are authorities on the subject have been wisely consulted in the preparation of the second portion, "Diet and Disease."

American Practice of Surgery. A Complete System of the Science and Art of Surgery by Representative Surgeons of the United States and Canada. Editors: Joseph D. Bryant, M.D., LL.D.; Albert H. Buck, M.D., of New York City. Complete in Eight Volumes. Profusely illustrated. Volume VIII. New York: William Wood & Company, 1911.

With this volume is completed this great system of surgery, the largest and most exhaustive work on this branch, so far as the reviewer knows, in any language. The volume opens with the concluding portion of Regional Surgery. The first article is on Intrathoracic Surgery, by Joseph and J. Louis Ransahoff of Cincinnati. In this the authors describe the method of operating in the differential pressure chamber as modified and improved by Willy Meyer. Then follow articles on the surgery of the adominal organs: the spleen, by A. E. Garrow of Montreal; the kidneys and ureters, by James Bell of Montreal; the pancreas, by G. D. Stewart of New York; the liver, gallbladder, and biliary passages, also by Stewart; urinary bladder and prostate, by A. H. Ferguson of Chicago; the ovaries and Fallopian tubes, by B. R. Schenck of Detroit; the uterus and its ligaments, by John B. Murphy and F. W. Lynch of Chicago. Two brief but very valuable articles, on "Extrauterine Pregnancy" and "The Cesarean Section and Its Substitutes," are contributed by Lewis S. McMurtry of Louisville. With these closes what may be called the practical portion of the work.

The remaining half of the volume contains a number of valuable and interesting articles, beginning with one entitled "The Law in Its Relations to the Practice of Surgery," by Stephen and Sidney Smith of New York, in which the mutual obligations of the surgeon and his patient are discussed at length. Part XVIII, with which the volume closes, is entitled "Administrative Surgical Work," the first article being a timely one on "Hospitals and Hospital Management, More Particularly with Reference to the Surgical Needs of These Institutions," by C. R. Holmes of Cincinnati. The author condemns the recent movement to abandon the pavilion plan of hospital construction and adopt the "sky-scraper" in its place, the only argument in favor of which is the economy of ground. The new Rudolph Virchow Hospital in Berlin is described by him at length as being a type of what a large urban hospital should be. An article on "Military Surgery" by Major Charles Lynch treats of the military medical organization of the United States, the personnel, the rank and pay of the medical officers, their duties; field hospitals, convalescent camps, transportation of the wounded, and everything that is peculiar to this branch of medicine. It is illustrated with a number of interesting photographs of the Japanese military hospitals, hospital cars, supply depots, etc., during the war with Russia. Following this is another excellent article on "Naval Surgery," by Surgeon-General C. F. Stokes, U. S. N., in which the peculiar difficulties of caring for the wounded on shipboard during an engagement are well described and illustrated by photographs of the wounded in the Russo-Japanese war. One picture, in particular, of the boat deck of the *Orel* after the battle of Japan Sea, shows how impossible it often is to give first-aid to the wounded during a battle.

An appendix contains an article on "The Relation of Blood-Pressure to Surgery," by J. E. Sweet of Philadelphia, in which this new subject is excellently treated, and the indications for the administration of vasoconstrictors (not alcohol) are demonstrated. A very full and well arranged general index completes the volume.

It is impossible to review adequately a work of this character in the limited space at command, for it is really a collection of over one hundred monographs, embracing the entire domain of surgery, each one of which is important enough to claim a critical notice for itself. One is struck, in studying the volumes of the series, by the discriminating sense of proportion displayed by the editors in fixing limits to the work of the various authors. It is seldom that one feels that too much space is given to a comparatively unimportant subject or that the treatment of an important subject has been kept within too narrow compass. This is no doubt due to the ideal editorial association of a practical surgeon, himself a writer and an acknowledged authority, with an editor of the widest experience and reputation. The illustrations are numerous and of a superior order, consisting of half-tones, line drawings, and full-page plates, and the typography, paper, and binding make the volumes most pleasing to the eye.

Diseases of the Anus, Rectum, and Sigmoid. For the Use of Students and General Practitioners. By Samuel T. Earle, M.D., Professor Emeritus of Diseases of the Rectum in the Baltimore Medical College, Surgeon in Charge of Rectal Diseases at St. Joseph's Hospital, the Hebrew Hospital, and the Hospital for Women. With 152 illustrations in the text. Price, $5.00 net. Philadelphia and London: J. B. Lippincott, 1911.

In preparing this book the aim of the author has been to include the most recent and effective methods of cure and to give these comprehensively and succinctly, so that they may be readily available to the busy practitioner. There are many conditions in the province of rectal surgery that the general practitioner is frequently compelled to treat unaided, and that he is none the less competent to treat. With these guiding thoughts the author has succeeded in presenting an eminently useful book, available both for study and reference. As an example of the comprehensive manner in which the various subjects are discussed may be mentioned the chapter on constipation. All the available methods of treatment are given: massage, hydrotherapy, electricity, medicinal and operative treatment, and psychotherapy. The subjects of anorectal fistula and hemorrhoids are covered in satisfying detail. The rarer conditions affecting the lower end of the alimentary tract, such as infection by *Bilharzia hematobia*, actinomycosis, spontaneous gangrene of the rectum, hysterical or irritable rectum, and neuralgia of the rectum, are all described in addition to the more common disorders. The author advocates the use of general anesthesia in operative work on the rectum, although he describes the method of applying local anesthesia. He apparently ignores the utility of sterile water anesthesia, although he devotes several pages to the subject of quinin and urea hydrochlorid as a local anesthetic and to the subject of spinal anesthesia. The most recent writings on various subjects are quoted in full. The illustrations are numerous and contribute to the lucidity of the text. The author has succeeded in covering this extensive field in a satisfactory manner.

Les Appareils Plâtrés. Par le Docteur Jean Privat, Assistant a Paris du Dr. Calot, de Berck. Préface du Dr. Calot. Avec 268 figures originales dans le texte. Prix, 6 fr. Paris: A. Maloine; Toulouse: Edourd Privat, 1910.

This volume presents every little detail connected with the subject of plaster of Paris apparatus. The text is accompanied by a surprisingly large number of original drawings showing every step in the preparation and application of the apparatus. Apparently nothing of value that relates to this subject has been omitted. The book is divided into three parts. The first treats of the preparation of the apparatus and of the patient. The second part deals with the manner of applying various forms of plaster of Paris apparatus, the indications and technique of each kind being presented in great detail. The third division of the book takes up the subject of the care of the apparatus and the means that may be employed to add to the comfort of the patient. One notes the simplicity of the author's technique. This is particularly manifested in the large numbers of improvised methods of suspending the patient preparatory to the application of a plaster jacket. This work may be recommended to all those who do only a little of this kind of work as well as to those who frequently employ plaster of Paris apparatus, as an eminently useful book that cannot fail to offer many valuable suggestions.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

NEVADA STATE BOARD OF MEDICAL EXAMINERS.

May 1, 2, 3, 1911.

ANATOMY.

1. Locate Peyer's patches or glands. Of what are they composed?
2. What muscle closes the lips?
3. Name the seven openings of the pharynx.
4. Name the duct or canal of the pancreas.
5. What is the action of the cremaster muscle?
6. Where is the coracoid process? Of what bone is it a part?
7. Describe the diaphragm; name its openings and what passes through them.
8. Give origin, termination, and division of the large intestine.
9-10. Name the cartilages of the larynx, the single ones and the pairs.

PHYSIOLOGY.

1. Give the average number of red corpuscles per c.mm. in the human blood. (*a*) What is the function of red corpuscles, and upon the presence of what substance does that function depend?
2. Give approximate weight of blood to weight of human body.
3. What secretion contains a free acid?
4. What are the principal functions of the medulla oblongata?
5. What do you know about the circulation of the lymph?
6. What is the general physiological importance of bile?
7. What is the final fate of fat in the tissues?
8. Where is urea formed in the body?
9. What percentage of urea does normal urine contain?
10. Give the structural changes in the uterus during menstruation. (*a*) Upon what organs does the periodicity of these phenomena depend?

MATERIA MEDICA AND THERAPEUTICS.

1. Give six methods by which medicines are administered.
2. Give general principles governing the dose as to sex, age, weight. Give exceptions to the rule.
3. Give rules for converting apothecaries into metric weights and measures; metric into apothecaries.
4. Give rule as to time and frequency of administration of remedies.
5. Give general rules for dosage of tincture; fluid and solid extracts.
6. Give three methods of action by which a drug may slow the heart action. Three by which it may quicken the heart action.
7. What is a specific? What is bromism? What is iodism?
8. Describe the difference of action of a saline and a vegetable cathartic.
9. Give the probable course of a dose of iron. What quantity is absorbed daily?
10. What is aconite? Describe its physiological action

CHEMISTRY AND TOXICOLOGY.

1. Name the abnormal constituents of urine.
2. With what class of drugs are the heavy metals incompatible?
3. Define a chemical compound; a mixture. Give examples.
4. What are the constituents of pure air? Note changes that take place in overcrowded room. Give test for excess of carbonic oxide.
5. Where and in what form is salol absorbed? How eliminated?
6. Give symptoms of poisoning by coal tar antipyretics.
7. Give symptoms of chloral poisoning. What commonly used proprietary articles may produce chloral poisoning?
8. Give symptoms of acute and chronic arsenical poisoning.
9. Describe a case of phenol poisoning. Give danger signal when used in medicinal doses or locally.
10. What are the symptoms of the cumulative effect of digitalis?

BACTERIOLOGY.

1. Give the principles of the methods of examining and staining for bacteria.
2. Given a specimen of sputum describe the steps taken to find the presence or absence of the tubercle bacillus.
3. Describe the preparation of and the varieties of culture media.
4. What is a bacterial vaccine, and how it is made?
5. How do bacteria multiply?
6. Differentiate between the *B. coli communis* and *B. typhosus.*
7. How would you obtain a culture from a case of diphtheria, and describe method used in staining?
8. Give in detail the method you would use to control an epidemic of scarlet fever.
9. What microorganisms are most commonly associated with suppuration?
10. Describe the *Bacillus anthracis.*

PATHOLOGY.

1. Describe the steps necessary to mount a specimen for pathological examination.
2. Describe the appearance, under the microscope, of a healed tubercle.
3. Differentiate microscopically between carcinoma and sarcoma.
4. Give the pathology of myxedema.
5. Give the pathology of syringomyelia.
6. Give the pathology of scurvy.
7. Describe the process of hyaline degeneration; fatty degeneration.
8. Describe the conditions of the intestinal tract during an attack of summer diarrhea.
9. What are local infections?
10. Define anemia, hyperemia, immunity.

PRACTICE OF MEDICINE.

1. Give the symptoms and treatment of sciatica.
2. What is chlorosis, and how should it be treated?
3. Give the symptoms and treatment of cirrhosis of the liver.
4. Give the symptoms, diagnosis, and treatment of influenza.
5. Give the etiology, symptoms, and treatment of acute peritonitis.
6. Define vocal fremitus, and state its significance in pulmonary disease.
7. Define bronchiectasis, and give symptomatology and treatment.
8. Differentiate a hemic murmur from a murmur of organic disease.
9. What is acute ascending paralysis, its etiology, symptoms, and treatment?
10. Poisoning by what drug would be indicated by the following symptoms: Flushed face, thirst, dry fauces, double vision, dilated pupils, giddiness, delirium, and stupor? What treatment should be employed?

OBSTETRICS.

1. How would you distinguish a primiparous from a multiparous woman?
2. Of what use is the "bag of waters"? When would you rupture it?
3. What is the hour-glass contraction? How would you overcome it to remove the placenta?
4. What is meant by "prolapsus of the funis"? What are the dangers, and how would you treat it?
5. What means would you employ to prevent laceration of the perineum when the head is well down and the expulsive pains strong?
6. Give symptoms of pregnancy and their relative importance.
7. Name the external and internal female organs of generation.
8. Give cause and treatment of flatulent distention of the abdomen following labor.
9. What do you understand by a "dry labor," and what disadvantages may result from it?
10. How long after the child is born would you wait for the placenta to pass?

SURGERY.

1. Give as many of the causes as you know of for delayed union or nonunion of the fractures. (*a*) Give a method of operation for ununited fractures.
2. Describe your operation for the radical cure of inguinal hernia.
3. What is a Colles' fracture?
4. Give diagnostic signs of fracture of neck of the femur.
5. Give the symptoms of abscess of cerebrum.
6. Name and describe two operations for the removal of hemorrhoids.
7. Give surgical treatment for volvulus.

8. Name and describe two methods for the removal of vesical calculus.
9. Symptoms and radical treatment for gastric ulcer.
10. Etiology and treatment of lymphangitis.

GENITOURINARY SURGERY AND DERMATOLOGY.

1. Differentiate uremic coma.
2. How would you treat a case of renal colic?
3. What are the symptoms and treatment of chronic urethritis?
4. What are the causes, symptoms, and treatment of neuralgia of the testicle?
5. What is the predisposing cause and treatment of epithelioma of the scrotum?
6. What is lepra?
7. What is erythema hyperæmicum?
8. What are the causes and treatment of a carbuncle?
9. Describe the salvarsan treatment for syphilis.
10. Differentially diagnose tinea tonsurans from alopecia areata.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

NEVADA STATE BOARD OF MEDICAL EXAMINERS.

May 1, 2, 3, 1911.

ANATOMY.

1. Peyer's patches or glands are situated in the small intestine, chiefly in the ileum. They are opposite the mesenteric attachment. They are composed of solitary follicles (of lymphoid tissue).
2. The orbicularis oris muscle closes the lips.
3. The *seven openings of the pharynx* are: Two Eustachian tubes, larynx, esophagus, mouth, and two posterior nares.
4. The duct of the pancreas is Wirsung's duct.
5. The cremaster muscle raises the testicle and draws it towards the external abdominal ring.
6. The coracoid process may be felt about an inch below the junction of the middle and outer thirds of the clavicle; it is a part of the scapula.
7. The *diaphragm* is a musculofibrous septum which divides the thoracic from the abdominal cavity; it is fan-shaped; the broad elliptical portion is horizontal, and the crura are vertical. It is attached to the ensiform, to the internal surfaces of the lower six costal cartilages, to bodies and intervertebral substances of first, second, and third lumbar vertebræ. Its *openings* are: (1) The aortic, transmitting the aorta, vena azygos major, and the thoracic duct; (2) the esophageal, transmitting the esophagus, pneumogastric nerves, and some small esophageal arteries; (3) the opening for the vena cava, transmitting the inferior vena cava, and small branches of the right phrenic nerve; (4) the right crural, transmitting the right splanchnic nerves; (5) the left crural, transmitting the left splanchnic nerves and the vena azygos minor.
8. The large intestine begins at the termination of the ileum, in the right inguinal region, and terminates at the anus. It is divided into: cecum, colon (ascending, transverse, and descending), sigmoid flexure, rectum, and anal canal.
9 and 10. There are *three single* cartilages of the larynx: thyroid, cricoid, and epiglottis; and *three pairs:* arytenoids, cuneiforms, and cornicula laryngis.

PHYSIOLOGY.

1. There are about 5,000,000 red corpuscles per c.mm. in the male, and about 4,500,000 in the female. The function of the red corpuscles is to carry oxygen to the tissues; this depends on the presence of hemoglobin.
2. The weight of blood is approximately about 1/13 of the body weight.
3. The gastric juice contains a free acid (hydrochloric acid).
4. The *functions of the medulla oblongata* are: (1) It is a conductor of nervous impulses or impressions from the cord to the cerebrum, from the brain to the spinal cord, also of coordinating impulses from the cerebellum to the cord; (2) it contains collections of gray matter which serve as special nerve centers for the following functions or actions: respiration, salivary secretion, mastication, sucking, deglutition, vomiting, voice, facial expression; it also contains the cardiac and vasomotor centers.
5. The lymphatic circulation is, strictly speaking, not a circulation at all; since the lymph flows only in one direction, namely, toward the heart. The lymph capillaries take up any excess of the blood plasma which is not required for the nutrition of the tissues. These capillaries consist of a single layer of epithelium, and empty themselves into vessels very like the veins. The lymph vessels are well provided with valves, which are so closely approximated as to give the vessels a beaded appearance. All the lymphatic vessels, except those of the right upper half of the body, empty into the thoracic duct, which terminates in the left subclavian vein, where the left internal jugular vein also enters. Those from the right upper half of the body discharge into the right lymphatic duct, which, in turn, empties into the right subclavian vein at its junction with the right internal jugular vein.
6. *The functions of the bile* are: (1) To assist in the emulsification and saponification of fats; (2) to aid in the absorption of fats; (3) to stimulate the cells of the intestine to increased secretory activity, and so promote peristalsis, and at the same time tend to keep the feces moist; (4) to eliminate waste products of metabolism, such as lecithin and cholesterin; (5) it has a slight action in converting starch into sugar; (6) it neutralizes the acid chyme from the stomach and thus inhibits peptic digestion; (7) it has a very feeble antiseptic action.
7. *The fate of fat in the tissues:* "(1) It may be oxidized with the formation of heat energy; (2) it may be stored in the tissues as part of the body fat; (3) it may be synthesized with other substances to form some more complex constituent of the body, such as lecithin; (4) according to some authors, it may serve under certain conditions as a source of sugar."—(Howell.)
8. Urea is formed chiefly in the liver; probably also in some other organs or tissues not yet determined.
9. The urine contains about 2 per cent. of urea.
10. See Williams' "Obstetrics" (1909), page 82; or Hirst's "Obstetrics" (1909), pages 57 and 65.

MATERIA MEDICA AND THERAPEUTICS.

1. *Medicine can be administered:* (1) By the mouth; (2) by the rectum; (3) by inhalation; (4) by inunction; (5) hypodermically; (6) by intravenous injection; (7) by fumigation; (8) by cataphoresis.
2. As a general rule women require smaller doses than men; and heavy people larger doses than slight ones.
To determine the proper dosage for a child: Let x = the age of a patient; then $\frac{x}{x+12}$ = the fraction of the adult dose which the patient should receive. Thus, a patient of four years old should receive $\frac{4}{4+12} = \frac{4}{16} = \frac{1}{4}$ of an adult dose.
Children bear opiates badly; but they can take relatively large doses of belladonna, calomel, ipecac, arsenic, rhubarb.
3. Roughly, 1 gram may be said to be equivalent to 15½ grains; 1 grain to be equivalent to 0.06 gram; and 1 minim to be equivalent to 0.06 c.c.
4. Often it is immaterial when a medicine is given; often too, the needs of the body (such as sleep and meals) indicate the time when the medicine should be administered. As a rule medicines intended to act on the stomach should be given before meals; others an hour or two after meals. Irritant medicines (such as arsenic) should be given soon after meals. Slowly acting purgatives are given at bedtime, hypnotics at or before bedtime, santonin at night.
The frequency must depend on the action of the drug and the therapeutic effect desired. Generally, "three times a day," with reference to meals, is a good rule; but drugs with transient effect (such as nitroglycerin, ammonium carbonate, hydrocyanic acid) may be given more frequently; and those which have a sustained action (such as quinine, digitalis, arsenic) may be given less frequently.
5. As a general rule, *tinctures* may be given in doses of from 5 to 60 minims; *extracts*, 5 grains; *fluid extracts*, 10 minims. But the exceptions are so numerous that these rules have little or no value.
6. *A drug may slow the heart action* by: (1) Depressing the cardiac muscle; (2) by stimulating the inhibitory mechanism of the heart; (3) by depressing the accelerator mechanism of the heart.
A drug may quicken the heart action by the opposite of the above methods.
7. A *specific* is a remedy which has a definite curative action in relation to a particular disease, such as quinine in malaria.
Bromism is a condition which results from the long-continued use of bromids. This condition is characterized by headache, coldness of the extremities, feebleness of heart action, somnolence, anorexia, apathy, pallor of the skin, an acne eruption, and lowered sensibility of the fauces. There may be loss of sexual power, with atrophy of the testes and mamma.

Iodism is the term applied to the condition produced by the prolonged use of iodin and its compounds. It is characterized by violent coryza, headache, a metallic taste in the mouth, increased salivary secretion, gastric irritation, and an acne rash.

8. *Salines* "act by stimulating the intestinal glands to increased secretion, and by their low diffusibility impede reabsorption, causing an accumulation of fluid in the intestinal tract which, partly from the effect of gravity and partly by gentle stimulation of peristalsis excited by distention, reaches the rectum and produces a copious evacuation."—(Potter.)

A *vegetable cathartic* causes active peristalsis and increased secretion of the intestinal glands, with irritation.

9. "In the stomach all iron preparations are changed to the chloride by the hydrochloric acid of the gastric juice, and in the duodenum to an alkaline albuminate. The greater portion is carried on through the intestinal canal, where it is converted into a sulphide, which blackens the feces; a part, however, is absorbed by the intestinal epithelium in solid form and perhaps in solution. After reaching the blood by way of the lymph channels this small quantity of absorbed iron is deposited in the spleen, where it may undergo some changes, is again taken up by the blood and deposited in the liver and perhaps in the bone marrow. In the liver the originally inorganic iron is converted into higher forms and eventually into hemoglobin, ferratin being probably one step in the series. When there is no deficiency of iron in the system the liver slowly yields its store to the blood again, to be carried to the cecum and large intestine, by the epithelium of which it is finally excreted."—(Potter's *Therapeutics, Materia Medica,* etc.)

10. Aconite is the dried root of *Aconitum napellus.* It first stimulates and then paralyzes the heart and also the sensory nerves. it lowers blood-pressure, dilates the peripheral blood-vessels, is a respiratory sedative, reduces body temperature, and is a diuretic and diaphoretic.

CHEMISTRY AND TOXICOLOGY.

1. *Abnormal constituents of urine:* Albumin, sugar, blood, pus, bile, mucus, chyle, bacteria, casts, parasites.

2. Alkaloids.

3. A *chemical compound* is a substance containing two or more elements chemically united in definite proportions, as chloroform, phenol. A *mixture* is the product obtained by uniting into a more or less homogeneous whole two or more substances, whether elements or compounds, and without any chemical union, as milk and water.

4. The *constituents of pure air* are: Oxygen, nitrogen (including argon, etc.), and carbon dioxide. In an overcrowded room the oxygen is diminished, the nitrogen remains about the same, the carbon dioxide is increased, various organic products appear.

The changes produced in the *air* by respiration are:

	INSPIRED AIR.	EXPIRED AIR.
Oxygen	21 per cent.	16.6 per cent.
Nitrogen	79 per cent.	79 per cent.
Carbon dioxide	0.04 per cent.	4.4 per cent.
Other gases	Rare.	Often present
Watery vapor	Variable.	Saturated.
Temperature	Variable.	That of body.
Volume	Varies.	Diminished.
Bacteria	Always present.	None.
Dust	Always present	None.

Carbonic oxide is *carbon monoxide.*

5. Salol is decomposed in the small intestine into phenol and salicylic acid. It is absorbed in the small intestine and eliminated in the urine.

6. Lividity, restlessness, dyspnea, cold perspiration, chills, convulsions, lowered blood-pressure, slow respiration, vomiting, motor paralysis, and coma.

7. *Symptoms of chloral poisoning:* Deep sleep, accelerated pulse, dilated pupils, deep and irregular respiration. Later the face becomes white or livid, the pupils contracted, body temperature falls, circulation and respiration become weaker.

Chloral poisoning may be produced by: Chloralose, chloralamid, dormiol.

8. The *symptoms of acute arsenical poisoning:* "In acute cases the symptoms usually begin in from 20 to 45 minutes. Nausea and faintness. Violent, burning pain in the stomach, which becomes more and more intense, and increases on pressure. Persisting and distressing vomiting of matters, sometimes brown or gray, or streaked with blood, or green (Paris green). Purging. More or less severe cramps in the lower extremities."

In *chronic arsenical poisoning:* "Inflammation of conjunctivæ with intolerance of light. Irritation of the skin, with eruption (eczema arsenicale), local paralysis, great weakness and emaciation, exfoliation of the skin, and falling out of the hair."—(Witthaus' *Essentials of Chemistry.*)

9 *Symptoms in carbolic acid poisoning:* Buccal mucous membrane is whitened and hardened; vomiting; burning pain in mouth, esophagus, and stomach; pulse and body temperature are lowered; the pupils are contracted; collapse, and finally death. The urine may become dark. The following symptoms indicate over-absorption of carbolic acid (from a surgical dressing): The urine becomes of a smoky or greenish or black color, and is apt to contain albumin; the temperature becomes subnormal, the respirations and pulse feeble; this is followed by muscular weakness and vertigo.

10. *Symptoms of cumulative effect of digitalis:* Weak, dicrotic pulse, perspiration, nausea, vomiting, lowered reflexes, lowered body temperature, vertigo, muscular tremors, lassitude, delirium, stupor.

BACTERIOOGY.

1. See French's "Practice of Medicine" (1910), page 1257.

2. To demonstrate the existence of *tubercle bacilli* in the sputum: The sputum must be recent, free from particles of food or other foreign matter; select a cheesy-looking nodule and smear it on a slide, making the smear as thin as possible. Then cover it with some carbolfuchsin and let it steam over a small flame for about two minutes, care being taken that it does not boil. Wash it thoroughly in water and then decolorize by immersing it in a solution of any dilute mineral acid for about a minute. Then make a contrast stain with solution of Loeffler's methylene blue for about a minute; wash it again and examine with oil immersion lens. The tubercle bacilli will appear as thin red rods, while all other bacteria will appear blue.

3. See French's "Practice of Medicine" (1910), page 1264.

4. A bacterial vaccine is an emulsion of dead cultures of specific bacteria in a saline solution.

5. Bacteria multiply by fission. A bacterium about to divide seems to be larger than normal, and if it is a coccus it becomes more ovoid; changes occur first in the nucleus, and the bacterium just falls in two. Cocci may divide in one, two, or three directions of space; bacilli divide transversely to their long axis, and spirilla divide transversely to their long diameter.

6. *To distinguish the typhoid bacillus from the colon bacillus:* (1) On gelatin plates the colonies of typhoid develop more slowly than those of colon bacillus. (2) The colon bacillus causes fermentation with production of gas in media which contain sugar; the typhoid bacillus does not. (3) The colon bacillus produces a strong acid reaction and coagulates milk within twenty-four to forty-eight hours; the typhoid bacillus does not coagulate milk. (4) In peptone solution the colon bacillus produces indol; the typhoid bacillus does not. (5) The typhoid bacillus gives the Widal reaction with typhoid serum; the colon bacillus does not.

7. A sterile swab is rubbed over any visible membrane on the tonsils or throat, and is then immediately passed over the surface of the serum in a culture tube. The tube of culture, thus inoculated, is placed in an incubator at 37° C. for about twelve hours, when it is ready for examination. A sterile platinum wire is inserted into the culture tube, and a number of colonies of a whitish color are removed by it and placed on a clean cover slip and smeared over its surface. The smear is allowed to dry, is passed two or three times through a flame to fix the bacteria, and is then covered for about five or six minutes with a Loeffler's methylene-blue solution. The cover slip is then rinsed in clean water, dried, and mounted. The bacilli of diphtheria appear as short, thick rods with rounded ends; irregular forms are characteristic of this bacillus, and the staining will appear pronounced in some parts of the bacilli and deficient in other parts. *Methods of culture:* The bacillus of diphtheria grows upon all the ordinary culture media, and can be readily obtained in pure culture. Loeffler's blood serum, particularly with the addition of a little glucose, is an admirable medium for the rapid growth of this bacillus. The medium should be alkaline and not less than 20° C. *Method of staining:* It stains with any aqueous solution of an aniline dye, and quite characteristically with Loeffler's alkaline methylene blue. Neisser's stain is also recognized. The bacilli also stain well by Gram's method.

8. See French's "Practice of Medicine" (1910), page 324; or Osler's "Practice of Medicine" (1909), page 138.

9. *Bacteria most commonly found in suppurative processes: Staphylococcus pyogenes aureus, Staphylococcus pyogenes albus, Staphylococcus pyogenes citreus, Strepto-*

coccus pyogenes, Streptococcus erysipelatis, typhoid bacillus, gonococcus, tubercle bacillus.

10. The *Bacillus anthracis* is a large, rod-shaped microorganism, with slightly thickened ends; it is from 5 to 20 mikrons in length, and a little more than one mikron in breadth; it has a tendency to form long threads; it is nonmotile and nonflagellated; it is aërobic, and stains by all the alkaline aniline dyes and by Gram's method.

PATHOLOGY.

1. The object is first placed in some fixing fluid, then it is washed, then hardened by immersion in alcohol, then treated with some clearing agent, then placed in paraffin; it is then ready for the section cutter. After the sections are cut the next process is staining, after which the object is ready for examination.

2. See French's "Practice of Medicine" (1910), page 342

3. *Carcinoma* is apt to occur at a later age; is found in structures derived from the epiblast or hypoblast; possesses a fibrous stroma, in which are found both blood-vessels and lymphatics; metastasis is by the lymphatics.

Sarcoma is apt to occur earlier; is found in structures derived from the mesoblast; there is no stroma between the cells; the blood-vessels are in direct contact with the tumor cells; there are no lymphatics; metastasis is by the blood-vessels.

4. See French's "Practice of Medicine" (1910), page 562; or Osler's "Practice of Medicine" (1909), page 768.

5. See French's "Practice of Medicine" (1910), page 1095; or Osler's "Practice of Medicine (1909), page 943

6. See French's "Practice of Medicine" (1910), page 543; or Osler's "Practice of Medicine" (1909), page 751.

7. See French's "Practice of Medicine" (1910), pages 36 and 33.

8. See French's "Practice of Medicine" (1910), page 799; or Osler's "Practice of Medicine" (1909), page 506.

9. Local infections are such as are confined to a part, and are characterized by profound intoxication.

10. *Anemia* is a condition in which the blood is reduced either in quantity or in number of red cells, or in amount of hemoglobin.

Hyperemia is excess of blood in a part of the body.

Immunity is the power of resistance of cells and tissues to the action of pathogenic bacteria. Immunity may be either natural or acquired.

PRACTICE OF MEDICINE.

1. See French's "Practice of Medicine" (1910), pages 1031 and 1032; or Osler's "Practice of Medicine" (1909), pages 1039 and 1040.

2. See French's "Practice of Medicine" (1910), pages 521 and 523; or Osler's "Practice of Medicine" (1909), pages 721 and 730.

3. See French's "Practice of Medicine" (1910), pages 845 and 847; or Osler's "Practice of Medicine" (1909), pages 558, 561, and 562.

4. See French's "Practice of Medicine" (1910), pages 133 and 137; or Osler's "Practice of Medicine" (1909), pages 153 and 155.

5. See French's "Practice of Medicine" (1910), pages 881, 882, and 886; or Osler's "Practice of Medicine" (1909), pages 580, 582, and 591.

6. By *vocal fremitus* is meant a vibration felt on the surface of the chest when the patient speaks. It is *increased* in lobar pneumonia, phthisis, and bronchopneumonia; *decreased* in pleural effusions, emphysema, collapse of the lung, pulmonary edema and tumors.

7. See French's "Practice of Medicine" (1910), pages 672 and 673; or Osler's "Practice of Medicine" (1909), pages 607 and 608.

8. *Organic murmurs* are due to stenosis or incompetency of one or more of the valves of the heart.

Functional murmurs are not due to valvular disease.

Organic murmurs may be systolic or diastolic; may be accompanied by marked dilatation or hypertrophy, and there will probably be a history of rheumatism or of some other disease capable of producing endocarditis. Whereas a murmur, usually systolic, soft, and blowing, heard best over the pulmonic area, associated with evidences of chlorosis or anemia, and affected by the position of the patient, is a *hemic* or *functional* murmur, and denotes as a rule an impoverished condition of the blood.

9. See French's "Practice of Medicine" (1910), page 1072; or Osler's "Practice of Medicine" (1909), page 918.

10. Belladonna poisoning.

The stomach should be washed out; strong coffee may be given; the patient should be kept awake; stimulants, pilocarpine, and artificial respiration are also indicated.

I. OBSTETRICS.

PRIMIPARA.	MULTIPARA.
The fourchet is present.	The fourchet is missing.
The perineum is tense and deep.	The perineum is relaxed and probably torn.
The labia are in apposition.	The vulva is frequently patulous.
The vagina possesses tonicity, and is rough and rugous, with a granular feel.	The vagina is relaxed and smooth.
The cervix is long, soft, and conical; the os is undilated.	The cervix is large, cylindrical, short, not so soft, and probably lacerated; the os is patulous.
The abdomen is full, rounded, tense, and resisting to the touch.	The abdominal walls are relaxed and non-resisting to the touch; the skin is loose and wrinkled.
Dark, purplish-red striæ appear late in pregnancy.	The striæ may be both white and livid, the former being present from the beginning of pregnancy.
The breasts are full, firm, and sensitive to pressure.	The breasts are flabby, pendulous, and non-sensitive to pressure.
The nipples are usually small and undeveloped or even inverted.	The nipples are large and well developed.
Striæ are absent from the breast.	Striæ are frequently to be found.

—(From Dorland's *Obstetrics.*)

2. *Use of the bag of waters:* (*a*) *During Pregnancy:* (1) As a protection to the fetus against pressure and shocks from without. (2) As a protection to the uterus from excessive fetal movements. (3) It distends the uterus, and thus allows for the growth and movements of the fetus. (4) It receives the excretions of the fetus. (5) It surrounds the fetus with a medium of equable temperature, and serves to prevent loss of heat (6) It prevents the formation of adhesions between the fetus and the walls of the amniotic sac. (7) It has been supposed, by some, to afford some slight nutrition to the fetus.

(*b*) *During Labor:* It acts as a fluid wedge, and dilates the os uteri and the cervix; it also slightly lubricates the parts.

See Williams' "Obstetrics" (1909), page 313.

3. See Williams' "Obstetrics" (1909), pages 664 and 477.

4. See Williams' "Obstetrics" (1909), page 842; or Hirst's "Obstetrics" (1909), page 625.

5. See Williams' "Obstetrics" (1909), page 317; or Hirst's "Obstetrics" (1909), page 335.

6. *Positive signs of pregnancy:* (1) Hearing the fetal heart sound; (2) active movement of the fetus; (3) ballottement; (4) outlining the fetus in whole or part by palpation; and (5) the umbilical or funic souffle.

Doubtful signs of pregnancy: (1) Progressive enlargement of the uterus; (2) Hegar's sign; (3) Braxton Hick's sign; (4) uterine murmur; (5) cessation of menstruation; (6) changes in the breasts; (7) discoloration of the vagina and cervix; (8) pigmentation and striæ; (9) morning sickness.

Subjective signs of pregnancy, in the order of their appearance, are: Cessation of menstruation, morning sickness, increased frequency of urination, active fetal movements.

Objective signs of pregnancy, in the order of their appearance, are: Softening of the cervix, changes in the mammary glands, discoloration of the vulva and vagina, pulsation in the vaginal vault, Hegar's sign, active fetal movements, ballottement, palpation of the fetus, intermittent uterine contractions, hearing the fetal heartbeat, rate of growth of the uterine tumor.

GENITOURINARY SURGERY AND DERMATOLOGY.

1. The following table (from Eisendrath's *Surgical Diagnosis*) gives the diagnosis:

TINEA TONSURANS.	ALOPECIA AREATA.
1. Slow and insidious onset.	1. Rapid onset.
2. Patches are—	2. Patches are—
(*a*) Covered with "broken-off stumps."	(*a*) Totally devoid of hair.
(*b*) More or less reddened.	(*b*) Pale and whitish.
(*c*) Rough and scaly.	(*c*) Smooth and soft.
(*d*) Follicles prominent; goose-flesh appearance.	(*d*) Follicles contracted.
3. Fungus present.	3. Absence of fungus.
4. Occurs almost exclusively in children.	4. Common in adolescence and adult life.

—(Schamberg.)

COMA FROM INTRACRANIAL INJURY.	APOPLECTIC COMA.	UREMIC COMA.	ALCOHOLIC COMA.	OPIUM POISONING.
Deep coma; may have history of onset after fall or injury. Evidence of fracture of vertex or base.	Deep coma; sudden onset. If any injury, only a scalp wound.	Deep coma. Slow onset unless convulsions have preceded the coma.	Can be aroused by supraorbital pressure unless very profound.	Can be aroused unless very deep.
Pupil dilated on side of lesion Choked disc.	Pupils unequal or dilated. Contracted in hemorrhage into the pons.	Albuminuric retinitis.	Pupils normal or somewhat dilated.	Pupils contracted to pinpoint size.
Pulse very slow.	Pulse full and slow, often arteriosclerotic high-tension pulse.	Pulse rapid.	Pulse more rapid than normal and full.	Pulse rapid, may be irregular.
Respiration slow and stertorous.	Respiration slow and irregular.	Respiration, frequent and irregular.	Regular respiration.	Respiration very slow —may be 6 to 8 per minute.
Temperature higher —101°.	Temperature higher on paralyzed side, but lower in rectum.		May be low or normal.	
Urine normal or contains trace of albumin.	Urine contains trace of albumin, but may be same as in uremia.	Urine shows albumin, casts, and low urea percentage.	Normal.	Normal.
Hemiplegia on opposite side to that of injury. If contusion of brain is also present, may have generalized convulsions.	Hemiplegia with convulsions on one side.			

2. See Rose and Carless' "Surgery" (1908, page 1178; or Da Costa's "Surgery" (1908), page 1111.

3. The usual symptoms are a very slight discharge, with the passage of shreds in the urine. The discharge is most noticeable in the morning; the shreds are composed of epithelium and a few pus cells sometimes containing gonococci. The treatment consists in stretching the urethra with sounds, followed by irrigation with some mild antiseptic solution. Astringent injections of solution of sulphate of zinc, potassium permanganate, etc., are advisable. If any unusual patches are discovered on examination with the urethroscope they should be brushed with nitrate of silver (gr. 20-℥j). Internally santal oil or balsam of copaiba will be found useful.

4. See Rose and Carless' "Surgery" (1908), page 1272.

5. See Rose and Carless' "Surgery" (1908), page 1275.

6. See French's "Practice of Medicine" (1910), page 409; or Osler's "Practice of Medicine" (1909), page 359.

7. *Erythema hyperamicum* is a form of erythema in which there is redness of the skin but no swelling and usually no subsequent desquamation.

8. See Rose and Carless' "Surgery" (1908), page 309; Da Costa's "Surgery" (1908), page 1057.

7. *Salvarsan,* also called arsenobenzol, "Ehrlich-Hata," or 606.

It is a bright yellow powder, slowly soluble in water, has an acid reaction, contains about 34 per cent. of arsenic, is used in the treatment of syphilis, but is in the experimental stage only. It would be well not to give up the older remedies yet, and not to believe all the newspaper reports on this remedy. Up to the present it seems to be uncertain whether to use the substance in a solution or in an emulsion, also whether it should be administered into a muscle, into a vein, or under the skin. Further, there are certain contraindications; and bad results have followed its use (or abuse).

Influence of Starvation and Potassium Iodide upon the Suprarenals.—Vernulet and Dmitrowsky found that in rabbits starvation is associated with a disappearance of the chromaffin substance of the suprarenals and that potassium iodide inhibits the action of the suprarenal secretion. The latter fact probably explains the property possessed by potassium iodide of diminishing blood pressure and its therapeutic value in arteriosclerosis.—*Archiv für Experimentelle Pathologie und Pharmakologie.*

Early Diagnosis of Cancer of the Uterus.—Armand Siredey states that the symptons generally considered diagnostic in cancer of the uterus, pain, fetid discharge, and hemorrhage, do not appear in the beginning of the disease, but only when it has advanced to the period of ulceration. The pain in the early stages is of the character that is met with in metritis, heavy, located in the lumbar region, and extending to the legs and pelvis. The lancinating neuralgic pains begin only when the tissue outside of the uterus containing the nerves become involved. The discharge is like ordinary leucorrhea, without the fetor that is expected until the late stages of necrosis of the growth. The symptom of hemorrhage varies much with the type and location of the growth. Hemorrhage that is repeated in the intermenstrual stage is of more value than excessive flow at the menstrual period. Extreme fetor is more apt to occur in senile metritis, due to the action of anaerobic bacteria. The only really accurate method of diagnosis is curettement and examination of the scrapings. The author advocates dilatation of the cervix, and such examination in every case of suspected cancer of the fundus.—*Le Bulletin Médical*

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Sixty-second Annual Meeting, Held at Los Angeles, Cal., June 26, 27, 28, 29, and 30, 1911.

(Special Report by Telegraph to the MEDICAL RECORD.)

HOUSE OF DELEGATES.

Monday, June 26—First Day.

DR. WILLIAM H. WELCH OF BALTIMORE, PRESIDENT, IN THE CHAIR.

President's Address.—Dr. WILLIAM H. WELCH, after calling the meeting to order, said, among other things, that the creation of the House of Delegates was one of the greatest improvements that had been brought about in the history of the association. The transaction of business had been made much easier and the fact that it was now possible for all manner of things to gain a hearing carried greater possibilities both for evil and for good. This implied a larger responsibility. Too much emphasis could not be laid on the duty of sections to select the best and wisest men as represented in the House of Delegates and these in turn should be willing to assume their share of responsibility and should select for their activities such lines of work as were of broad national interest, such lines as offered the greatest possibility of obtaining the very best results with the resources and means at hand, and they should avoid duplication of works. The methods most appropriate for the association to follow and best calculated for a thorough study of the conditions and remedies were to be found in the reports of conferences and pamphlets as set forth in the work of the association. It was customary for the president to review the work of the association and to point out important matters requiring action. The former of these would be brought to notice in the reports presented, and in regard to the latter he wished to suggest the following: First, as president he had received a letter from Major Davis, president of the American Red Cross Society, requesting that a committee from the American Medical Association be appointed to consult with a committee from the Red Cross Society as to the best methods to follow in times of distress or disaster. Dr. Welch submitted this letter and expressed the hope that the House of Delegates would take action on it. Secondly, he wished to call their attention to a suggestion made by the late Dr. Ellis of Maryland that in connection with the exhibition in celebration of the completion of the Panama Canal there should be a fitting celebration of the triumphant solution of the sanitary problems connected with the completion of the canal as no less wonderful or less important than the achievements of engineering. Dr. Welch thought that an international congress of tropical medicine would be a fitting way of bringing these sanitary achievements to the notice they deserved and recommended the appointment of a committee to make arrangements for such a congress and for the appropriation of funds for the maintenance of this desired end.

Report of the General Secretary.—DR. GEORGE H. SIMMONS of Chicago submitted this report which showed that the membership of the American Medical Association on May 1, 1910, was 34,176; on May 1, 1911, it was 33,960; a net loss for the year of 216. This loss was due to the fact that until last year continued efforts were made to get those who were taking the Journal as subscribers and who were eligible for membership in the association to have their names transferred to the rolls. For the past year they had made repeated efforts in this direction on account of the uncertainty of the final ruling of the Post Office Department regarding the mailing of the Journal to members as such. The total membership of the component State associations was 71,118, an increase over the number reported in 1910 of 972. The secretary made an urgent appeal for the adoption of a plan for the transfer of membership from one component society to another, in any State, and for a uniform system of recording membership in the various States. Another matter which deserved careful consideration was in regard to the Judicial Council. Questions of an ethical nature were constantly presenting themselves to the association and this led to the appointment of a Judicial Council in 1874. It was presumed that this council would hold meetings between the sessions of the association but no such meetings were held. The chairman of the council a few years ago reported to the House of Delegates that it was almost impossible for a case to reach the Judicial Council because of the difficulty of getting a quorum at an annual meeting. Need for such a council was greater to-day than ever before, as, with the exception of one or two States, there was no control of membership by either the State or the American Medical Association. The questions of secret division of fees, contract practice, advertising, etc., should be met and given careful consideration. The secretary, therefore, urged that the Judicial Council be reelected; that its functions be broadened; that it adopt such methods of procedure as it deemed best, with the approval of the House of Delegates; that the secretary of the association should be *ex officio* secretary of this council; and that the trustees be requested to appropriate the funds necessary to defray the expenses of the members of this council going to their meetings.

Report of the Board of Trustees.—Dr. M. L. HARRIS of Chicago presented this report in which he announced that the association had moved into its new building in January. This building was a model of construction and as perfect in its appointments as it was possible to make it. The prosperity which was theirs increased their responsibilities and these rested not only on officers of the association and on committees but also on every member of the House of Delegates. These responsibilities did not cease with the adjournment of the annual session. Resolutions passed by the House of Delegates would do little good unless members carried home the spirit and intent contained therein and labored in local societies until they were read and approved by every individual member throughout the land. It was the duty of this body to consider carefully all questions which had a material bearing on the welfare of the profession and of the people along health lines and sufficient time should be devoted to them so that conclusions reached would show that they were the result of mature deliberation. The trustees recommended a discussion as to what regulations governing membership in this association should be adopted and they recommended that the by-laws be amended so as to admit of the appointment of a Judicial Council such as was needed. The regular weekly issue of the *Journal of the American Medical Association* averaged 56,523 copies and the total number of copies issued during the year was 2,905,726. The *Archives of Internal Medicine* had a circulation of 2,133, which was satisfactory, considering the technical character of the publication. The *American Journal of Diseases of Children* was first issued in January, 1911, and on June 1 had a paid circulation of over 1,600.

Report of the Treasurer.—Dr. FRANK BILLINGS of Chicago submitted this report which showed that the value of the plant and property of the association was $288,833, and the surplus, $148,529, an increase of $51,994 over the previous year. The accounts had been audited and the auditors reported that the accounts were kept in a careful and efficient manner.

Report of Council on Health and Public Instruction.

—Dr. Henry B. Favill of Chicago made a report for this council, which was created at the 1910 session. He considered the work of the council under two heads: 1, the work of the various bureaus subordinate to the council; 2, the work of various subcommittees subordinate to the council. He first spoke of the organization work of the council which had been done as heretofore by Dr. J. N. McCormack, who during the year had visited ninety-seven cities in eleven States and had delivered addresses in each. The value of these meetings in educating the public sentiment was becoming more apparent every year. The council was considering the advisability of putting a number of speakers in the field as the work was too great for one man. (2) *Bureau on Protection of Medical Research:* This bureau had continued the publication of articles and pamphlets giving reliable information regarding animal experimentation. During the past year the following pamphlets had been published: "Animal Experimentation in Relation to Practical Medical Knowledge of the Circulation," by Joseph Erlanger; "The Relation of Animal Experimentation to Our Knowledge of the Plague," by Geo. W. McCoy; "Medical Control of Vivisection," by Walter B. Cannon; "Immunolgy, a Medical Science Developed Through Animal Experimentation," by Frederick P. Gay; and a number of others. The plan of the bureau to control laboratory procedures in a manner satisfactory to the people by regulations adopted by the corporate bodies, which included the laboratory workers, had been given wide publicity during the year. (3) *The Bureau of Medical Legislation:* What work this bureau had done had been done without the advantage that might have accrued from the work of a special committee created for the purpose of formulating a bill for the organization of Federal health work, services which would receive the unqualified support of all interested in the conservation and improvement of the public health. However, the sixty-first annual Congress has adjourned without anything having been accomplished, but fortunately no obstructive legislation was enacted. The Congress now in special session was not taking up any general legislation. This bureau also reported the legislation that had been secured in the various States during the past year. The council had cooperated with tate legislative committees, sending them information and material whenever requested. Attorneys for the association had prepared an exhaustive brief on "chiropractice." This contained an argument based on Supreme Court decisions to the effect that "chiropractice" was the practice of medicine and that followers of this cult were amenable to medical practice laws. The compilation of Supreme Court decisions on medical practice acts had been practically completed and was in the hands of the printer. They now proposed to prepare a digest of over 300 Supreme Court decisions for the guidance and assistance of officers of medical examining and licensing boards and a similar volume of public health laws. (4) *Bureau of Public Health:* This bureau had taken up no new work as yet. (5) *Bureau of Public Instruction*: Probably the most important line of work taken up by the council had been the preparation and distribution of regular bulletins to the newspapers of the country on public health matters. The mailing list to which these bulletins were sent regularly numbered 4,818 publications. The most gratifying feature of press bulletin service was the readiness with which editors had utilized material sent to them. In sending out pamphlets they had endeavored to cooperate with State boards of health so as to avoid duplication of work. As a means of effective cooperation the council had under consideration the preparation of a standard series of public health pamphlets to be printed in the association office and to be supplied to State and municipal boards of health, philanthropic organizations, etc., free of cost. 2, Reports of Subordinate Committees: Dr. Favill said that, in addition to the above, the council wished to present reports of chairmen of committees which had been placed under the council. The report of the Public Health Education Committee, of which Dr. Rosalie S. Morton was chairman, reviewed the education work done by men and women physicians throughout the country. Last year they reported 2,250 lectures given to 102,575 people; this year over 2,800 lectures had been given to 230,600. Beside the educational work valuable work in the prevention of disease had been done along other lines. The physicians who were selected to give lectures were selected by their county medical societies or State health officers and 1,800 members of the American Medical Association had assisted in giving lectures. This report also referred to help that the committee had rendered other organizations which were working in the interest of public health.

Report of Committee on Uniform Regulation of Membership.—The report of this committee reviewed its efforts made in the past to secure uniform provisions regarding membership and again set forth reasons why this was desirable. It was the experience of the committee that this work could not be done by correspondence or by attempts to modify the by-laws or frame recommendations during the rush of an annual session, and they recommended that the present committee be continued or another appointed, and that the trustees be requested to appropriate a sufficient amount to enable it to hold the meetings at the headquarters of the association in Chicago, and that they present, if possible, to the House of Delegates at the next annual meeting a complete plan regarding the regulation of membership throughout the entire organization.

Report of the Director of Post-Graduate Study.—Dr. John H. Blackburn presented to the council this report, in which it was stated that the plan in operation would be continued. The increase in the number of societies taking this work and in the interest taken was rather more marked during the first three years than during the last. The cause of failure to get the usual number of new societies to take up this work was probably because Dr. McCormack had been unable to visit as many societies as had been his custom.

Report of Committee on Visual Standards for Pilots.—This committee, of which William Campbell Posey was chairman, reported to the council that they had conferred with the Department of Commerce and Labor with the view of obtaining the adoption of suitable standards for the examination of the eyes of navigators operating under Federal law, and that after conference with the secretary of the department, at which the Board of Supervising Inspectors of Steamboat Inspection Service were present, the Department of Commerce and Labor had adopted the recommendations of this committee with one slight modification, and that after July 1 of this year all navigators under control of the department would be examined by standards which this committee submitted to them. Standards were determined on after careful study of foreign standards and after due consideration of the minimum degree of vision a candidate might have and yet be a safe pilot under all conditions of weather. It was desired of this committee that it be continued for another year for the purpose of obtaining, if possible, the enactment of proper Federal or State laws to control the examination of large numbers of navigators who still continued to ply their vocation without adequate test of visual and aural capacity.

Report of Committee on Prevention of Blindness.—This committee, of which Dr. F. Park Lewis of Buffalo was chairman, reported that they had done their work by the appointment of a series of subcommittees on ophthalmia neonatorum, toxic amblyopia, wood alcohol am-

blyopia, trachoma, congenital blindness, hygiene of eyes, and industrial conditions affecting the eye. The most important movement during the past year for the prevention of blindness and the conservation of vision was held under the auspices of the Russell Sage Foundation in December, 1910, when a national association was formed. In order that the work, which was so rapidly progressing under the various State commissions, associations, health boards, and other bodies, might be crystallized into one effective effort, this committee proposed that a special day in October, 1913, be chosen as a "conservation of vision day," and that then all these forces be combined in emphasizing the practicability and importance of sight saving. Such a movement would fix the attention on the various phases of unnecessary blindness, and there should be actual demonstrations of the best methods of lighting homes, schoolrooms, and workrooms. The committee recommended that the work as outlined by the subcommittees be continued, and that the American Medical Association Committee on Hygiene and Sanitation approve of a uniform law for the control of ophthalmia neonatorum, and that its enforcement be urged on health authorities in every State and city in the country. The report of the subcommittee on ophthalmia neonatorum stated that in Indiana and Dakota laws had been enacted which made any claim on the mother illegal unless the question, whether or not a prophylactic had been used, had been answered by the attendants. The law seemed to be objectionable because it deprived the attendant of remuneration for services performed as a penalty for neglect of another duty which he had omitted. It would seem better that the reporting of births and of existing cases of ophthalmia neonatorum be required by law under penalty, and that if failure to observe the requirements of the law were rigidly prosecuted and the results widely published it would place departments of health in a position to take right measures for the protection of babies' eyes at the right time. The report of the subcommittee on the toxic amblyopias, exclusive of methyl alcohol, showed that the committee had made very extensive investigations as to the frequency of this condition in America. The literature pertaining to this project from January, 1904, to August, 1910, revealed 249 references. Of these 249 references 211 were general, that was to say, they discussed the toxic action of various poisons on the human system without specific record of ocular complications, and 38 were direct references, that was to say, those which were limited to a discussion of the effect of toxic agents on the visual apparatus. The comparatively small number of cases reported did not give any adequate idea of the frequency of amblyopia in this country, but did give an idea of the substances which most frequently caused this condition. The most frequent cause of toxic amblyopia was ethyl alcohol or some substance in which ethyl alcohol was the active agent. Other causes operating occasionally were lead, quinine, antipyrine, iodoform, formaldehyde, coffee, and salicylate of sodium. Reports from eleven hospitals extending over a period of six years among a total of 471,975 patients showed that 523 had sought relief from visual defects depending on the action of some toxic substance. But these reports did not indicate what toxic substance was responsible. There were no available statistics showing the number of cases treated in private practice, but it was the conviction of the committee that there were many more than was generally supposed. The committee closed its report with an appeal to those having charge of hospital statistics to make an endeavor to increase the accuracy of hospital records. The report of the subcommittee on blindness produced by the ingestion of methyl or wood alcohol, after showing the harmful effects of this substance and its very extensive use in commercial products used in manufacture, asked that it be continued in order that further investigations might be made to inquire the reasons for partial failure to accept denatured alcohol as a substitute for poisonous wood alcohol; to devise ways and means for the removal of obstacles to the general use of denatured alcohol; to enforce the use of the poison label on all retail packages of wood alcohol, and to disseminate a wider knowledge of the poisonous character of every form of methyl alcohol; and, finally, to procure such legislation as would prohibit the manufacture or sale of every form of purified or deodorized methyl alcohol. The report of the Subcommittee on Blindness from Trachoma called attention to trachoma as an alien disease. They might gain some idea of the probable annual importation of trachoma prior to 1897, when laws to prevent its entry became effective, from the annual reports of 1910 of the Commissioner-General of Immigration, which showed that 6,400 persons with trachoma were debarred from embarking and 2,600 were debarred from landing and were deported. There were localities in the United States where this disease was endemic. After considering efforts, social and legislative, directed against trachoma the committee suggested that those States in which this disease was endemic should follow the example of New York and establish trachoma dispensaries in different parts of the State and a centrally located trachoma hospital. The subcommittee on congenital blindness submitted a preliminary report, based on a review of the literature, and from statistics collected it might be said that 5 per cent. of all blind persons suffered from some form of congenital blindness. If the number of cases reported was taken as a standard by which to judge the relative frequency of the occurrence of each lesion the list would be headed by microphthalmus, followed closely by aniridia and by coloboma of the iris. Anophthalmus and the different forms of cataract also ranked high. Most infrequent were the tumors, especially the teratomas. The report of the subcommittee on hygiene of the eyes showed that they had decided on a definite plan of procedure, and with the cooperation of the Illuminating Engineering Society and several large electric and gas illuminating companies they would study the effect of various forms of artificial illumination. The actual work of investigation would be begun early in the autumn. The reports of the subcommittee on industrial conditions had limited their investigations to the consideration of common accidents which were preventable; to accidents occurring while handling high explosives; accidents due to bursting locomotive oil and water gauges; accidents due to scalds, caustics, or exposure to irritating fumes; diseases due to excessive light; and diseases due to occupations requiring prolonged and peculiar use of the eyes; and then discussed the prophylactic measures and methods of securing the interest of the public and the cooperation of the employer and employee in applying such measures.

Report of the Council on Medical Education.—Dr. Arthur Dean Bevan of Chicago submitted a report in which he called attention to the annual conferences of the Council on Medical Education which had been held every year since 1904, which were largely attended by members of State licensing boards, deans of medical schools, presidents of universities, and other prominent educators. This work had been effective in bringing about rapid and marked improvement in medical education during the past seven years. Among these advances were: (1) The number of medical schools in the United States had been reduced from 166 in 1904 to 129 in 1911. This reduction had been due to closing of poor schools or to merger of two or more colleges, forming in each instance one invariably stronger and better medical school. (2) Medical schools requiring one or more years of collegiate work for admission had been increased from four

in 1904 to 42 in 1911. (3) Although the number of medical students in the United States had been reduced from 28,142 in 1904 to 21,526 in 1910, on the other hand the number of students enrolled in higher standard medical colleges had increased from 728 in 1904 to 4,230 in 1910. (4) In 1904 only 2.4 per cent. of all medical colleges were requiring one or more years of college work for admission, now 32.6 per cent. of all colleges were requiring that preparation. (5) Since 1904 preliminary educational requirements had been adopted in sixteen more States; a four year high school education had been made the standard in twenty more States, and nine States had adopted as their minimum requirement one or two years of college work. (6) Six State licensing boards were now to a limited extent using practical tests in their State license examinations. (7) Since 1904 reciprocal relations had been established by nine more States, making a total of thirty-six which now had such relations with other States. After pointing out advances still needed the council made the following definite recommendations: (1) Men best qualified for the work should be urged for appointment on State licensing boards. (2) The public and educators should be educated regarding the necessity of a single portal of entry to the practice of medicine for the right to treat human ailments by whatever methods. (3) The need of private endowment or State aid for medical education should be emphasized. (4) For medical colleges they recommended the adoption at earliest possible time of one or two years devoted to physics, chemistry, biology, and modern languages, in addition to four years' high school education. (5) The securing of more expert full time instructors, particularly of the laboratory branches. (6) The development of better library and museum facilities. (7) The development of more extended and careful study by senior students of patients in dispensaries and hospitals. (8) The adoption at the earliest possible moment of a fifth year to be spent by the student as an intern in a good hospital. (9) They recommend for State licensing boards the adoption of the requirement that each applicant should possess the higher preliminary qualifications as outlined above. (10) The provision for a more careful valuation of the preliminary credentials presented by all applicants. (11) The adoption of thorough and practical tests at State license examinations. These were now employed by England, Germany, Hungary, Norway, and other leading countries of Europe. (12) The extension of reciprocal relations with other States, but this provision should be safeguarded by a careful scrutiny of the applicant's credentials and by more strict use of the boards' discretionary powers. This committee also called attention to the too high percentage of failures on the part of graduates from certain localities, when they took examinations in States other than those in which they had graduated. Illinois, Kansas, Maryland, and Tennessee were distinctly localities responsible for the worst medical schools. If they continued to make progress during the next eight or ten years as rapidly as they had during the past seven years the standard of medical education in this country would be equal to that of any other country in the world.

Dr. WELCH congratulated the Council on Medical Education on the work they had done. This work had been of a very delicate nature and it was also a marvel of thorough investigation. The publicity given this work had impressed every one with its possibilities for good. The methods pursued were worthy of commendation.

Report of Committee on Scientific Research.—This committee, of which Dr. ALFRED STENGEL was chairman, reported that it had made for the current year four grants of $200 each for work to be reported at the present meeting as follows: (1) Dr. R. M. Pearce of Philadelphia for "Studies on Experimental Blood Infection," by H. T. Karsner and J. H. Austin; "The Relation of Toxic Doses of Horse Serum to the Protective Dose of Atropine in Anaphylaxis," by H. T. Karsner and J. B. Nutt. (2) A grant to Dr. E. C. Rosenow of Chicago for work on "Autolysis of Pneumococci." (3) A grant to Mary Rawley Lawson of Boston for work on the "Development of the Tertian Malarial Organism." (4) A grant to Dr. Karl K. Koesser of Chicago for work on "Antibodies in Scarlet Fever."

Report of Committee on Scientific Exhibit.—Dr. FRANK B. WYNN of Chicago in this report stated that there was a fallacy prevalent to the effect that only large exhibits would be acceptable; small ones were equally desirable and sometimes more instructive. The committee suggested that the work done by public health exhibits which they had initiated had been so effective that the time seemed ripe for the infusion of health problems into novels and plays and they proposed to have a play next year presented as a part of the scientific exhibit.

Report of the Committee on Nomenclature and Classification of Diseases.—This committee, of which Dr. FRANK P. FOSTER of New York was chairman, reported that they had been favorably impressed with the Bellevue Hospital nomenclature of diseases and conditions which first appeared in 1903, and had since been twice revised. They recommended that this system of nomenclature be made a part of whatever publication on the subject the American Medical Association might decide to issue. They thought it would be well to publish also a Latin list, if only for the purposes of international correspondence. It might be well for the American Medical Association to provide for cooperative work with the profession in other countries to the end that they might eventually have a uniform nomenclature and classification.

Report of the Committee on Memorial to Medical Officers Who Died in the Civil War.—This committee, of which Dr. WILLIAM C. GORGAS was chairman, reported progress and proposed to appeal in the near future to the several State medical societies for their influence and material help in the erection of this monument, and perhaps subsequently to Congress. They recommended that the committee be continued with the same privileges and appropriations that were authorized at the Atlantic City meeting in 1909.

Report of Committee on Relief Fund and Physicians' Sanatorium.—This committee, of which Dr. Edward Jackson of Denver was chairman, reported that after a thorough discussion of the subject they would recommend the following: (1) That the House of Delegates endorse the proposition to organize a corporation for the collection and administration of a fund to be used as a relief fund and to support a tuberculosis sanatorium, which should be located in an elevated region of the United States west of the hundredth meridian of logitude. (2) That a committee of five be appointed with authority to add to their number one member from each State society and from the government medical services to bring the subject before local societies, to receive money, and to pay it to the designated custodian. (3) They recommended that the Board of Trustees of the American Medical Association be appointed custodian of funds and that a committee of five be appointed to prepare a plan of incorporation.

Report of Committee on National Health Organization.—Dr. WILLIAM H. WELCH, as chairman of this committee, reported that pursuant to resolutions adopted at the St. Louis meeting he had appointed a committee of seven members which met in New York in March and, after a careful consideration of the situation, the skeleton of a bill for the establishment of a Department of Health was outlined. The committee met on April 1, and appointed a subcommittee to gather information from vari-

ous countries with respect to the national health organizations of each with a view to enabling the committee to perfect its work.

Report of Committee on Davis Memorial.—The secretary read a letter from Dr. H. O. Marcy of Boston, chairman of this committtee, in which he begged that his resignation which he had presented last year might be considered final. As they had not been successful in raising the funds necessary for this memorial he suggested that a memorial letter be issued by State societies and that as the American Medical Association had contributed $5,000 toward this memorial it seemed fitting that the chief hall in the new Association building should be considered as a memorial hall and a bronze bust of Dr. Davis be placed there. All of these reports were referred to the appropriate reference committees appointed by the President of the House of Delegates.

Tuesday, June 27—Second Day.

Report of Reference Committee on Medical Education.—Dr. H. D. Arnold of Massachusetts, in making this report of the work of the Council on Education, said that they felt sure that this work would prove of permanent value. It was most gratifying that Dr. P. J. Eijkman of The Hague had listed the Council of Medical Education among the organizations of the world which were exerting an international influence on the standards of medical education. While the council disclaimed credit for all of the improvements that had come since it began work, others felt that it was to its efforts that improvements were largely due. The increase in the number of students in the high grade schools and the decrease in the number in the poor schools showed that the intelligent medical student was quick to take advantage of the opportunities offered by the high grade medical schools. The committee recommended that the House of Delegates approve of the work done and provide for another inspection of medical schools as soon as this was deemed advisable. They endorsed the suggestion that Mr. Frederick G. Hallet, secretary of the Conjoint Board of Examiners in England, who had done so much to develop the efficiency of that board, be invited to attend the next conference on medical education. It was desirable that public sentiment should be educated as to the needs of reform in the methods of medical licensure and they suggested that cooperation between the Council on Medical Education and that on Health and Public Instruction would prove effective. The chief new feature was that requiring that the student spend a fifth year as intern in a hospital or, in the case of those who expected to enter the field of teaching, one year in the laboratory. It was hoped that the time was not far distant when this requirement could be made mandatory. It was also suggested that cooperation between the Council on Medical Education and that on Pharmacy and Chemistry could be of assistance in finding a solution whereby the time spent in the study of many unused drugs might be reduced or eliminated.

Report of Reference Committee on Legislation and Political Action.—Dr. H. J. Hurty of Indiana, after pointing out how inefficient the Pure Food and Drug Law had proved in view of a recent Supreme Court decision, offered resolutions in the form of a petition asking that this law might be amended so that it would no longer be possible to label articles with false and misleading statements, and providing that a copy should be sent to the President, the Vice-President, the Speaker of the House of Representatives and to each of the Senators.

Reference Committee on Amendments to the Constitution and By-laws.—Dr. A. T. Mc Cormack of Tennessee introduced a resolution providing for the appointment of a Judicial Council to consist of five members which was to have original jurisdiction in all controversies involving questions of ethics in the association itself or its constituent societies; in other cases it should have appellate jurisdiction. This committee offered a resolution amending the by-laws in reference to the admission of associate members. At the 1910 meeting, in amending the by-laws, dentists and pharmacists had been recognized as eligible but scientists had been omitted; this was found to interfere with the work of several of the sections and the by-laws required amendment restoring scientists to the right of associate membership. This amendment was adopted.

Reference Committee on the Reports of Officers.—Dr. G. W. Guthrie of Pennsylvania in accordance with the suggestion made by the president introduced a resolution providing for the appointment of a committee from the American Medical Association to cooperate with a committee from the Red Cross Society, with a view of considering what would be the best methods to employ in times of war. Dr. Guthrie also introduced a resolution providing for the appointment of a committee of seven to formulate plans for the celebration of the completion of the Panama Canal.

Other Resolutions.—In view of the fact that much apparatus used by physicians and laboratory workers had to be imported and in view of the fact that the duty on such articles was unwarrantably high, Dr. R. M. Funkhouser of Missouri presented a resolution that these excessive tariffs be adjusted on a reasonable basis and providing that copies of this resolution be sent to the President and the Sixty-Second Congress now assembled. A resolution was also presented providing for the creation of a section on hospitals and hospital work.

Wednesday, June 28.—Third Day.

The President called a special meeting to dispose of some unfinished business. An announcement of the prize awards was also made and the meeting then adjourned.

GENERAL SESSIONS.

Tuesday, June 27—First Day.

The meeting was opened by an invocation by the Right Reverend Joseph H. Johnson of Los Angeles.

Address of Welcome.—Dr. W. Jarvis Barlow, President of the Los Angeles County Medical Association, welcomed the association in behalf of the local profession. He dwelt particularly on the benefits that accrued to any locality from a meeting of this kind and said that if the leaders realized how great an inspiration their coming had been they would more often choose new localities. The inspiration had affected both lay and medical people. The extent to which it had affected the latter was shown by the fact that the local society had increased its membership by 100 new members during the past year. They felt their separation from teaching centers and thanked the association most heartily for the opportunity its presence afforded.

Dr. Thomas W. Huntington of San Francisco, president of the Medical Society of the State of California, welcomed the association in behalf of the medical profession of the State.

Hon. George Alexander, Mayor of Los Angeles, in his address of welcome, begged physicians not to send patients in the last stages of tuberculosis to California to die unless the patients had the means of being cared for. Many came who went directly to the county hospital and died there in from ten to thirty days. This was imposing an undue burden on the people of California.

Dr. Welch responded to the address of welcome and introduced the President-elect, Dr. John B. Murphy of Chicago.

Address of President.—Dr. Murphy said that it was

the purpose of most men to do something worthy of the recognition and appreciation of their fellow-men. He was gratified with the honor conferred upon him. The span of life was so short that many deserving of it could not receive it. In return he would give his best energy, thought, and judgment to the affairs of the association. Dr. Murphy proposed two innovations: the first an experiment inaugurated at this meeting of giving popular lectures with lantern and graphic demonstrations, and the second, of giving clinical demonstrations before and after the meetings. In regard to the first of these, he said that it was not a good economic proposition that they should meet in a place and not leave a lasting impression. Such a course of lectures on health and disease, carefully planned, sustained by lantern demonstrations, photographs, etc., and presented in a simple, comprehensive, and attractive manner, should become a permanent feature of these meetings. As to the second suggestion, that of having clinical days before and after the meeting, Dr. Murphy said that most members devoted a week to the meeting and these days would not involve any loss of time. They would not interfere with the work of the sections, but they would form an attractive, instructive, and inspiring means of advancing, coordinating, and standardizing medical knowledge. This plan had been adopted by the Association of Military Surgeons at the 1910 meeting. An ever-increasing number of practitioners came to clinics and operating ampitheatres in order to familiarize themselves with recent developments in diagnosis and treatment and it should be the aim of these clinics to give recent methods of diagnosis and treatment, but not to lay emphasis on rare cases unless they aided in this general aim. Cases and materials for demonstration could either be furnished at the place of meeting or transported there. Methods of teaching should be particularly emphasized. Dr. Murphy felt sure that this innovation would double the attendance at the meetings. In regard to the question as to how the American Medical Association could be made more serviceable to the profession and to the American people, Dr. Murphy said his first suggestion would be that they should increase their membership and thereby their funds and to do this required the influence of all respectable members of the profession in remote and distant localities as well as in the popular centres. There were at present at least 140,000 medical men in the United States, and at least 100,000 of these should belong to this association. Doubling the membership from 34,000 to 70,000 should not be a difficult matter. There were at least 40,000 men in State societies who should belong to the organization. The association must be active in many diverse ways, direct and indirect. The indirect work of the councils was not appreciated by the average medical man. The fixed charge for the support of the work of these councils should not be decreased, but rather increased in order to advance their efficiency. Dr. Murphy referred to the policy of the Journal in acccepting only clean advertisements and this policy had had an influence on the press throughout the country. By a vigorous advertising policy the Journal might take care of a larger circulation and make a reduced rate for subscriptions. Possible public instruction in medicine was one of the most important functions which the American Medical Association had to perform. The patient was the point about which all medical interest centered. The great question was what was best for him. The profession criticised the public for its employment of quacks, not alone by ignorant foreigners, or the poor and untaught, but by the so-called better classes of educated and seemingly intelligent people. They gave more enthusiastic support to these quacks than to the regular profession because when they treated them they gave some plausible reason for the methods followed, while the regular profession had demanded acceptance in blind faith, and the age of blind faith had passed. What beacon had they set for the layman whereby he might select a physician? The people should be educated in the basic principles of medicine. Articles should be carefully prepared so that they would present subjects in a manner both scientific and clear. The Council of Public Health and Instruction should supply information on the true nature, etiology, transmission, and early signs of disease. If this were done the amount of sickness would be greatly decreased, as the outcome of many diseases depended upon their early recognition. Hitherto the patent medicine almanac, "Leaves of Healing," etc., had been the only instruments furnishing information to the public and in these truth and science were libeled in every line. If the American Medical Association gave the people correct information it would follow them. When they took this course they would get the support that true work always commanded in regard to compensation for physicians. Dr. Murphy said that there were a few of the profession better remunerated than ever before in the history of the world, but the compensation of the average physician was less to-day than it was twenty years ago and in the general average of a large number of physicians less than that of day laborers. The physician had to keep up a standard of efficiency and he could not do this unless he received adequate compensation. If he did not receive a sufficient compensation to buy books and to have sufficient leisure to read them the public suffered. Dr. Murphy advocated a national standard for medical educational institutions and for medical practice acts, corresponding to those of interstate commerce. He also urged legal suppression of incompetent medical colleges. Dr. Murphy referred to the work of the Council on Medical Education and said that this work should receive the moral support of all members of the association. A note of warning should be sounded lest medical education should be too much influenced by faddists. Professors for medical schools were formerly chosen because they had been successful practitioners and for various personal or extraneous reasons, regardless of any special ability to impart knowledge. Many able men had been selected in this way, but they had looked to the university to correct this custom. The era of the university had arrived and the head of a department was usually a man of world-wide fame and reputation; he had accomplished great things in the laboratory, but he was often incapable of imparting information in an acceptable manner even in a third-class school. Original investigators were apt to ride hobbies even in the classroom. The elder faculty of a medical school should be chosen because of special ability to impart knowledge. The laboratory idea had dominated medical education for a decade and a department controlled by purely scientific men without any practical clinical knowledge failed to fill the gap between laboratory and clinical findings. The clinical side of medical education was now receiving more attention and a fifth year added to the course in medical education as an intern in a hospital was now suggested for all, and the opportunity for this was seized by the student whenever possible. A fifth year clinical course should be arranged with more care than any other course. License to practice medicine should be limited to five years, when the individual should be compelled to return to the university for a further course of instruction. Dr. Murphy recommended the establishment of a lay health journal as an additional means of educating the public, and he recommended that the House of Delegates appoint a committee to attend the National Educational Association, which would meet in July in San Francisco. The teachers had been planting the seeds of health knowledge in the minds of the children and they all recognized how important this was and it was fitting that a committee should bear them thanks for this work. Dr.

Murphy heartily approved the plan of proposal to establish a judicial council to deal with ethical questions. He did not think that the medical profession was overcrowded; physicians and surgeons were not in competition with their fellows, but with the medical standard of the time. He who kept above the standard desired companionship. The ideal of the medical profession must be stimulation of individual effort and for each to assist the other in his upward progress. The individual was responsible for his own position and in a limited degree for that of his brother. By superior intelligence, fidelity to purpose and indefatigable labor some had become leaders.

Communication from Senator Owen.—Dr. Geo. H. Simmons read a letter from Senator Owen to the association in which the latter regretted his inability to accept their invitation to address the meeting. He stated that the American Medical Association had not had anything to do with the introduction of the first bill providing for the establishment of a National Department of Health in an official capacity. He referred to the activities of the league for medical freedom and added that he hoped the time would come when some method would be devised of compensating physicians for work in preventive medicine, as the work that they were doing would necessarily lessen the amount of sickness and correspondingly the income of the physician. The maintenance of high ideals was the first duty of the physician; he should present himself to his clinetèle as a fine specimen of humanity, the result of good health and a good life.

SECTION ON MEDICINE.

Tuesday, June 27—First Day.

Dr. Allen A. Jones of Buffalo in the Chair.

Verruga Peruana or Carrion's Disease.—Dr. H. A. Giltner, U. S. N., said that verruga peruana was an inoculable disease epidemic in certain districts of Peru. It was characterized by slow onset, fever, muscular and arthritic pains, profound anemia, and a peculiar sarcomatous eruption showing a strong tendency to hemorrhage. This disease caused many deaths among the ancient Incas and among the followers of Pizarro during the conquest of Peru. Since 1730 various writers had described the disease. Carrion was a Peruvian medical student; he inoculated himself on each arm with blood from a tumor of a case of verruga, death occurring 39 days after inoculation, after he had passed through all the stages of oroya fever. Infected districts were limited to certain deep valleys of high altitude on the Western slope of the Andes. An organism, apparently a bacillus, was found in the red blood cells during the febrile period, and in the tissues of the local lesions. At autopsy enlargement of the liver, spleen, lymph nodes, and Peyer's patches was found. Anemia was very great, the red cells being reduced to 1,000,000 or 500,000; the polynuclear leucocytes were increased. Verruga, from which the disease took its name, was the most noticeable symptom. Two forms were recognized, the miliary and nodular. On section, verruga somewhat resembled sarcoma, had a stroma resembling embryonic tissue and a circumscribed adherent wall. The blood vessels were large and sinus-like. The prognosis was serious, according to some authorities the mortality was as high as 90 per cent. Some cases ended fatally in 20 to 30 days, while others ran a more chronic course. The therapeutic resources were limited and consisted principally of symptomatic and supportive treatment. Verruga had not been widely investigated as yet and it was believed that a further study of this interesting disease would prove it to be insect-borne and would perhaps throw some light on other diseases whose etiology and transmission were not yet understood.

The Simultaneous and Cyclical Appearance of Epidemics of Pneumonia, Grippe and Enteritis on the Northern Hemisphere and Their Synchronism with Cycles of Solar Activity.—Dr. C. M. Richter of San Francisco said that epidemics of acute diseases of the respiratory organs had as a rule appeared simultaneously during the last 25 to 40 years in different cities and countries on the northern hemisphere (Berlin, Italy, Chicago, Philadelphia, Cincinnati, Milwaukee, New Orleans, San Francisco, Victoria, B. C.) They recurred in cycles of about three to four, eight and eleven to twelve years, similar to the cycles of solar activity and polar lights. Likewise epidemics of acute diseases of the intestines occurred in certain cycles of a very similar but generally longer period (Berlin, New York, Chicago, San Francisco). The general prevalence of the first of the two groups of diseases depended on the presence of anticyclonic weather, while the latter depended on its absence. An ultraviolet solar radiation showed a synchronism inverse to the solar periods and as anticyclonic weather was the distributor of the upper air, which was ever modified by such solar activities, it appeared to be a logical conclusion that a further study and analysis of the air during anticyclonic weather and at different parts of our hemisphere should prove to be a fruitful research. Numerous charts were on exhibition at the "Scientific Exhibit" to support these views.

Successful Treatment of a Typhoid Bacillus-Carrier by Vaccination.—Drs. Walter Brem and F. C. Watson of Cristobal, Canal Zone, reported the case of an American girl, four and a half years old, who had typhoid fever in Colon Hospital in August, 1910. She was given three grains of hexamethylenamin three times daily for two weeks during convalescence. Shortly afterward her father and mother developed typhoid fever. On December 7 and afterward, numerous typhoid bacilli were found in the child's urine; the stools were negative. She was vaccinated nine times with autogenous vaccines between December 10, 1910, and February 1, 1911. The doses were gradually increased from 25 to 1,500 million. As vaccination proceeded, the number of bacilli gradually decreased until on February 15 the cultures were negative. The agglutination of the patient's serum reached one to one thousand against the typhoid stock culture and her own organism. The time during which typhoid bacilli were present was about six months. The phenomena suggested a chronic lesion slowly healing under the influence of vaccination.

Dr. Frank Billings of Chicago reported the case of a woman, 44 years old, who positively denied ever having had typhoid fever or anything that could be considered as typhoid fever. Yet she gave a positive Widal reaction and the feces gave a pure culture. She suffered from a chronic cholecystitis, was operated on and in the gall bladder were found calculi and living typhoid bacilli. One should be on the alert to discover these cases. A lesson should be learned: patients should not be turned out of the hospitals because they suffered from no symptoms without a very careful examination of the stools and urine. Many of these patients were a menace to the community. He treated his typhoid fever cases with enormous doses of urotropin, giving 120 grains a day. It certainly did have some effect upon the bacilluria. One could not depend upon the effect of this agent on the intestinal canal. Vaccination seemed to him to be a most valuable measure.

Major Percy M. Ashburn, U. S. A., reported an interesting case of a sergeant of the Fifth Field Artillery who was admitted to the hospital in San Francisco in November, 1909. He had had typhoid fever in October at Vancouver barracks. His stools were examined weekly during his stay, and always they found an abundance of typhoid

bacilli in the stools and practically in pure culture. In June, 1910, he was treated with autogenous vaccines and exposures to the *x*-ray, but without effect. This treatment was stopped then and the patient was given sodium salicylate every four hours. After taking this for two weeks his stomach became much disturbed and he complained of palpitation. But the number of bacilli in the stools had markedly diminished. The salicylate was stopped, but the diminution in the number of bacilli continued and about the last of May the stools were entirely free from them. He also reported another case of a typhoid carrier who was sent home from the Philippines and who, after eight months, was returned to duty.

Dr. William Litterer of Nashville, Tenn., reported a case in which the pus from a wound contained so many bacilli that to count them was almost impossible. After the first injection there were about 1,000 bacilli; after the second injection the number was reduced about one-half. The patient was finally cured. In another case he reported there was a pure culture of the typhoid bacilli. He had now under observation three typhoid fever carriers of the intestinal type and treatment so far had been unsuccessful. He had not been able to decrease the number of bacilli in the stools.

Causation and Treatment of Fever in Tuberculosis.—Dr. F. M. Pottenger, Monrovia, Cal., held that the former belief that pure tuberculosis fever did not exceed 100 or 101 degrees F., and that all high fevers were due to mixed infection, was probably erroneous. The actual causes were the toxins of the tubercle bacillus and other bacteria, as well as the toxins produced by the destruction of the body cells as a result of autolysis. Physical exertion, mental perturbation, complication, themometric and barometric changes were modifying factors. The treatment must be based on an accurate diagnosis.

Dr. Edward F. Wells, of Chicago, said that many years ago he had occasion to observe closely several cases of early tuberculosis in which this point was clearly brought out; the temperature curve continued for about one week, then became quiescent for two, three, or four weeks, and then began to rise again gradually. His observations were published several years ago and had particular reference to diagnosis. One point he wished to bring out as supplementary to his former observations was this: If tuberculin should be given for diagnostic purposes at the beginning of one of the febrile curves, the reaction following might be of value both in diagnosis and in prognosis.

Streptothricosis (Actinomycosis) of the Lungs.—Dr. Norman Bridge of Los Angeles read this paper and briefly summarized as follows: (1) The fungus was found to be markedly pleomorphic, occurring in (a) the classical grain or tuft, in culture, and in tissue: (b) fragmentations, bacillary, or even smaller, like granules, in tissues and discharges and some cultures (solid media), and very variable in size of mycelium. (2) The very young mycelium was resistant to all stains, the old threads likewise failed to stain. (3) In cultures and tufts the mycelium masses always showed large numbers of small Gram-positive organisms (spores). Fine branching mycelia in the very early stages started from these structures, demonstrated in hanging drop and smears. They were negative to Moeller's method for staining spores of ordinary fission fungi. They were not demonstrated in the tissues. (4) The active infectious agent in tissues was apparently the rod-segment. Cultures in bouillon always gave positive results, in the absence of fungus in the sputum visible to the naked eye. By the two methods, moreover, the Gram stain and the bouillon culture, a case that had been under observation for diagnosis was suspected and proved to be positive to culture. In a few days, with severe coughing and profuse expectoration, the microscopical granules appeared, clinching the diagnosis. If continued observations showed these two methods to be absolutely trustworthy, it would be possible to make an early and reliable diagnosis for this disease. The simplicity of the bouillon culture and hanging drop examination, together with some Gram-stained films, brought it within the reach of all who were near any sort of laboratory facilities.

Hemorrhagic Erosions of the Stomach, with a Report of the Autopsy Findings in a Case of Einhorn's Disease.—Dr. N. W. Jones of Portland, Ore., stated that of 600 consecutive cases the fasting stomach was examined as part of the general diagnosis, and this gave 35 cases with definite erosions (5.6 per cent.), including cases of pernicious anemia, general asthenia, carcinoma of the stomach, carcinoma of the esophagus, cardiospasm, dyspepsia nervosa, Schmidt's fermentation dyspepsia, Einhorn's disease, chronic gastritis, anacidity, subacidity and hyperacidity, chronic gastrosuccorrhea, chronic gall-bladder disease, chronic intestinal catarrh, spactic obstipation, chronic salpingitis, chronic ulcer of the stomach, etc. The cases grouped themselves into: (*a*) those without clinical symptoms, and (*b*) those with distinct clinical symptoms. (*a*) Thirteen of the 34 cases were found in chronic gastritis. The inflammatory change, the retching and stomach contraction, together with trauma of the tube, constituted etiological factors. Two of the cases were associated with malignancy. The remaining 19 cases were seemingly produced by retching and trauma of the tube alone. The study of the fragments microscopically gave no further light on the etiology. (*b*) There were two types of hemorrhagic erosions with distinct clinical significance: (1)the simple erosion of Dieulafoy; this was not discussed except to emphasize the importance of its recognition and of employing radical medical means and not of resorting to surgical measures. (2) Einhorn's disease, in which there was an absence of all post-mortem evidence of underlying pathology. He reported a case that came to autopsy which threw light on this disease. A brief résumé of the pathology was as follows: There was the picture of a form of chronic gastritis characterized (*a*) by a dense, small round-cell infiltration in the interstices of the glandular elements which when extensive obliterated the gastric glands by pressure; (b) by the disintegration of the cuticular portion of the mucosa, as the crypts were displaced by the same round cells; and (*c*) by the fact that with the disintegration of the cuticle and crypts the congested vessels were exposed and ruptured, which accounted for the gastric hemorrhages occurring in the clinical course of the disease. The absence of proliferation of connective tissue elements, the engorgement of the superficial blood capillaries, and the manner in which the gland cells were destroyed sharply differentiated the process from chronic gastritis. It was neither ordinary chronic gastritis with the element of erosion formation added to it, as had been claimed, nor a distinct disease entity, as claimed by others, but a chronic non-proliferative hemorrhagic gastritis, and presented probably a uniform pathological picture.

Dr. Robert T. Morris of New York said that these cases of hemorrhagic erosion were not cases for the surgeon. Surgery did not at all comprehend the question and failed to give relief because the original condition was not removed by operation. Again there were the shock and other features which were incidental to the operation which were not desirable. There was one point, however, that Dr. Jones had not brought out, and this was a very important one. The patients should have treatment when the erosions occurred. They should keep trace of the toxic history in these cases. They should remember that hyperchlorhydria and hypochlorhydria were symptoms like coughing or sneezing, that was all. The hormones had sent the wrong message to the secreting glands. What

reason had they for believing that the toxins excreted were basic factors in the causation of these erosions? What was met with in the abdomen might give them a clue. They often found peritoneal adhesions so general that they must assign some significance to them. They often met with cases of adhesions, "cobwebs in the attic of the abdomen," due to the excretion of toxins by the liver; bacteria chiefly of the colon bacillus group passed the liver unharmed, but they set up trouble in the bile-tract. The endothelium desquamated, lymph was excreted, coagulation occurred, and then adhesions were formed. All this resulted not only in erosions and hemorrhages from the stomach and pylorus, but the toxins influenced the spasm of the terminal arteries of this region.

Dr. J. F. Hultgen of Chicago said that the question of the erosion of the stomach had not been considered enough in connection with the constant anemia found in all these cases. He thought that possibly the symptom complex might be due to the anemia itself. As a matter of fact the anatomical basis, so far as was shown by Dr. Jones, was not sufficient to explain the clinical course of the disease. He believed that gastric hemorrhage from the erosion was nothing but a symptom and not the underlying disease, which might be of hemolytic nature, toxic or of unknown origin.

Dr. Philips King Brown of San Francisco said that so long as there was associated with the hemorrhage pain, it might be the result of chronic disease of the appendix which had been described so fully and best by Moynihan several years ago. He reported 12 cases, the symptoms of which were the classical ones of gastric ulcer; at operation no ulcer was found. In each case, however, there was a diseased appendix. The removal of the appendix caused all the symptoms of gastric ulcer to disappear.

Immuno-Diagnostics in Internal Medicine.—Dr. W J. Butler of Chicago considered the theories of immunity, especially in its relation to the development of immuno-diagnostics. He called attention to the necessity for conservatism in making deductions from positive and negative results in all immunity tests.

The Leucocytology of Typhoidal Diseases as a Group Phenomenon Within the Typhoid-Colon Family of Bacilli.—Dr. J. F. Hultgen of Chicago read this paper and concluded as follows: (1) There existed a typical typhoid and paratyphoid blood picture throughout the course of these diseases: (2) This blood picture was characteristic of the obligate parasites of the typhoid-colon group and constituted probably the counterpart to that usually found in colon bacillus infection. (3) The leucocyte reactions of typhoid and paratyphoid infections must be interpreted as group phenomena. (4) In the pathogenesis of this typhoid-paratyphoid blood picture the germs and lymphatic tissues played a joint rôle, but the character of the intoxication determined the blood picture. (5) The diagnostic value of the leucocyte picture was particularly great during the first 10 days, while its prognostic value was especially marked in the last 10 or 15 days of the disease. (6) Repeated combined total and differential counts must be made throughout the course of typhoid or paratyphoid fevers. The cytology of these affections could be appreciated in no other way. (7) The immunity with leucopenia of the typhoid-paratyphoid group and the immunity with active leucopoiesis of the colon wing of this family were evidently the two extreme phases of one fundamental process. (8) The above blood charts and reasoning by analogy showed that the conception of the typhoid blood picture as a group phenomenon within the typhoid-colon family was correct. (9) Each member of the typhoid-colon bacillus group was able to produce either a toxic gastroenteritis or a true typhoid affection. (10) The close, or fundamental, kinship between the numerous members of the typhoid colon group of bacilli was proven, first, clinically by the time-honored name of typhoid fevers; secondly, pathologically by their common faculty of producing ulcers in the gastrointestinal tract; thirdly, cytologically by their blood picture; fourthly, serologically by the coagglutination of Pfaundler; fifthly, epidemiologically by Hazen's theorem of the Mills-Reinke phenomenon of typhoid and general mortality. (11) The law of periodicity of inorganic chemical elements as announced by D. I. Mendeléeff in 1869 was, in his opinion, applicable to the district group arrangement of organic living micro-organisms.

SECTION ON DISEASES OF CHILDREN.

Tuesday, June 27—First Day.

Dr. S. M. Hamill of Philadelphia in the Chair.

The Opportunities of the Pediatrists in the Prevention of Death and Disease in Early Life.—Dr. S. M. Hamill of Philadelphia went thoroughly into the question of public health in the large cities and the congested districts. Compliment was paid to the work being done to remedy the existing conditions and suggestions were made for the co-operation of pediatrists with those now actively engaged in this work. As customary with the chairman's address, there was no discussion.

A Study of Children in Reference to Enteroptosis.—Dr. Richard R. Smith of Grand Rapids read this paper, which was profusely and effectively illustrated with lantern slides and *x*-ray pictures. He called particular attention to trunk development and the fact that the prolapse of organs was seldom (if ever) found until after the tenth year. In a series of 50 children examined, prolapsed kidney was not found, showing that this was not a congenial condition. Examination of a number of infants showed a condition of prolapsed kidney which afterward disappeared. He called attention to the fact that an elongated stomach was not necessarily a pathological condition, and that it would take care of food. He said that the "ideal stomach" was found only in the vigorous adult, but it was common in children. Healthy infants had the "cow horn" stomach well up under the diaphragm and even very fragile children usually had a normal stomach. In conclusion he said that every pathological tendency of adult life was found in the delicate child, although actual prolapse was rarely found. Prolapse of the stomach, kidneys, colon, etc., not commonly present in children, was compared with the frequency with which it occurred in adult life.

Dr. Butler of Chicago said that the acquired type of enteroptosis was never seen in children, but the congenial type was so common as to raise the question as to its being an abnormality. He thought that what would be termed an enteroptosis was a regular occurrence in infants, and that the body forms of children began to show in what was called the "second stretching period." He emphasized the lack of atonic conditions, and organic displacements, however, except in unusual circumstances, before the twelfth year. In his examinations he had not found a stomach below the umbilicus (under gas distension) before the twelfth year. He expressed the belief that the ill-health of many women had its origin in this enteroptotic habit of childhood. He said that organic displacement might be carried for years without symptoms, but that many symptoms showed a severity entirely out of proportion to the displacement to be found. He suggested as the best preventive measures that these patients, especially the neurotic, should be kept in as high a state of nutrition as possible.

Dr. I. A. Abt of Chicago said that he had had a case, that of an infant, with marked floating kidney descending away down into the pelvis; that he had from time to time examined this patient and that now, in her twentieth year, he could not feel the kidney at all, showing that it might be possible for these cases to recover spontaneously. He also called attention to the possibility of falling into error

in estimating the size of the child's stomach, feeling that one had symptoms of pyloric stenosis when it was only a normal stomach.

The Institutional Care of Young Infants.—Dr. Thomas S. Southworth of New York showed that institutions for this purpose had not the advantage of the asepsis expected, as shown by years of trial. He said that the factors contributing to the large mortality were delay in transmission to institution, disturbance of vital functions and digestion, questionable initial care in institutions, too few wet nurses for premature and delicate children, and routine feeding rather than adapting each child's food to its needs. He said that the large wards were greatly responsible for the spread of infectious diseases and that the necessity for large air space was not appreciated. He said that the lowest mortality obtained where mother's milk was used and individual care was given. He said that one must not condemn the institution until these remedies had been applied to the routine now being used. He showed that exposure, fatigue, and the probable disturbance of digestion acquired before the infant came to the institution, prevented good results. He presented complete details for the fitting up of receiving stations, and the construction of apparatus for maintaining body heat, and described the treatment to be given the infant as soon as it was received. He also explained how wet nurses might be obtained, and the necessity for a good milk laboratory for the preparation of proper milk for each individual child. He said that common illness looked upon lightly in the home became a serious affair in a crowded ward where the air was overheated and not fresh. Instruction should be given nurses as to the possibility of infection, through the agency of their hands and clothes, of bronchial troubles in winter and digestive disorders in summer, both of which groups of diseases were not commonly supposed to be infectious. In conclusion he said that when institutions accepted the best of both institution and boarding-out methods, the best results would be obtained.

Dr. G. Eliot of Connecticut said that the best results were obtained where institutions were located in the country, where the buildings could be of one story, cheaply constructed and torn down every three to five years and replaced. When they were located in the country the milk could be fed to the infants direct from the cows instead of being 24 or 36 hours old or older.

Dr. James W. Cokenower of Iowa said that in his work in the Iowa Children's Home during the past fifteen years he had handled about 7,000 babies. He said that the first great difficulty arose from the incomplete history when admitted; and the second, from infection brought in with the newcomers. He said that it was rare to have a disease break out in institutions after children had been under its management. He called attention to the necessity of looking after excretions and secretions. He said that their institution owned its own cows and regulated each infant's food most carefully to suit its needs. He said that frequently children were brought to them with the stomach muscles so relaxed that they could feed neither by mouth nor enema. In these cases quinine and olive oil inunctions were used when the surface would permit of them. If not, a flannel cloth was saturated with the strength which would be tolerated, and after this had been used the child was completely wrapped in cotton and silk and thus given the complete rest which the stomach needed, and to this method he attributed the recovery of many children.

Dr. Langley Porter of California thought that in twenty years no one would be found advocating the retention of an institution. He said that the San Francisco Children's Home and Aid Society had done away with it entirely. He said that the real problem lay in educating the public. He thought that the economic side deserved consideration; that where money was not tied up in equipment and outfitting it could be used for the procuring of a better class of nurses for children.

Dr. I. A. Abt of Illinois took issue with Dr. Porter on the question of the abolishment of institutions. He thought that while institutions were not all that they might be, the ill results could be lessened and there were many good features. He said that an infant asylum or hospital depended for its results upon the energy, soul, and brains put into it; that if technique, asepsis, and good food were insisted upon and good nurses secured results were bound to be in proportion. He said that from experience with both he had come to the conclusion that the hospital was a necessity, but he said that one might as well try to run a hospital without an operating room as an institution without wet nurses. He said that both physicians and nurses were entirely too careless about communicating disease, and made a strong plea for individual utensils for each infant. He also stated that the matter of starvation had gone too far and that babies were often physicked to death. He said that after the intestines were thoroughly cleansed further cathartic brought about a pathological condition of the mucous cells.

Dr. W. W. Butterworth of New Orleans said that in the South institutions would never be abolished because the only possibility of boarding out was in the homes of the colored. He said that while the mortality rate was so high there was something radically wrong and he laid it partially to the fact that the institutions were usually sectarian. He said that each institution should be under the supervision of a board of medical men. He said that a practical solution of the question of isolation of infectious diseases lay in the glass partitions now used in Paris, which could be put up at will and adjusted to the various needs.

Dr. McCleve of Berkeley, Cal., said that in the San Francisco Hospital, under the boarding-out system the mortality was lowered from 40 to 20 per cent; after the supplying of certified milk it dropped to 2 per cent, where it now stood.

Dr. W. V. C. Francis of California said that one of the difficulties in institutions in the Southwest was keeping out ants and flies. In their institution they had established the routine habit of giving one dose of castor oil to each child and nothing more unless definitely ordered by the physician.

Dr. Thomas S. Southworth, in closing, said that in the East he did not think it would ever be possible or practical to abolish institutions, but he said that any institution was successful in just so far as the nurses could be depended upon; that suitable milk must be insisted upon and infection eliminated by a quarantine of two weeks and that visitors to the child should be cautioned.

The Baby Tents.—Dr. Frank W. Allin of Chicago, Ill., read this paper by invitation. He called attention to the inadequacy of all methods in use in Chicago to lower mortality; that in one year there were 6,888 deaths among children under one year. One of the great difficulties lay in the fact that congested districts where need of fresh air was so great were removed from the sanatoria on the lake shore. He called attention to the fact that organized effort to save the babies was a recent measure. Statistics showed that the percentage of deaths was far greater in crowded districts, so that fresh air was just as much a consideration as good milk. To meet this the baby tents were instituted seven years ago. They were placed on roofs or in vacant spaces, fitted with a hospital tent, receiving tent, and milk tent where milk in any modification was supplied to mothers at cost. Eight iron beds were placed in the tent, also electric lights, two electric fans, and a telephone. The tents were opened July 10 and remained open until September 15. They were kept open nights and on Sundays only during excessive heat or in emergency. Trained

nurses and interns were in attendance and visiting nurses were employed in the neighborhood. Doctors (chiefly from the Pediatric Society), were assigned for two days each week and assumed control of all the cases of that day, prescribing for others only in emergency. No patients of more than two years of age were admitted. When the patients failed to return, the visiting nurse was sent to investigate. He said that all mothers could not be induced to leave their babies in tents, but much good was done by close association of mother and doctor, and that when the baby did not do well the mother could be induced to leave it. The first year sixty were cared for, and last year with eleven tents in operation 1,750 were given close personal attention. The mortality last year (and all cases which died at home within three days after being in tents were included), was 1.75 per cent. The most successful tent received 363 patients; these were seen on an average of four times each; the number in a tent daily was 12; the deaths were 2. The total death rate for the season was .55 per cent. Many large cities have adopted the tent plan. Organizations were largely financing the undertaking, but the cost last year was $5,000.

Dr. J. P. Sedgwick of Minneapolis said that in their tents they had a perforated iron pipe connected with the city water supply along the ridge of the tent pole. In the case of excessive heat the water was turned on and allowed to saturate the canvas, and by evaporation it greatly lowered the temperature. He said that since the establishment of the tents the death rate as compared to the hospital records of the same period five years before was exactly cut in two.

Dr. May Michael of Illinois said that a valuable addition to one Chicago institution was a wet nurse.

Dr. F. Allin in closing said that in Chicago during extreme heat they had frequently placed a large block of ice in a tub before the electric fans, which lowered the temperature.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

Tuesday, June 27—First Day.

Dr. H. G. Wetherill of Denver in the Chair.

Carcinoma of the Clitoris and Report of Case.—Dr. Charles D. Lockwood of Pasadena, Cal., read this paper, in which he commented upon the comparative infrequency of tumors of the clitoris, and particularly of malignant tumors. He reported a case in which intense pain on urination was the most prominent symptom. Examination showed a characteristic, granular ulceration in the region of the clitoris. He completely excised the mass, which proved to be an epithelioma. It recurred in the inguinal glands after eight months, those of the right side being more prominently involved. Death occurred two years after the first operation. Irritation by means of discharges, syphilis, psoriasis, or chronic eczema seemed to be the prominent etiological factor in these cases. The glands were involved late. Recurrence was very frequent. The author had found reported 157 cases of tumor of the clitoris, of which 70 were epitheliomata.

Torsion of a Subserous Pedunculated Fibroid Complicating Pregnancy at Four and a Half Months: Operation, Recovery, with Delivery at Term.—Dr. E. M. Lazard of Los Angeles presented this paper, in which he said that while it was formerly believed that fibroids complicating pregnancy were a rare condition, a study of the literature showed a large number of reported cases, very few of which required operative interference. The condition was of interest on account of the accidents of pregnancy and association with malpositions, placenta previa, and retained placenta. Many cases went unrecognized. Gangrene of the tumor generally attracted attention to the condition, being caused by direct pressure or torsion of the pedicle. There were three cases of pedunculated fibroid reported in the literature. The author reported a case of a primipara who at four and a half months had a sudden sharp pain in the right side, followed by a fainting spell. A mass was discovered on the right side, which on operation proved to be a pedunculated fibroid with a gangrenous pedicle. The mass was ligated and removed, the patient's recovery being uneventful, and delivery being effected at full term by forceps. The puerperal period was uneventful, excepting for a high pulse due to hyperthyroidism.

Dr. J. S. Baer of Camden, N. J., said that he had never observed a case of this kind. He remembered five fibroids of the uterus complicating pregnancy at term, requiring forceps delivery or cesarean section. These cases bled more after delivery than a normal case.

Adiposity of the Mammary Glands.—Dr. J. R. Guthrie of Dubuque, Iowa, and Dr. Henry Albert of Iowa City presented this paper. They said that cases of a true adiposity of the mammary gland were comparatively rare, most of the cases of macromastia being a simple hypertrophy of connective tissue or glandular elements. In 69 reported cases, three had excess of fatty elements. In his case excessive adiposity was increased during pregnancy. Enlargement was associated with pain and tenderness. Toxemia required an abortion at seven months. Total amputation of both breasts was performed on account of the size and persistent tenderness, recovery being uncomplicated except for mild infection of the right wound. Microscopically the glands were found to be composed almost exclusively of adipose tissue.

The Exciting Causes, Means of Prevention and Early Treatment of Cancer of the Uterus.—Dr. A. E. Benjamin of Minneapolis read this paper. He commented on the lack of co-operation between the public and the physicians in the treatment of cancer. The death rate from cancer was rapidly rising, more women now dying from cancer than from tuberculosis. The exciting cause was usually local trauma associated with poor hygienic conditions. Every case was said to be founded on a chronic cervicitis. Every laceration of the perineum or cervix should be repaired at once. The necessity of bringing before the public the cause, and the importance of leucorrhea metrorrhagia, and menorrhagia, and the fact that 80 per cent of cancers were preventable and curable, was impressed upon the minds of those present. He urged complete hysterectomy in early cases, and cautioned against the radical operation in late cases on account of the unfavorable influence it might have upon the laity. He urged the necessity of exciting interest in the subject and of careful observance and recording of symptoms.

Dr. J. S. Baer of Camden, N. J., agreed with everything that Dr. Benjamin said. He had always urged the necessity of investigating any discharge at the menopause and advised examination of a section of the cervix in suspicious cases.

Dr. A. E. Hertzler of Kansas City said that nearly all of the cases sent to the surgeon had been bleeding for months or years, and were not operable. When the cases were easily diagnosed clinically they were not curable.

Dr. J. O. Polak of Brooklyn, N. Y., said that the New York Gynecological Society had recently gotten up a leaflet headed "What every woman should know in order to prevent death from cancer of the womb." Acetone was of value, but operation even in the presence of incurable cases prevented loss of blood and reduced toxemia.

Dr. Laura H. Branson of Iowa City, Iowa, said this subject was of great interest to her, particularly the subject of the prevention of cancer. She believed in the immediate repair of the cervix.

Dr. C. D. Lockwood of Pasadena did not believe that it was good policy to advise immediate repair of the cervix

except under the most favorable conditions, on account of the danger of sepsis and the possibility of leaving a large amount of scar tissue in the cervix.

Dr. T. Mitchell Burns of Denver did not believe in immediate repair except in certain operative cases. He believed that from six weeks to two months after delivery was the proper time to do the repair.

Dr. J. T. Reddick of Paducah, Ky., said that on account of edema of the cervix he believed it advisable to wait some time before repairing the cervix.

Dr. Baer of Camden, N. J., said that he did the immediate repair only when surrounded by the most favorable conditions.

Dr. Titan J. Coffee of Los Angeles examined his cases eight or nine days after delivery and did the repair if necessary. He used a 10 per cent. solution of cocaine as the anesthetic.

Dr. H. P. Newman of San Diego urged the necessity of early operation in all of these suspected carcinomata.

Dr. Burke of Redlands said that he believed Dr. Coffee's suggestion was a good one. He believed the physician was at fault who did not recognize operable cases of cancer.

Dr. W. B. Dorsett of St. Louis never repaired the cervix except for hemorrhage. His cancer cases had nearly all lived in a swampy district. He emphasized the importance of curettage and the actual cautery for inoperable cases.

Dr. Benjamin closed by stating that he believed in immediate repair under right conditions, and was much gratified by the discussion of the paper.

Relation of Exophthalmic Goiter to Pelvic Disease.—Dr. Arthur E. Hertzler of Kansas City, Mo., reported a series of cases in which there was in each case pelvic disease which antedated the exophthalmic goiter. In his first group, correction of pelvic trouble by operation cured four of five cases and improved the fifth. In the second group there was pelvic disease, but operation was not performed. In many cases the pelvic conditions were found only on examination, no history being given. Concluding, he said that perhaps one was not so sure of the pathogenesis of goiter as one was prone to believe. The relation of the thyroid to the pelvic organs was well marked.

Dr. Lazard of Los Angeles said that in his case of pedunculated fibroid there was no history of previous pelvic disease, and after operation and delivery the symptoms of hyperthyroidism persisted.

SECTION ON SURGERY.

Tuesday, June 27—First Day.

Dr. George W. Crile of Cleveland, Ohio, in the Chair.

To fill the vacancy in the Executive Committee caused by the death of Dr. J. C. Munro of Boston, the Chairman appointed Dr. Charles H. Frazier of Philadelphia.

Newer Methods for Further Increasing the Safety of Surgical Operations.—Dr. G. W. Crile of Cleveland divided operations into two classes: (1) Those on patients in fair health, such as operations on the uterus and ovaries, simple gall-bladder and hernia operations, operations for cancer of the breast, simple goiter, etc.: and (2) those on patients whose vitality had been lowered by accident, infection, or prolonged illness, such as severe crushes, peritonitis, starvation from pyloric obstruction, etc. Of 10,723 personal operations 4,127 were in the first group, with a mortality of 1 in 325 cases. All cases had temporary nervous impairment, such impairment varying with the individual, working women as a rule having less than women living in luxury. For this nervous impairment there was a physical basis. The central nervous system was damaged; brains after fatigue, injury, drugs, shock, etc., having been examined and anatomical changes having been observed. Severe infections, shock, and emotions even were the cause of surgical deaths and showed changes in the central nervous system. Three factors increased the damage to the central nervous system: (1) fear, (2) trauma to tissues, and (3) anesthesia. Fear was stronger than the will and required drugs for control. Morphine and scopolamine allayed fear and gave a neutral state. Owing to the abolition of the association fibers one should prevent the effects of trauma to the tissues by using a local anesthetic to block all impulses from the site of operation to the brain. Under the use of nitrous oxide anesthesia the effect of trauma on the brain was only one-fourth as much as when ether was used. Crile had had personal experience with 2400 operations under nitrous oxide and Dr. Teter had given it 17,762 times without a fatality. After the nerve cells of the brain had been damaged and vitality had been lost restoration could be brought about by direct transfusion of human lood. In industrial accidents and grave diseases where vitality was low, the remaining vitality should be conserved by the use of nitrous oxide as a general anesthetic and cocaine as a local anesthetic, to prevent impulses reaching the brain, and also the restoration of the exhausted nerve cells by direct transfusion. In 2410 cases so operated on there was a mortality of less than two per cent. Slides were shown illustrating the appearance of brain cells in the normal condition, in toxemia, in fatigue, in fright, etc.

Brachial Palsy.—Dr. Charles H. Frazier of Philadelphia read a paper on supraclavicular, subcutaneous injuries to the brachial plexus without skeletal injury. From 1873 to the present time there were 21 cases on record. The case reported was that of a physician who was struck on the shoulder by a man who fell four stories. Examination showed a lesion of the 6th, 7th, and 8th cervical nerves. On account of severe pain it was proposed to cut the posterior roots of the 5th, 6th, 7th, and 8th cervical, and the first dorsal nerves. Laminectomy was done; the 6th, 7th and 8th roots were found already divided. In diagnosis hysteria and hematomyelia must be considered. An operation in continuity might appear complete, yet with loss of function owing to division of the axis cylinder processes. The prognosis without operation was bad and with operation was not very good, but improvement might take place. One should not postpone operation. There were four classes of cases: (1) loss of function without rupture: (2) rupture in an accessible place; in these cases ends should be freshened and sutured; (3) rupture in an inaccessible place; and (4) neuralgia. In the last two cases the posterior nerve roots should be resected. Another observer had had six cases in the past two years without a fatality.

Dr. W. W. Grant of Denver spoke of the importance of preventing the formation of excessive scar tissue at the site of suture of a nerve. Personally he used cargile membrane.

Advantages of the So-Called Decortication of the Lung for Old Empyemata.—Dr. Fred B. Lund of Boston read a paper stating that in old empyemata there was a cavity with rigid walls and either the chest wall must be collapsed or the lung made to expand. The first method was a very severe operation and very deforming, especially in growing children causing lateral curvature. In 1893 Delorme, in France, and Fowler, in America, practised removing the plastic exudate from the lung, allowing it to expand. This was safer and less deforming than resection of ribs. Lund had seven cases. He made his incision upward and forward from the original incision, opened the pleural cavity and dissected the thickened pleura from the lung. The air cells of the lung were but rarely injured, as evidenced by the escape of air. The

expansion of the lung was immediate and recovery was prompt.

A Plea for More Direct Methods in Dealing with Gastric Ulcers.—Dr. Robert C. Coffey of Portland, Oregon, stated that gastric ulcer was not always cured by gastroenterostomy and advocated excision of the ulcer. He had a death from hemorrhage due to injury to an artery by the clamp. Therefore he perfected a technique of excision without the use of the clamp. The clamp served three purposes: (1) to hold the viscus, (2) to prevent extravasation of gastric contents, and (3) to prevent hemorrhage. He accomplished the same purpose by traction sutures to steady the viscus and by the traction elevated the walls of the stomach so that air entered the elevation. The incision was then made and the gastric contents were removed with a ladle and sponges and the entire mucosa was inspected. If the ulcer involved the posterior wall the lesser peritoneal cavity was packed with gauze, the ulcer was excised and the wound sutured. Hemorrhage was prevented by making an incision parallel to the blood-vessels. Thus all the advantages of the clamp were obtained without danger of injury by that instrument.

Dr. J. W. Draper Maury of Rochester, Minnesota, described a method of excision of a portion of the stomach by means of a pentagonal stitch of twine which cut its way out and did not necessitate opening the stomach.

Dr. Skinner of Geneva, N. Y., mentioned a paper he had read three years ago in Atlantic City describing an operation on the posterior wall of the stomach through an incision in the anterior wall. He stated he did not use clamps in stomach operations, but washed the stomach out by a nasal tube and allowed the tube to remain *in situ* during the operation.

Dr. Andrews of Chicago stated that the pendulum was swinging from the indirect method of treating gastric ulcers back to the direct method. The direct methods had disadvantages.

Dr. C. H. Mayo of Rochester, Minn., stated that he used clamps and had no ill effects from them, but had bad hemorrhages from the ulcer and also from the suture line. He stated that one-half of the cases of gastric carcinoma had been preceded by a history of ulcer, therefore a callous gastric ulcer were better excised. Ulcers of the duodenum were not prone to carcinoma.

Dr. A. J. O'Connor of Chicago stated that he had no fear of hemorrhage from the use of the clamps. The pentagonal stitch might be of service if the ulcer were small, but in those cases it was not necessary. On the other hand it caused too much puckering if the ulcer were large. One should approach the posterior wall of the stomach through the transverse mesocolon.

ELECTION OF OFFICERS.

The following officers were elected by the House of Delegates of the American Medical Association:

President.—Abraham Jacobi, M. D., New York.

First Vice-President.—W. Jarvis Barlow, M.D., California.

Second Vice-President.—Floyd W. McRea, M.D., Georgia.

Third Vice-President.—William R. Tipton, M.D., New Mexico.

Fourth Vice-President.—William T. Wright, M.D., Iowa.

Secretary.—Alexander R. Craig, M.D., Pennsylvania.

Treasurer.—Wm. Allen Pusey, M.D., Illinois.

Trustees.—Philip Marvel, M.D., New Jersey.
Philip Mills Jones, M.D., California.
Frank W. Searles, M.D., Illinois.

Next annual meeting at Atlantic City, N. J.

AMERICAN ASSOCIATION OF MEDICAL EXAMINERS.

Eleventh Annual Meeting Held at Los Angeles, Cal., June 26 and 27, 1911.

(Special Report by Telegraph to the Medical Record.)

Monday, June 26—First Day.

The President, Dr. Liston H. Montgomery, of Chicago, in the Chair.

Address of Welcome.—Dr. Wesley Wilbur Beckett of Los Angeles, Medical Director of the Pacific Mutual Life Insurance Company, delivered this address.

Life Insurance Companies as a Factor in the Progress and Problems of a Great Nation.—Dr. Liston Homer Montgomery of Chicago said that the greatest accumulation of private funds and the greatest aggregation of money were those in certain life insurance companies. The funds paid into life insurance companies should not be owned by these companies. In the handling of money there should be a maximum of safety with a minimum of cost. He considered the question of industrial insurance. He advocated the formation of a national department of health, and law or laws should be enacted to obtain such a department. Every individual was a producer and the country should protect the life and the welfare of its people. That was patriotism. A patriot resulted from the love of an individual for his country and the government should love such a man. Public sentiment endorsed the formation of a national department of health. There should be a separate bureau for this department of health. Dr. Montgomery was very enthusiastic in this matter. It was a matter of regret that to-day not more time was allowed members of the medical profession to enter the field of politics. He proposed that they should have appointed five members to consider the advisability of formulating some plan to further this idea and to make suggestions toward the accomplishment of the formation of a national department of health, and to report back to the meeting the results of their deliberations before adjournment. Life insurance companies should be conducted as beneficent institutions and not as commercial money-making affairs for the accumulations of millions of dollars with their perversion of sacred trust funds. In closing, Dr. Montgomery said that the medical examiner should be cloaked with good horse sense and diplomacy. If a man was examined and said that his appendix was in a glass bottle, he was a safer risk than the man who had his appendix in his abdomen. Life insurance premiums were too high. A national department of health and the bureau of life insurance should be merged.

The Medical Examiner.—Dr. Allison Maxwell of Indianapolis, Ind., said that the life insurance companies depended upon their medical examiners to keep down their mortality rate and this was a very strong argument for the selection of examiners of integrity and ability. The qualifications required of a medical examiner were many; to be successful he should have tact, and the moral courage to protect the company even though in doing so it drove away patients and possibly friends. The medical examiner should be continuously on his guard to discover whether or not the risk was a good one. There was the moral hazard encountered: often the medical examiner saw in a man something which was difficult to estimate, but the medical examiner could write many things to the home office which would be of value, such as the fact that the applicant was leading a very immoral life, etc. Dr. Maxwell believed that the medical examiners for life insurance companies were, as a rule, honorable and the best educated men in the community. Of course, they did make mistakes at times.

Dr. L. L. Stevens of Seattle, Wash., thought that each of those present had been in the position of a medical examiner looking upon the applicant from the physician's standpoint. There were many perplexing questions that frequently arose; many had patients whom they had treated for years, who appeared before them for examination for life insurance. Many times examinations were made and, for instance, a mere trace of sugar found; if this was reported to the company the applicant no doubt would have been rejected, and after that rejection this individual would never be able to secure life insurance. They sometimes felt that occasionally they might be wrong. Therefore as physician and as a friend of the applicant the case was not reported and the report was postponed. This was looking at the matter from the standpoint of physician and friend of the applicant. One of the requirements for a good medical examiner was loyalty to the company. They knew that some cases of diabetes mellitus during the incipient period would recover; but such patients did not make good risks. Dr. Stevens thought that medical directors would bear him out in the statement that it was better to report cases as they found them. Let the medical director decide whether the applicant should be completely rejected, or should be allowed to take out some other form of policy. Another point which might at first appear to be a trivial one was the necessity for clearness in writing and correct spelling; this might save the home office many hours of work.

Dr. Allison Maxwell said that the medical directors should impress upon the medical examiners the desire of the former that the examiners be sincere always; the directors would try to treat the examiners in the same way.

Why Physicians Who Are Good Business Men Are in Demand by Insurance Companies as Examiners.—Dr. Charles Cutting of Seattle, Wash., presented this paper, which was read by Dr. L. L. Stevens. He stated that now as never before the members of the medical profession realized that to be successful the practice of medicine must rest upon business principles. A man could not give proper thought and study to his work if he was harassed by business difficulties. Of the thousand lines of work the doctors probably suffered more from financial embarrassment. Was it true to-day that medicine was in a chaotic state? It was true; medicine to-day was in a chaotic condition, because they as physicians had been blind to the business side of the work. They had neglected to study the patients; they could not get the patients' attention, and so these had left and gone over to the quack, the Christian Scientist, the mental healer, etc., from whom they got both mental and the physical assistance. There were too many *isms* and fads to-day. The physicians must have the sera, drugs, and surgery, but above all they should have common sense. They could not afford to be ignorant of human nature. The man that had a good business training made the most useful and successful physician. Many physicians made good claim adjusters. The art of making a good physical examination rested largely upon the sense of observation. The following were some of the reasons why the position of medical examiner was attractive: (1) The demand for accident, health, and liability insurance was steadily on the increase. Accident and health contracts were for short terms only, not exceeding one year. Every man the world over desired protection against loss of time from disability caused by either accident or sickness. This applied to men and women, employer and employees. (2) The short time required to make accident and liability examinations appealed to the busy practitioner and he could, in the majority of the cases, arrange the time and place to suit his convenience. Thus it was possible to make a number of such examinations in the time usually required to examine one life applicant. (3) The fees ranged all the way from $2 up to $10, and where the cases went to court the examiner was asked to report again upon the condition of the plaintiff before trial and to testify during the trial, for which fees were paid in accordance with the custom of the locality where the examiner lived, from $25 to $100 a day. (4) The insurance agent was a good fellow, but alas, many times a thorn in the flesh of the life insurance examiner. Not so, however, in the accident, health, and liability field. The agent was in no way connected with the doctor and was unable, therefore, to harass him. (5) The successful examiner must be a good diagnostician. Never in the history of medicine had correct diagnosis been so essential as it was to-day. He was also called upon to make a prognosis, the accuracy of which depended largely upon his experience in this line of work. Such training was invaluable. (6) If the examiner proved satisfactory to his accident or liability company, if his diagnosis and prognosis showed that he was a man of ability, it was not long before he was likely to find himself serving as an adjuster for the company. That the skilled examiner made the best adjuster was gradually being conceded by the up-to-date and progressive insurance companies. The physician proving his ability in this line assured himself of a permanent position and made himself indispensable to the company, and this in turn meant a good sized income and 100 per cent. of collections. (7) The high class accident and health policies were sold to selected business and professional men, whose acquaintance was worth cultivating, and many an examiner had become the family physician of the assured and had more than doubled the size of his practice in a very few years. On the other hand, the industrial accident policies were sold to the working people and the examiner soon found his practice increasing in this direction also. (8) To cultivate the power of observation was the aim of every progressive physician. To be able to prove that his diagnosis had been correct was particularly gratifying. Most disability policies had a clause whereby the company had a right to perform an autopsy in case of death and the examiner who had demonstrated his value to the company was likely to be called at any time to do a post-mortem which not only called for a good fee, but was the best possible kind of training for a physician or surgeon. (9) Physicians averaged to collect about 75 per cent. per annum from their practice. Examiners were paid regularly at the expiration of 30 to 90 days, and their collections were always 100 per cent. (10) Accident companies were requiring more examinations in cases of claims than ever before. The demand for a higher grade of work would continue to increase year by year. The examiner would gradually take the place of the attorney and claim agent in the adjustment of a large percentage of claims. The following were a few of the necessary qualifications for success: (1) A thorough technical training. (2) The examiner must have a good address and appearance, be well groomed and tactful at all times. (3) Every examiner must develop the power of observation. (4) Many companies required the examiner to give his idea as to prognosis and the probable period of total or partial disability. (5) He should be able to tell approximately the length of time the insured was likely to be disabled. (6) He should be able to state whether or not the insured was disabled by accident or illness. This played a very important part in the adjustment of claims. There should be a close study of the relation between injuries and illness. (7) He should be a good listener; he should let the insured do the talking, and the examination should be made in the shortest time possible. (8) In making a prognosis the examiner should take into consideration all the facts. (9) Having made the examination and having used every available means to ascertain all the facts, the examiner then must accurately present his report on paper and in a manner which would be understood by the home office.

Dr. G. Strohbach of Cincinnati said that the subject under discussion interested him very much, because his hobby was economics. He wished to encourage sane methods in conducting the practice of medicine. Medical economics should be taught in medical colleges. In the State of Kentucky the board of examiners, after a brief period, would refuse to examine a physician who had not had and passed a course in economics. He said that to-day almost everything that pertained to medicine was in a chaotic state. They were changing from the old to the new order of things. The American Medical Association had been captured by the extremists, who were attempting to overturn the old order of things by revolution rather than by evolution. Who were those qualified to practise medicine: the medical scientists or the medical practitioners? While they needed the medical scientists it was necessary that they had the medical practitioner as well. In England they defined who should practice medicine. There it was stated that a man having definite qualifications was entitled to practice, and many of these men were eligible to appointment in various governmental works and public health work. The insurance companies there only recognized such men. With regard to fees Dr. Strohbach said he had been in correspondence with the Economic League of Leipsic, Germany. He learned that in that city there were used various forms or blanks for the examination work. A given amount of money was paid, the amount depending upon the number of questions to be answered, the amount of work required in the way of laboratory work, etc. There were, he believed, five varieties of fees. The idea of making a medical examiner an adjuster was new, but it appealed to him. But the medical examiner must be fair to both his acquaintance and to the company in whose employ he was. He of course represented the company. How the plan suggested would work out he said he would like to know.

Some Considerations of the Risk in Life Insurance Examinations, with Special Reference to Tuberculosis.—Dr. Clarence L. Wheaton of Chicago read this paper and gave a résumé of some of the principles of the subject with special reference to tuberculosis.

Election of Officers.—*President*, Dr. W. E. Grant, Louisville, Ky.; *First Vice-President*, Dr. Charles T. Cutting, Seattle, Washington; *Second Vice-President*, Dr. Frank W. Foxworthy, Indianapolis, Ind.; *Third Vice-President*, Dr. Paul Fitzgerald, Newark, N. J.; *Fourth Vice-President*, Dr. Wesley Wilbur Beckett, Los Angeles, California; *Secretary*, Dr. G. Strohbach, Cincinnati, Ohio; *Treasurer*, Dr. Liston Homer Montgomery, Chicago; *Executive Committee*, the Ex-Presidents.

CONNECTICUT STATE MEDICAL SOCIETY.

One Hundred and Nineteenth Annual Meeting, Held in Hartford, May 24 and 25, 1911.

Dr. Frank K. Hallock of Cromwell, President, in the Chair.

A Farm Colony for Alcoholics in Connecticut.—Dr. Frank H. Barnes of Stamford said that the problem of how to care for inebriates was one of the greatest of the present time. The laity, with a few members of the medical profession, had been struggling with this question for many years, and very little had been accomplished, inebriety having been on the increase at an alarming rate. He thought, therefore, that something should be done to stop its ravages. In order to get some statistics on the subject to present to the society, he had sent some letters asking for information to the judges of the courts of the leading cities of the State. The answers to these had led him to believe that the best solution of the problem lay in the establishment of a farm for inebriates. He suggested that power be given the president of the State Medical Society to appoint a committee to present this matter to the State Legislature and ask for the appointment of a commission to investigate the subject.

Dr. Henry S. Noble of Middletown believed that a certain percentage of the younger class of inebriates could be cured, if taken in hand with right methods before self-respect was lost. He considered the cure of inebriety to be a sort of moral reformation, enabling a man to withstand the temptation to drink. The punitive methods hitherto adopted had been entirely unsuccessful; because an individual suffering from the acute effects of alcohol, if confined, was almost certain to repeat his offense on regaining his liberty. While the speaker had not unbounded faith in the success of a farm for inebriates, he thought it the best scheme that had yet been devised.

Dr. Thomas D. Crothers of Hartford referred to the curious fact that this was the third time that this question had come up before the State Medical Society. He hoped that this time the work done on the two former occasions would be continued with better success, as the need of it was growing greater. He considered this question to be really one of preventive medicine, and offered a resolution that a committee be appointed to bring the matter before the State Legislature.

Dr. Frederick B. Downs of Bridgeport thought that one reason why a bill to establish a farm for inebriates had not already passed the State Legislature was that many of its members felt that the State Reformatory should take this class of cases, as it had been established to take care of all reformable cases, whether due to alcohol or not. He himself, however, believed that it would be better to have a farm for drunkards, where the men could be put to work.

Dr. Barnes thought that it would be dangerous to mix up alcoholics and criminals, and said that this was also the general opinion of men of experience.

The resolution of Dr. Crothers was passed by the Society, and a committee was appointed.

The Serum Reaction in the Diagnosis of Syphilis.—Dr. Jessie W. Fisher of Middletown detailed the advantages of the Noguchi modification over the original Wassermann reaction and stated the value of the positive reactions, especially in neurology. She then considered the disappearance of the reaction following the use of 606, and made a plea for the early diagnosis and thorough treatment of syphilis. She suggested that the test for syphilis might be made by the Board of Health laboratories. She summed up the value of the serum diagnosis of syphilis as follows: "It makes possible the early diagnosis and treatment of syphilis. It is corroborative of the clinical symptoms. It is invaluable in the differential diagnosis of obscure disease. It is an index to the progress of recovery, and a guide to marriage. It gives an assurance of cure. It is extremely important in the retrospective diagnosis of syphilis and in the prognosis of latent syphilis. Combined with the cytoanalysis of the cerebrospinal fluid, it is diagnostic of dementia paralytica. It is probably destined to become one of the most valuable tests of the future, exceeding in importance the Widal reaction."

Dr. Charles J. Bartlett of New Haven thought that no one had a right to take up this work unless he could give to it at least one day a week, and unless he had great patience and technical skill. In the case of a properly carried out positive test in this country, he considered a physician justified in pronouncing the case syphilis. If the reaction was positive in any great percentage of cases of malaria, he thought it important for the medical profession to know it. In the case of a negative reaction one could not state that the patient had not the disease, it being absent in only 80 or 90 per cent. of the cases that gave a negative reaction. Occasionally a negative reaction had

been found in the active secondary or tertiary stage of syphilis. One should, therefore, be guarded in considering a negative reaction as an indication of cure; although a gradual decrease in the degree of a positive reaction was valuable as an indication of improvement. It was necessary to wait months, and perhaps years, before being sure that 606 had cured the disease.

Dr. FISHER said that Noguchi had stated that if positive reactions were found in nonspecific disease, he would consider the technique faulty; although he admitted that such reactions were occasionally found in malaria. With the Noguchi modifications Dr. Fisher had obtained a lower percentage of positive results than she had obtained with the original Wassermann reaction. She thought that mercury affected the reaction more than 606, and believed that physicians should wait before giving up mercury and potassium iodide.

Ringed Eruptions in Skin Diseases and Their Differential Diagnosis.—Dr. JAMES D. GOLD of Bridgeport stated that ringworm was the disease *par excellence* for ring formations. He considered two forms: ringworm of the general surface, or tinea circinata; and eczema marginatum, or tinea circinata cruris. Both of these were due to a vegetable parasite, tinea trichophytina. Psoriasis and pityriasis rosea were often confused with ringworm; but the large scales of the one and the wrinkled, yellow center of the other marked the difference. He said that the circinate syphilide must also be considered in making the diagnosis of ringworm. The tubercular syphiloderm was confused with psoriasis and lupus vulgaris but the more general eruption and silvery scales of psoriasis, and the chronicity of true lupus, would generally make the diagnosis clear. Lichen planus and impetigo contagiosa were not infrequently found in rings; yet, even then, their individual characteristics were so marked that no trouble would usually be experienced in making the diagnosis. Erythema multiforme was a more acute and inflammatory disease, and was usually readily recognized. One should study the individual lesion, and compare it with other lesions of the body, to make the diagnosis sure, and, having established that, the treatment could be conducted along the right lines, with comfort for the patient and success for the physician.

Dr. MARK S. BRADLEY of Hartford referred to another skin disease prone to occur in ring-like configuration besides those given by Dr. Gold. This was dermatitis herpetiformis, which, in the erythematous type, closely resembled a generalized erythema multiforme. The most striking case of ringed eruption that he had ever seen was in a man with a well-marked case of psoriasis of long standing. The eruption was typical enough, except on the abdomen. The umbilicus was surrounded with a circle, about four inches in diameter, which was solid with the eruption. Around this circle was a ring of healthy skin, about an inch and a half broad; and just external to that was a ring of the eruption, about two inches broad. The abdomen looked like a target in a shooting gallery. The speaker also called attention to the fact that syphilis is the greatest of imitators.

Dr. RALPH A. MCDONNELL of New Haven expressed surprise at the general attitude of the profession toward skin diseases and said that the physician who would utilize the latest diagnostic aids to clear up the etiology of such an uninteresting complaint as chronic headache would dismiss with a glance and a prescription for a stock ointment almost any skin case. He stated that pathological processes of the most varied character might be seen in the human skin.

The Feeding of Sick Infants.—Dr. CHARLES A. GOODRICH of Hartford stated that the object of this paper was to emphasize certain clinical observations concerning the feeding of sick infants, rather than to dwell upon the science of their nutritional needs. Various substitutes for milk feeding in illness were mentioned, such as cereal decoctions, albumin water, a sugar solution and whey; and the low food value of these, as ordinarily prescribed, was pointed out. The special classes of cases in which they were most useful were discussed, together with certain contraindications for their use. Intolerance of milk was then considered, that occurring in disease, and also that due to some inherent peculiarity present in the infant. A brief mention was made of some of the symptoms occurring in this condition, and the feeding of these cases was outlined. Cereal gruels, either plain or dextrinized, were recommended in such cases. Lastly, the increasing importance of the subject of feeding in surgical cases was alluded to.

Dr. H. MERRIMAN STEELL of New Haven said that he had frequently fed babies with summer diarrhea on well-cooked cereals, nearly as thick as the ordinary breakfast foods, and, he believed, with much better results than those obtained by using the weak cereal waters. In cases in which it was necessary to starve the patient for twenty-four or forty-eight hours, he considered water alone the best thing to give, attention being paid to the salts. He agreed with Dr. Goodrich in his recommendation of milk sugar as a proper food for tiding over acute cases, and thought that for rectal feeding dextrin in solution probably furnished more absorbable material than any other food at one's command. He referred to the fact that in adding milk sugar to whey the limit of tolerance for sugar might easily be overstepped; because whey itself contained over 4.7 per cent. of their ingredient. He thought that undue stress was often laid upon the character of the stools in convalescent cases of summer diarrhea. This he considered absolutely no contraindication to beginning milk feeding. A trial of buttermilk was suggested for cases of intolerance for milk in both sick and healthy infants.

Dr. WALTER G. MURPHY of East Hartford said that it had been found that children after the age of three or four months often did better on a mixture of milk and barley-water than on one of milk and water or any other diluent. Its food-value, however, was so little that, if long continued, the patient might suffer from a lack of nourishment. In acute irritative diarrhea the indications were to get rid of all irritating substances in the intestinal tract, and to withhold all food until the vomiting had ceased. In cases in which the babies had some infection and were overfed plenty of water and rest were indicated; and if these children were not too much depressed, they were better without food. In acute fermentative diarrhea, if the child's condition would warrant it, the speaker approved of the withholding of all food until the intestinal tract had been cleared of fermenting substances. In babies whose general condition had not been good, whose powers of resistance were below normal, and who were subject to frequent attacks of diarhea and vomiting the withdrawal of all food was frequently disastrous. If the stools were offensive, cereal foods, either plain or dextrinized, given to the extent of the digestive capacity, were necessary.

Dr. GOODRICH said that a good many children that were ill with acute maladies other than digestive disorders would be able to digest food at a much earlier period than it was usually given to them, provided that the doctor knew what kind of food to use. While he agreed in the main that the children that were exhausted were the ones that especially needed these food values, he felt a little more inclined to the early feeding of the acutely ill.

The Relation of the Medical Profession to Opticians.—Dr. HENRY W. RING of New Haven stated that in the passage of so-called optometry laws throughout the United States the help of the medical profession had been so-

licited with no small degree of success. This aid had been obtained through misrepresenting the possible and actual evils to which the public might be subjected. Many physicians would send their patients to opticians for examination and treatment of the eyes, forgetful that opticians bore the same relation to the ophthalmologist that druggists bore to the general practitioner. A large number of cases of serious disease of the eyes had been treated by opticians with glasses, the real trouble not being suspected. The eye being not only subject to diseases peculiar to itself, but also participating in and giving evidence of affections of the other parts of the body, anyone unacquainted with this relationship was bound to make mistakes. The measurement of errors of refraction and anomalies of accommodation and of ocular motility, with or without the aid of drugs, was not, the author said, a simple mechanical procedure, but represented one of the most important therapeutic measures in the practice of medicine. The oculists had shown more activity than the general practitioners had in opposing the extension of the optometry legislation, because unfortunate results were so frequently met with in their work; but this opposition should not be confined to them. The situation should be appreciated by the profession in general.

Dr. E. Terry Smith of Hartford remarked that if the general practitioners saw, as the men practising opthalmology did every day, the results of the advice of incompetent opticians, they would realize the danger to the community. Until these men were more careful in appreciating their limitations the State should withhold its support of their work.

Dr. Henry S. Miles of Bridgeport said that the opticians had been deceived by a few leaders into believing that they could properly examine and treat eyes without any medical training. They, in turn, had deceived the public and, he regretted to say, some doctors. He did not consider it beneath the dignity of physicians to protect the public against themselves, or to prevent this evil, as well as all other evils. That the opticians had been permitted to continue their peculiar methods so long was equally the fault of laymen and physicians.

Dr. William H. Carmalt of New Haven said that he could not forget the amount of mischief he had seen done in previous years by these men in attempting just what they wanted to get the Legislature to legalize. Not only were they ignorant of the subject of disease of the eyes, but they also did not even know how to fit glasses ordinarily. If the opticians gave their examinations free, they must sell glasses, in order to pay for the loss of their time, whether these were needed by the patients or not.

Dr. Everett J. M'Knight of Hartford thought that the two defeats that the optometrists had had in Connecticut would deter them from trying it again, and believed that this agitation would gradually die out. He doubted whether they could get such laws passed in any more States. Both the Senate and the House Optometry Bill had been rejected without any opposition. It was only by combined effort, he said, that the medical profession of the State could have accomplished what they had during the last year. He remarked that it had been difficult to get the ophthalmologists to appear before the Legislative Committee. He considered this their duty, however, and thanked Dr. Ring for having done his duty in this respect.

Dr. Ring said that he had felt the same reluctance that the other ophthalmologists had in coming before the committee to oppose the opticians, because it would be natural for the unthinking public to say that the oculists were looking out for their own interests. He doubted, however, that the income of the average oculist would have been affected by the passage of these bills.

(To be continued.)

Medical Items.

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the weeks ended June 10 and 17, 1911:

DECAPSULATION OF THE KIDNEY IN THE TREATMENT OF CHRONIC BRIGHT'S DISEASE.*

By JAMES TYSON, M.D.
PHILADELPHIA, PA.

TWELVE years have elapsed since George M. Edebohls published his first paper on the treatment of Bright's disease by decapsulation of the kidney, in the *Medical News* of April 22, 1899. The paper was entitled "Chronic Nephritis Affecting a Movable Kidney as an Indication for Nephropexy." The operation was suggested by the favorable results following in four of six cases in which he had performed nephropexy for the purpose of anchoring a movable kidney in the presence of well-marked chronic Bright's disease. In five of these six cases nephropexy was done without any idea of influencing favorably the chronic nephritis known to exist; the indication for operation being solely the presence in an aggravated degree of the usual symptoms due to mobility of one or both kidneys. The effect of the operation upon the coexisting Bright's disease was simply hazarded in view of the necessity of relieving the patient of these intolerable symptoms. The first case was operated upon on November 29, 1892, the fifth on April 1, 1897.

The complete and permanent disappearance of albuminuria and casts from the urine and the restoration of enduring and perfect health of three of the five patients led him to advise bilateral nephropexy in his sixth patient, a sufferer from chronic Bright's disease complicated with movable kidney. He operated on this patient mainly with the object of influencing the chronic nephritis. The operation was performed January 10, 1898, and "consisted in extensive decapsulation followed by fixation of both kidneys." As a result, the patient, a girl, aged twenty years, was radically cured of her chronic Bright's disease and remained so to June 3, 1904. She has since married, and on July 6, 1903, gave birth to two fine boys. "At the time," Edebohls says, "the idea that the cure of chronic Bright's disease in these cases was mainly, if not altogether, due to correction of the position of the kidney dominated my mind. Further experience, however, and observation made on the occasion of second operations gradually evolved the conviction that the decapsulation was mainly responsible for the good results obtained." Up to the end of 1902 he had operated on 51 cases of chronic Bright's disease, all of which but 3 he had the rare good fortune to follow up to the date of his paper in the MEDICAL RECORD, March 28, 1903. Edebohls continued his operation, publishing results from time to time, culminating in his book on the "Surgical Treatment of Bright's Disease," published before his death in 1904.

Three years prior to the publication of Edebohls' first paper, that is January 4, 1896, Reginald Harrison published in the *Lancet* a paper entitled "A Contribution to the Study of Some Forms of Albuminuria with Kidney Tension and Their Treatment." In this paper Harrison reported 3 cases of operation with resulting cure. In the first he cut down upon the kidney of a youth, aged eighteen years, who had had scarlatinal nephritis, expecting to find a suppurating kidney. Instead, he found a kidney distended by inflammatory products, and he closed the wound under the impression that he had made a mistake in diagnosis. There was a free discharge of blood and urine for several days. The wound was lightly plugged with lint, and in the course of ten days had completely healed. After the incision was made the excretion of urine became far more abundant and the albumin gradually and completely disappeared.

In 1887 he operated on a man, aged fifty years, under the impression that he had a stone in his right kidney. There were colicky pains, hematuria, and later constant albuminuria. He cut down upon the kidney, made an incision through the cortex, and explored the pelvis with his finger, without finding a stone. There was a discharge of blood and urine which continued a long time, but on the withdrawal of the drainage tube the wound healed and the urine became quite normal.

In 1893 he operated upon a woman, aged forty-four years, who had had slight hematuria at times for a year, and occasional albuminuria. Shortly after he saw her she had an attack of influenza, followed by an aggravation of her renal symptoms, including pain on pressure, with increased and constant albuminuria. As she believed that she had passed a calculus some months earlier, Harrison thought he was justified in exploring. He found the left kidney swollen and very tense. There was a free drain of urine with some blood, which continued for a fortnight, when the wound healed. At the date of the report the urine was normal and the patient quite well.

Reviewing these cases, Harrison concluded that the first case was one of scarlatinal nephritis, the second of nephritis from exposure to cold, and the last of subacute nephritis following influenza. *In all*, he said, *the cure was effected by relieving the tension*. He concludes with a few words as to the nature of the operation which might be appropriate in cases of suspected kidney tension and as to the time and occasion of its application. The operation advised was that usually adopted for exploration of the kidney by the finger through a small transverse lumbar incision. It should "be reserved," he says, "for cases where there is evidence that the recuperative power of the kidney suffering from nephritis

*Read before the Association of American Physicians, May 9, 1911.

is overweighted. Where, after an attack of this kind, the albumin is not disappearing from the urine, and there is a prospect, unless some relief is found, of permanently damaged kidney resulting, then a trial of this expedient may be undertaken without adding to the gravity of the circumstances." It will be noted that the operation thus recommended is not decapsulation, but simply section of the capsule of the kidney, the object being to relieve the tension of the organ within the capsule.

The following cases under my own observation illustrate the application of the treatment:

Case I.*—Fannie W., aged nine years, born in Philadelphia, was admitted to the Hospital of the University of Pennsylvania, November 11, 1902. She had scarlet fever when four years of age (five years before admission). During and immediately after the fever she had no dropsy. One year after, however (four years before admission), she presented symptoms of acute nephritis, including albuminuria and general anasarca, which responded promptly to treatment at a hospital in New York City. Subsequently to this she had five relapses, for which she was treated at different hospitals in Philadelphia, with more or less complete recovery, each attack requiring more time to overcome it. The last relapse set in about two weeks before she consulted me, when she had general anasarca with ascites, albuminuria, and casts. The edema was extreme. The face was so swollen that the eyes were almost closed, and the abdomen was enormously distended with fluid. She was sent to the University Hospital, where the examination was completed. Her temperature was 99° F., the pulse 126, the breathing rate 28. There did not appear to be much fluid in the pleural cavities, and the lungs were normal. The cardiac action was feeble; there were no murmurs, but the second aortic sound was accentuated. The liver outline was difficult to obtain because of the ascites, but seemed normal. The urine on admission was acid in reaction, specific gravity 1016, and contained one-half its volume of albumin; there was no sugar. The microscope found pale granular, medium granular, and dark granular casts; also free fatty renal cells. The quantity secreted during the first twenty-four hours was twenty ounces. The blood examination found 45 per cent. of hemoglobin, with 6,320,000 red corpuscles—probably an erroneous estimation.

The patient was immediately put to bed on a milk diet, and ordered cardiac tonics, with eliminative treatment by saline cathartics and hot packs. The remedies acted as they were expected to, and some relief to symptoms followed, but it was incomplete. On November 18, paracentesis abdominis was done, but on account of a defective instrument only six ounces of a clear fluid were withdrawn.

Under treatment the urine secreted was increased at one time to thirty ounces, and there was some diminution in the anasarca, but it was only temporary. Paracentesis abdominis was done repeatedly, with the removal of a clear spring-water liquid, and so persistently did the ascites return that some concurrent cirrhosis of the liver was suspected. She became very much reduced in strength, and after all medical treatment had been unavailing and it seemed she must die unless something else was done, she was transferred to the wards of Dr. Frazier, January 11, 1903, for operation, which was done on January 13, a large accumulation of abdominal fluid being first removed. She was so weak that it was thought unwise to operate on both kidneys at once, and accordingly at the first operation the right only was decapsulated.

The immediate effect of the operation was truly astonishing. In the first twenty-four hours after it was done the quantity of urine secreted was only 21½ ounces, but in the second twenty-four hours it reached 42½, in the third 72½, in the fourth 102, in the fifth 63 ounces, and in the sixth 60 ounces. In ten days after the operation ascites and anasarca had entirely disappeared and continued absent up to the present time. Before the operation the volume of albumin was one-half; but by the middle of February it had fallen to one-tenth of the volume of urine tested. For three weeks prior to the second operation the patient was allowed to be up and about, after which the albumin largely increased, becoming almost as large as when she came under observation. The casts did not disappear, but continued quite numerous up to the date of the second operation.

On March 14, 1903, just two months after the first operation, the left kidney was decapsulated by Dr. Frazier. Surgically the case progressed rapidly to healing of the wound.

After the second operation, the urine, of course, did not increase as it did after the first, as there was no edema to drain off, but ranged from 30 to 60 ounces in the twenty-four hours. Four days after the operation the albumin measured one-sixth volume, with hyaline and pale granular casts. About April 2 the patient was allowed to get up, but almost immediately the albumin increased to one-half volume, and she was promptly returned to bed (April 6). Since that time there has not been any marked reduction in the quantity of albumin; in fact, it has remained about the same. The urine has, however, been secreted freely, and the casts have been mainly hyaline and slightly granular. The patient has again been allowed to get up, and has remained free from dropsy and was, in fact, the picture of health. It cannot be said that there has been a cure, and it is impossible to say that there will be. On the other hand, there can be no doubt the patient's life has been saved, and apart from the urinary evidences she is seemingly well.

She was last seen September 23, 1903, when there remained one-third volume of albumin and a few hyaline casts in the urine, but she was the picture of health. She continued in apparent good health for more than a year, when, having returned to school during a very severe winter, she relapsed after exposure and died. She did not come under our care again.

The original report of my case to this association, at its meeting in May, 1903, elicited reports of four cases, all of which were greatly benefited by the operation, although one, after decided improvement, died in the third month after operation. One was reported by Dr. McPhaedran of Toronto, and three by Dr. Cutler of Boston.

Case II. I first saw Wm. M. in consultation with Dr. Wm. Hammond, at Glenolden, near Philadelphia, May 8, 1910. I found a boy, aged fifteen years, who, although swollen and distorted in appearance by an omnipresent general anasarca, was not confined to bed. His eyes were almost shut by the swelling, the scrotum and penis were invaded, and there was effusion into the abdominal cavity and pleural sacs. I have rarely seen a patient in a worse plight. There were, however, no retinal

*This case has already been reported to the Association at its meeting in May, 1903.

or uremic symptoms, no hypertrophy of the left ventricle. There was slight accentuation of the aortic second sound.

The urine had not been measured, but was evidently reduced in quantity, was loaded with albumin, becoming almost solid on boiling. There were numerous casts, granular and hyaline. There had been some dull pain in the lumbar region. His appetite was good, bowels regular. His discomfort was surprisingly small. He had the waxy pallor of a case of chronic Bright's disease. He was born in Canada, but has been living near Philadelphia for the last seven years, and attended school until three months ago. He had measles when a young child and scarlet fever three years ago, a light attack. Apart from these ills he has been strong and well.

His present illness began apparently suddenly February 13, 1910, the first symptom noted being swelling of the face, extending in a few days to the feet and legs. The edema spread rapidly, but the boy was not put to bed until the first of May; then it was difficult to keep him there. When I saw him the edema was so great that I advised multiple incisions for immediate relief and urged him to enter the University Hospital, which he did on May 31, in much the condition above described. The pulse and breathing were slightly accelerated and the temperature a little elevated for several days, due probably to cellulitis in his legs. His tongue was coated and breath foul. There were no cardiac symptoms except slight accentuation of the aortic second sound. There were a few fine crepitant râles at the base of the lungs anteriorly and posteriorly. Below each scapula there was impaired resonance with feeble breathing sounds and diminished tactile fremitus and vocal resonance, indicating some fluid in the thoracic cavities. The dome of the abdomen was tympanitic to percussion, but there was dulness in each flank, indicating some ascites. The edema was, if possible, worse than when I first saw him. The scrotum was excoriated from friction against the thighs. The legs bore the marks of incisions which I had advised to relieve the tense swelling of the extremities. The superficial veins were distended. The walls of the thorax and abdomen were also infiltrated with serum. The liver and splenic dullness was normal.

Uranalysis. The urine was scanty—6 to 16 ounces, acid in reaction, turbid, straw-colored, and with specific gravity 1016; highly albuminous, containing 8 grams per 1,000 by Esbach's method, and free from sugar. It contained many hyaline and granular casts, a few leukocytes and casts, and numerous cylindroids.

Blood. There were 2,690,000 red cells, 31,000 white cells, and the hemoglobin measured 55.5. On June 3 the albumin was four-fifths by volume and 12 grams per 1,000 by Esbach. On the 4th the blood pressure was systolic, 115 mm.; diastolic, 50. The right leg was so distended that a number of punctures were made with instant relief. These symptoms continued with unimportant modifications from day to day. Between June 12 and July 1 several deep-seated abscesses developed in the thighs and legs and were opened. They were treated in the usual way and rapidly healed, notwithstanding the terrible condition of his limbs. The urine continued highly albuminous, and in addition to granular and hyaline casts were waxy casts and fatty granular renal cells. There appeared also on the legs and thighs, in addition to the edema, an interesting distention of what seemed lymphatic vessels, and there continued more or less fluid in the pleural sacs and abdomen.

The usual measures of treatment were adopted, including salt-free diet, without any permanent effect on the dropsy and secretion of urine, which continued scanty. Having exhausted all of our resources without effect, he was transferred, on August 7, to the surgical wards, and on the 8th both kidneys were decapsulated at one sitting by Dr. A. C. Wood. At the time of transfer the blood contained 3,180,000 red blood cells, 12,000 leucocytes, and 55 per cent. hemoglobin. The capsule was incised and slipped back by the fingers, but not cut away.

The case did well after operation, most striking being, as usual, increased diuresis and correspondingly rapid disappearance of the edema. He was returned to the medical wards on September 16, when the urine was reported having a specific gravity of 1007, precipitating a dense cloud of albumin by heating and acidifying, and measuring by Esbach's albuminometer 1 gram in 1,000. There were hyaline, granular, and oil casts, with granular fatty renal cells and leucocytes; no blood cells. The other organs appeared normal, the heart as to size and position, and without murmurs, although the resident physician's notes mention marked accentuation of pulmonic second sound—probably an error. On the 22d he was up and about the ward, anemic, as attested by the blood examination, which revealed red cells, 3,200,000; white cells, 171,000; hemoglobin, 55 per cent.; but free from dropsy and feeling well. By the 26th he was out upon the lawn with a blood pressure of 100 mm. systolic, and 72 diastolic, and on October 22 he was discharged. October 2, 1910, free from dropsy or other external signs of disease. His urine, with specific gravity of 1013, still contained a considerable amount of albumin, though greatly less, with hyaline and granular casts, granular fatty cells, and leucocytes.

The patient was last seen April 8, 1911, apprenticed to a carpenter and working every day.

Case III. Mary K., aged seventeen years, born in Russia, was admitted to the University Hospital December 28, 1903. Her mother died at thirty-two of heart disease; her father, living at thirty-eight, has pulmonary consumption. She has two sisters and a brother living, the latter possibly phthisical. Mary was eleven years old when she came to America, and went to school until she was fourteen, since which she has been employed in a shirt factory, working hard but trying to live a regular life.

A year before this admission, November, 1902, she was in the University Hospital in my own service for three weeks with tonsillitis and pharyngitis with enlargement of external cervical glands. Her urine then contained one-eighth volume albumin, but no record of a microscopic examination seems to have been made. More recently she was in the Pennsylvania Hospital with tonsillitis and penumonia, and after her discharge she continued ill at home some time longer. Her present illness may have dated from her first admission to the University Hospital, when she had a little albuminuria, but she has been more positively ailing since she had pneumonia. Since then only did her face and feet become swollen, and she was further disabled because of weakness and frequent headaches. Since then, too, she has had more or less cough with mucopurulent expectoration. She has been more ill in the last two weeks, and for a week has been in bed because of great weakness, abdominal pain

and vomiting. The bowels have been regular, but of late the urine has been at times scanty, with occasional frequent micturition. Menstruation, established at fifteen, has been regular and painless until three months ago, when it ceased to appear.

On admission her temperature was 100°, pulse 108, breathing 18. She appeared a fairly well-developed girl of seventeen with moderate edema of the face and slight pretibial edema. Her chief complaints were weakness, headache, cough and some abdominal pain, frequent urination, and scanty urine. These symptoms had been present for about two weeks.

The urine at this time was scanty, with specific gravity 1030, and albuminous to the amount of two-thirds its volume. There were hyaline, pale granular, dark granular, and oil casts, and free fatty renal cells; also globular and squamous epithelium.

Physical Examination. Lungs: There were some moist râles with bronchovesicular breathing, slightly increased vocal resonance, and impairment of percussion resonance in the right infraclavicular region, which proved temporary. The heart appeared normal in size and function, perhaps slightly accentuated as to its aortic second. The pulse was slightly accelerated, of somewhat higher tension than normal. The liver was enlarged and tender, strikingly so; the spleen was normal. The region of the right kidney was tender and apparently the seat also of some active pain. There were no retinal symptoms.

It will be noted that the edema in this case was not great, but in other respects she had the typical symptoms of a chronic parenchymatous nephritis, and she was so regarded.

The usual treatment failed to produce much if any effect on the symptoms. It included the saline diuretics, such as citrate of potassium; also digitalis and digitalin, theocin, caffeine, iodide of potassium, and phenacetin for the headache. The treatment was continued over two and one-half months without making any impression. The largest quantity of urine secreted in any one twenty-four-hour period was 43 ounces; the smallest, 18 ounces.

Satisfied that we had done all possible by medical treatment, she was transferred to the surgical wards on March 11, 1904. On March 12 Dr. Charles H. Frazier decapsulated both kidneys at one sitting. The blood pressure during the operation ranged from 105 to 130 mm. For some days succeeding the operation there was fever with abdominal distention, for which repeated search, including laying open the wound, failed to find a cause except necrotic tissue in the edges of the wound. Ultimately these symptoms disappeared and she was discharged April 16, 1904, with the following note:

General condition good, wounds in fair condition; sinuses small and shallow; urine practically unchanged at discharge as compared with its state on admission.

Over seven years have elapsed since this operation was done and we have kept more or less in touch with the patient ever since. She was said to have been in the Pennsylvania Hospital for a short time in 1904, but a careful search fails to find the history of such admission. On December 19, 1905, she was working in a store at Nineteenth and South Streets, and feeling entirely well without recurrence of her previous symptoms.

On November 12, 1908, Mary was admitted to the Pennsylvania Hospital in my service. She reported that for the last six weeks she had been fairly well and working. She had a little edema of the face, but more of the feet and legs, and a trace of albumin in her urine with a few hyaline casts, but her appearance was not that of an ill woman. She had from time to time complained of a good deal of pain in the left side, but nothing to explain it was found except at this examination a little enlargement of the spleen. In a day or two the edema had disappeared and she was discharged. Occasion was taken to examine her eyegrounds at this admission, and they were found normal. Blood pressure systolic was 120; diastolic, 70.

On June 29, 1909, she reported that she was moderately well and able to work a part of the time. Occasional edema of face and feet; sometimes short of breath. She is neurotic and disposed to answer all questions affirmatively. Since then she has been in the University Hospital a couple of times and in the Pennsylvania a couple of times, to rest up, as it were, always with benefit. She has also reported to me personally from time to time.

On July 13, 1909, she called, complaining of weakness. There was then a good deal of albumin and there were numerous moderately granular and hyaline casts and leucocytes. Two months later she again reported, complaining of headache; the urine continued about the same. She reported November 27, 1909; February 3, 1910, and July 13, 1910.

On January 14, 1911, she called, looking remarkably well. There was no edema and had been none for four weeks. On February 23, seven years after the operation, she reported that she had been remarkably free from swelling most of the winter, but at the date of her visit she thought there was a tendency to return when on her feet, but at the time of her visit she was totally free from it. Yet the urine contained much albumin and a few hyaline casts. She had not menstruated for four months, and had had a good deal of backache.

This case of Mary K. requires some comment. It will be remembered that, while she presented distinctive symptoms of chronic parenchymatous nephritis which did not respond to treatment, she did not have any of the alarming symptoms which endanger life and sometimes demand prompt interference. The case was, therefore, somewhat different from Cases I and II, and also in that the operation was not needed to save life, but was done simply because of the intractibility of the case by any other treatment. Nor can it be said that any astounding change followed the operation. It is true the patient improved and resumed her occupation, and now, more than seven years afterward, continues to work, although somewhat irregularly. She is, however, far from cured, and some may question whether the improvement which took place would not have occurred without the operation. I am inclined to think, however, that had she been left alone, or rather to medical treatment, she would have retrograded. I do not desire to claim for the operation more than is due it, but I should be inclined to repeat it in a similar case.

The following case, sent to me by Dr. J. Langton of Shenandoah, Pa., was, I think, operated on too late:

Case IV. Frank C., aged thirty-two years, a practising lawyer, came of a typically robust family, and was never sick except slightly with rheumatism until present illness appeared. The rheumatism referred to was a mild attack of short duration in June, 1909. He consulted me May 28, 1910.

In November, 1909, he assisted at a fire, became thoroughly wet, changed his clothes in a cold room,

and felt chilly after it. A couple of days later he had a slight headache, which soon passed off, but returned again some time afterward with great severity. These attacks continued increasing in frequency and severity until he consulted me May 28, 1910. They occurred more frequently in the morning, sometimes passing off when he went into the open air. At any rate, their tendency was to abate as the day advanced. Vomiting sometimes occurred with them, but often he had headache without vomiting. If he vomited he ejected whatever was in his stomach; after a meal whatever he may have eaten. The attacks of headache were much more frequent than those of the vomiting. On cross-examination, I found he had morning sickness some months prior to exposure to the fire, so that probably the beginning of his illness antedated the fire.

He tires easily of mental and physical work, and has grown weaker. He is inclined to feel cool, although perspires all the time; realizes a sense of pulsation through the body at times, more particularly after excitement. There is no edema anywhere, in the hands, feet, or face, but he is pale and anemic. He is always thirsty, and his urine is increased in quantity. His blood pressure was 250 by Potain's sphygmomanometer.

Physical Examination.—His heart was enlarged, beating powerfully at the normal site of the so-called apex beat, but also very strong in the nipple line. There was sharp accentuation of the aortic second, but no murmur. The lungs were normal. The urine amounted to five pints in twenty-four hours and had specific gravity of 1008 to 1012, acid reaction, and contained one-third its volume of albumin; no sugar. I suspected sugar because of his thirst. There were numerous hyaline pale granular and dark granular casts.

He grew steadily worse, and on July 12 he came to Philadelphia to be under my care. He was in a desperate condition, suffering with intense headache, nausea, and vomiting. The urine gradually diminished until it had almost ceased to be secreted. For fifteen days, with the assistance of Dr. Holmes Walker, I did all I could to relieve these exhausting symptoms. Purgation, sweating, enteroclysis, hypodermoclysis, salines, digitalis, theobromine derivatives were all tried faithfully without effect. At a consultation, at midnight of the 27th, with A. C. Wood and Dr. Walker it was decided to decapsulate the kidneys. The operation was done at 2 P. M. the next day, bilateral decapsulation being done. The operation was apparently well borne and his condition seemed good when I left him at 3 P. M., but he died at 8:30 P. M., apparently of asthenia. He apparently lost a great deal of blood at the operation. The kidneys as seen after decapsulation were typically granular organs.

It is plain from a study of the above cases that in no one instance was a complete cure effected, for in none did the albumin completely disappear from the urine, notwithstanding the hale and hearty appearance of the patients at certain stages after the operation. These results are not as favorable as those of Edebohls. Of 72 cases on which he operated up to the end of 1903, 43 survived. In these the interval between the date of the operation and the last observation ranged between seven months and eleven and one-half years. Of these cases, 14 are reported by Edebohls as "ideal cures," with the urine normal and patient in excellent health. In three others "practical cure" or "probable cure" is reported and the urine is described "practically normal."

I will not pretend to explain these differences, but, notwithstanding the fact that I can report no cures, I claim that the operation is so serviceable in certain instances that it ought to be done more frequently. The conditions which demand it are not far to seek or difficult of recognition. They are simply these: Stubborn persistence of symptoms causing great inconvenience or danger to life; such are permanently obstinate dropsy, which refuses to yield to the ordinary treatment thoroughly carried out; uremia manifested by convulsions or other unmistakable signs, such as intense headache; anuria and large albuminuria, resulting in anemia and loss of function and strength. I repeat that operation should not be considered until medical treatment has proved unavailing. There are other conditions also in which the operation is indicated, and in the presence of which life has been saved by it. Such are obstinate hematuria, perinephritis with miliary abscesses, hydronephrosis, and pyonephrosis.

In none of these have I had the operation done. There is, however, another condition in which I think it is indicated and serviceable, as attested by my personal experience. It is perinephritis, a condition in which the true capsule, that remaining after stripping off the pericapsular fat, is the seat of depressions and cicatricial markings, and is attached with more than the usual firmness to the substance of the kidney. This condition, at times at least, produces the same symptoms as a stone in the kidney, and has been found at operation done for supposed stone. The presence of this condition may be reasonably inferred when the *x*-ray has proved negative and the symptoms of stone persist. I have had decapsulation done for this condition more than once with satisfactory results.

On the other hand, there are conditions which are said to contraindicate the operation. Age is one of these. An age of fifty years or over would appear to be unfavorable or be attended at most with partial relief, and that for a short time only. Valvular disease of the heart associated with irregularity of action is regarded as contraindicating the operation because of danger from the anesthetic. On the other hand, the hypertrophy of the left ventricle, which is so invariably a complication of chronic nephritis, is said to be benefited and the heart to return to its normal size. Extensive cardiovascular changes militate against the operation. Once established, they constitute a cause of danger which is irremediable, and a study of Edebohls' cases goes to show that those least benefited include cases of this kind. Retinitis albuminuria is also considered a contraindication, because the presence of this condition means that a patient thus affected is almost sure to die in a year after its recognition. It is most important that the intractibility of the case must be established by sufficiently close study. I have myself disadvised operations in cases where inexperienced surgeons desired to operate.

As to the rationale of the cure, the first explanation to suggest itself is the effect of the operation in relieving tension or pressure on the affected kidney. Reginald Harrison, in his original paper, says that in all those of his cases reported "the cure was effected by relieving the tension." It will be remembered that his operation was not decapsulation, but simply section of the capsule of the kidney, which would reasonably be expected to produce the same result.

Edebohls claimed that by removal of the impervious capsule proper an opportunity is created for

the formation of new vascular connections between the blood vessels supplying the secreting structure of the kidney, on the one hand, and the blood vessels of the tissues surrounding the kidney on the other. He even suggests the possibility of the regeneration of secreting structure after its destruction by inflammation. He regards the possibility of such regeneration as established by the experimental studies of Charles Thorel.

To such vascular formation Edebohls ascribes the later or more permanent beneficial effects, claiming, too, that its possibility has been experimentally proved. He ascribes the immediate benefit to such manipulation of the kidney as is necessary in conducting the operation, amounting, he says, to a *massage* of the kidney. He does not accept Harrison's explanation that the immediate good effects of decapsulation are due to a relief of renal tension, because he has never in any of his operations seen such abnormal tension. He considers that the "immediate stimulation of the existing blood supply of the kidney thus effected (by manipulation), supplemented by the relief to congestion afforded by the direct abstraction of more or less blood from the organ during operation, suffices for the immediate wants of the kidney, and carries it along until the supplementary new circulation becomes established." I can conceive the relief to the congestion to be of some value; in fact, I can see no difference between congestion and tension, and what is a relief to one is relief to the other. I deem it hardly profitable to prolong this discussion of the rationale, but those who desire to do so can find more about it in Edebohls' book on the "Surgical Treatment of Bright's Disease."

A few words in conclusion as to the new capsule which invariably forms sooner or later in from ten to twenty days after decapsulation. This is admitted by everyone who has studied the subject experimentally on animals, and confirmed in the few instances in which a second operation has been done on the same patient. The point of difference is as to the presence of vascular communication between the capsule and the surrounding tissues, the presence of which would explain the permanent improvement. From such an examination as I have been able to make of drawings made to illustrate experimental papers I would decide in favor of the probability of such vascularization.

The question has been raised, and it appears to me with reason, whether there is any advantage in decapsulating both kidneys. It will be remembered that in my first case one kidney was decapsulated some time before its companion, and that little additional effect followed the second operation. Finally, the operation should be a skilful and rapid one. The conditions of the operation are such as to make it prolonged under any circumstances, and it should not be further prolonged by the slowness of the operator. On this account, too, it is most important to determine whether the decapsulation of one kidney does not answer the purpose as well as the bilateral operation, thus cutting down the time one-half.

In my experience, not very large, the cases most favorable for operation have been those of chronic parenchymatous nephritis, and those in which the most brilliant results appeared have been those associated with stubborn anasarca. On the other hand, Edebohls says the most satisfactory cases for operation are cases of chronic interstitial nephritis, while Ramon Guiteras disadvises operation in cases which suffer from anasarca.

There has been a good deal of theoretical objection to this operation because of the tendency of the capsule to be restored and the absence of evidence of a new blood supply thus furnished, although certain experimenters do claim such a supply does succeed the operation, and furnish drawings from actual specimens to show that this is actually the case (Ferrarini, quoted by Edebohls in "Surgical Treatment of Bright's Disease," p. 113). But "the proof of the pudding is in the eating," and if improvement, attested by a number of clinicians and surgeons, takes place after operation, it does not very much matter whether it comports with the anatomy and physiology of the kidney as at present understood or not. It is unfortunate but true that many well-determined results succeed therapeutic measures which are not explainable.

A comment likely to be made by those who are familiar with the facts is that this operation has not made much impression on other surgeons than Edebohls, and that it has fallen into disuse rather than become more general. In the first place, this may be only partially true, and the operation may have been done more frequently than would appear on the surface, since, succeeding the report of my first case at the meeting of this association in 1903 four cases were verbally reported—one by McPhedran of Toronto, and three by Cutler of Boston—all of which were greatly benefited by the operation. Another reason for infrequency of operation may be the fact that most of these cases originate in the practice of physicians as contrasted with surgeons, and as the former are usually more timid as to operations they are less likely to have recourse to the surgeon for help. This circumstance, too, makes the surgeon less familiar with the operation and its good results. Thus, in the case of one of my most satisfactory cases it was with some difficulty I could get the surgeon interested in the operation, but after he operated and saw the brilliant result he was astonished, and since then has looked altogether differently on it and is ready to perform it whenever I want it.

1506 Spruce Street.

THE PROPER ATTITUDE OF A CORPORATION TO ITS INJURED EMPLOYEES.

By JOHN F. CULP, M.D.,

HARRISBURG, PA.

In these modern days of social and industrial unrest, when one hears so much about the war between capital and labor, it is rather refreshing to read how these often opposing forces may be brought to work together to the mutual advantage of both. An article by W. H. Allport, M.D., in *The Journal of the American Medical Association*, November 12, 1910, tells how one Illinois corporation has dealt with the question of industrial accidents from the standpoint of compensation furnished to the injured employees.

The writer of this article, who has been for the past twenty-two years surgeon to one of the largest Pennsylvania corporations, would like to refer briefly to the policy pursued by this company and its method of management of accident cases. This corporation is not a coal mining company; many of its nine thousand employees, especially in more recent years, have been foreign-born, but the general average of intelligence is quite up to the standard usually found among the employees of similar concerns.

Almost from its beginning this corporation has

adopted a policy of dealing directly with its injured employees or their families, without the intervention of attorneys or other third parties. In this policy we have been singularly fortunate. The money paid out has almost invariably gone directly to those who need it most, namely, the injured and their dependents.

In order to bring about such a desirable result the injured person must be first convinced that his employer is his best friend, who stands ready and willing to do what is right and just without being forced to such attitude by the intervention of a lawyer or the threat of litigation. It is impracticable and perhaps impossible within the scope of an article such as this to tell the various details which are necessary to carry out such a policy.

In a general way, however, when a man is injured we look after him until he is well, and in case he cannot be made well provide for his future and that of his family if he has one. Should he be killed outright or die as the result of his wounds we provide for those who are dependent on him for support.

The question of our legal responsibility is rarely referred to, because that is subordinated to the needs of the individual. All expenses incident to the surgical care of the injured one are paid by the company and the patients provided with the best care, either in a hospital or in his own home, if suitable, and no matter what his financial condition may be the injured pays nothing for medical or surgical services. He is given to understand that the company wants him to get well and assumes the moral responsibility for his care and attention.

The legal phase as to whose fault the accident was due is seldom discussed, except in special cases, nor referred to by the representative of the company in the first instance, although, of course, we know our legal status, whether it be that of non-liability, uncertain liability, or clear liability. We assume that there are certain dangers incident to such employment, and while we endeavor to safeguard such work, accidents are bound to happen. To expect the injured one to shift for himself, to be a burden either on his relatives or the community, is neither just nor right in principle, and is bad as a matter of policy.

When a man is injured, as soon as practicable after the injury his financial condition is inquired into, and it is learned who, if any, are dependent on him for support. In many cases he is given a sum of money weekly during his incapacity equivalent to half his earnings; in other cases, when the family is large and the wages small, he is given full pay or a greater proportion than one-half pay. In many cases of single men sent to the hospitals and who have no dependents the money allowance does not begin until they leave the institution, and then a sum of money sufficient to pay their expenses while they are convalescent is given them. Just as soon as they are able suitable work is found for them. Often one who has been hurt in one department will be given work in another, because no suitable work can be found for him in the department where he was injured.

It frequently happens that the usual wage of the employment to which he is assigned is not as large as that of his former position, and in such case the wages are often increased. Several factors here enter into the adjustment of the wages. The first consideration is his needs, the second his fidelity and time in service, and the third whether he himself was to blame for the accident.

There are many jobs about the works that can be acceptably filled by men who are either temporarily or permanently disabled. While in most instances the new position does not pay so well as the one held before the injury, yet it often happens that an accident gets a man better wages than he was getting before. Frequently men of foreign birth, unable to speak a word of English at the time of being injured, have acquired a fair knowledge of our language during the many long weeks and months spent in the hospital. Such men are often given better work than they could have ever hoped to have gotten had they not been hurt.

After an injured man returns to work we seldom if ever require that he sign a release before he is re-employed. Occasionally a man who has been injured and has been given money leaves our employ. If then he returns to work he is required to sign a release if he has not done so before.

In case of a fatal accident, if there be a widow and children a pension is provided. Here, too, there is no fixed sum for every case. The amount is regulated by the individual needs. This pension, which is paid monthly, varies in amount from one-fourth to two-thirds of the regular average pay of the husband and father for the previous two years.

The length of time this pension is continued varies. In some instances the time of the continuance of the pension is fixed in advance; in other cases the life of the pension is determined by the needs of the pensioners. If the children are sixteen years of age or over and healthy it is assumed that they can take care of themselves. For boys of this age positions are found in the works. Should the children be under sixteen years of age the mother is given a certain fixed sum monthly for each child until it reaches the age of sixteen years, and after this time it is expected that the child will be able to care for itself.

It frequently happens that the mother prefers to have one or more children placed in some industrial school or college, so that they may obtain a better education and training than she could give them. In this case the company makes all necessary arrangements for their admission. Should the widow remarry, her pension ceases. This pension is conditioned on her good moral behavior and the proper care of her children. Should a son who has been wholly or partly supporting his parents be killed we endeavor to find the extent of this support and to provide for its continuance for a reasonable length of time. Such pensions or reimbursements are often difficult to arrange satisfactorily. Under the Pennsylvania law parents are entitled to compensation for loss of support in such an amount as the child was contributing at the time of the death or injury and would have been likely to continue to contribute. In case of a minor they are entitled only to such compensation as they might have received from him during his minority. Should the son be over age the parents must prove not only that they had a right to expect support from the son, but that the family relation still existed, that it was likely to continue to exist and that they actually did receive assistance and the amount thereof. In the interest of harmony and to promote and maintain good feeling among our employees the company interprets such claims liberally, and in a few cases they have knowingly allowed themselves to be imposed upon rather than work a seeming hardship or be involved in litigation.

While pecuniary assistance is necessary to the injured and their dependents, there are many other

ways in which real aid can be extended. Humane and kindly interest and sympathy combined with practical helpfulness are essential not only in serving the injured and the afflicted family, but as a part of efficient service to the corporation. It helps the dependents forget that corporations have no souls if they find that the representatives' hearts are filled with sympathy. Such attitude is always appreciated. It is here that the surgeon has a great opportunity to be a real help not only to the injured and his dependents, but also to the corporation that employs him. It is he that first comes in contact with the injured, and if he be kindly and considerate, a man of broad humane sympathies and of good judgment, he can be of the greatest service to all concerned.

While he is healing the stricken he may also comfort the distressed, and if he possesses that rare tact born of genuine humane impulses he can pave the way to more kindly feeling on the part of his patient and his family to the corporation. Just as every man is born with certain inalienable rights, so does practically every man who is injured think his hurt is caused by the carelessness of some one else, and frequently it is wise by quiet acquiescence to permit him to think so for a time. Later, when his mind is clearer and his wounds less acute, he can generally be brought around to the proper point of view. If the surgeon gives the injured man or his distressed family then to understand that the employer does not intend to limit the treatment of such employee or his family to its legal liability, but will do what right and justice dictate should be done, the problem is nearly solved.

The results of this policy which I have outlined are as follows: During the twenty-two years that the writer has been the surgeon of this corporation there have been twenty thousand recorded cases of accidents. When we consider the hazardous nature of the work and the large number of workmen, this number of accidents, many of which were trivial, is rather under than over the average. From these twenty thousand accidents only eight suits for damages against the company have resulted, six for personal injuries and two brought by widows on account of the death of their husbands. These cases resulted, not because the company stood on its legal rights, but because the dependents had visions of large damages to be recovered, and in some instances could not be persuaded to compromise even by their counsel. That this company permits itself to be sued only where all other efforts fail is shown by the results of the cases. Of these eight cases, five were tried in the county courts, and in each case a non-suit was given the company. One of the cases was settled out of court, one withdrawn, and one, brought by a foolish, irresponsible boy, is still pending. This is a record probably unequaled by another large corporation in this country, and shows what can be accomplished by a policy of fair treatment such as has already been outlined. These results have been achieved without the aid of either a claim agent or a legal department, and while the surgeon is always at liberty to consult a legal adviser, such a recourse has been comparatively seldom necessary. While definite figures are not available, it is safe to say that not more than five thousand dollars have been spent for legal services in connection with these twenty thousand accidents that have occurred during the past twenty-two years. The money went where it did the most good; that is, to the injured and their families.

Absence of litigation, however desirable, is not the only good to be derived from the carrying out of such a policy. The employer says in effect to the employee: "I recognize the fact that you are helping me to create wealth, and if adversity comes to you in the shape of an accident it is only fair that some of this wealth that your hands helped me to create should be yours. I will care for you and yours." The law may not compel this, but whether it does or not it is right and just. Such a spirit of fair and generous dealing cannot but have a far-reaching and lasting effect on the employee. It makes him a better and more loyal workman and is conducive to pleasanter and more harmonious relations between him and his employer. The value of such harmonious relations between master and servant is difficult to estimate in dollars and cents, and in these days of industrial unrest, when capital is preparing to capitulate to labor on the best terms obtainable, the corporation that can stand forth with such a record over a long period of years must perforce have a great advantage.

The criticisms and strictures by Dr. Allport on the treatment of injured and disabled workmen by Pennsylvania corporations, I fear, have been largely too true in the past. It is such treatment that has been wholly responsible for the employers' liability law of 1907, one of the most drastic liability laws of any State in these United States. This law has been in operation in Pennsylvania for the past four years.

While this policy of treatment to the injured workmen and their dependents, as above outlined, is more nearly ideal than any other method, yet it is not without its shortcomings. Its advantages are: That it deals with each case individually, and, while there are certain fundamental principles observed, each case is decided on its merits. It makes the individual needs paramount, loyalty and length of service, while considered, being secondary. It makes the attending surgeon, who comes at once into intimate personal relations with the injured, the general agent of the corporation. It eliminates the claim agent and the paid attorney, or, rather, it makes of the attending physician all these and a family counselor as well.

The disadvantages are: Loyalty and long service cannot amount to so much in time of accident as the industrial necessities. The man who has been frugal and saving gets less in proportion than the man who has been improvident and careless in his living. The needs of the latter are greater because he has saved little or nothing, and it would seem, therefore, that the saving, frugal man was in a measure taxed to help out his unfortunate but less deserving brother. The second disadvantage of this policy consists in making the surgeon not only the healer of the wounds, physical and mental, but also the claim agent and legal counsel as well. It makes so much depend on the tact and temperament of the surgeon. Medical schools can and do teach medicine and surgery, but rare tact born of humane feelings can only be gotten in the great school of life, and if the physician does not have the proper temperament to begin with it can never be acquired.

Now that the writer has given up this work for other not more congenial but less exacting, it is pleasant to review the past just a little, and while sadness and some sorrow have been inevitably linked with most of his work, yet many of the clouds have at times shown a silver lining.

One of the five cases above referred to that were

tried in the courts was that of a middle-aged German, who brought suit for loss of an eye. He was employed to chip castings, and one day a chip from a fellow workman's chisel flew off and struck him in the eye, so that the eye had to be removed. Unfortunately, the poor fellow was almost entirely blind in the other eye, the result of an injury in childhood. He had a wife, who was an epileptic, and one child. The company gave him a pension equivalent to eighty per cent. of his wages, which were small, and coal and wood in addition. This pension was given voluntarily, was unlimited as to time, and as he had a nice little house worth twelve hundred dollars, paid for out of his savings, it seemed to us that he could live comfortably.

Some months after a labor agitation lawyer from the western part of the State persuaded the man he was being badly treated, and advised him to bring suit on the ground that the employer should have provided him with a wire cage in which to work so that flying particles could not reach him. The action was brought during my absence in Europe, and the trial was brief. The poor fellow lost his case and the sheriff sold his house, and between the cost of living and the lawyer he was left penniless. His wife died from grief, and some friends, of whom the writer was one, took up a collection and sent him and his son to the Fatherland. Six months later the priest in the town where he lived received a letter from a German priest asking if the man had a legal right to marry, saying that a buxom widow with fifty thousand dollars wanted to marry him. So they were married, and, as the story book says, it is presumed they lived happily ever after.

Many similar cases, with their touch of humor as well as pathos, could be told, but they are not strictly to be included within the confines of an article such as this.

In conclusion, the writer not only hopes but predicts that the principles of humanity and justice which have been applied in the treatment accorded to its employees by this one Pennsylvania corporation will be incorporated into a law which will do much to lighten the burden of the industrial workers in time of accidents.

211 Locust Street.

THE DRINK HABIT, WITH SPECIAL REFERENCE TO OFFICE TREATMENT.

By CHARLES A. ROSENWASSER, M.D.,

NEW YORK.

From time immemorial the doctrine has been preached that the victim of the drink habit cannot be successfully treated for his affliction unless he be restrained in a properly equipped sanatorium. Through the promulgation of this false idea thousands have gone on to insanity or ruin, and an uncountable amount of suffering has been inflicted upon innocent women and children. That the doctrine is false is my conviction based upon the experience gained through several years' trial of treatment of the drink habit by office visits.

The sanatorium idea is founded upon three accepted facts. First, that the essential factor of treatment of the drink habit is to keep alcohol from entering the patient's system; second, that owing to impaired will power the inebriate is unable to resist the temptation to take the drink which he so strongly craves; and, third, that this craving must be subdued in order that the weakened will can assert itself and cure occur.

Though correct in theory, it fails in practical application, and in my opinion such treatment will eventually be supplanted by the more rational and more easily applicable plan of treatment by office visits. The results obtained by such a plan of treatment show conclusively that the drink habit can be cured in as large a percentage of selected cases by office treatment without restraint, or with but a few days' restraint (during the acute stage), as by any other plan, provided the treatment is begun in time and is properly conducted.

Undoubtedly the sanatorium is an absolute necessity in dealing with some types of inebriates, such as those individuals, usually periodical dipsomaniacs, who during the acute attacks are practically temporarily insane, and in dealing with those advanced cases or alcoholic mental defectives who must be placed under restraint for their own protection and for the protection of others. In practice we find that before an individual will consent to place himself under restraint in an institution, or before his family can be brought to see the necessity of removing him from his home, or before a court or jury will commit him to an institution, conditions are usually so bad that the likelihood of cure, under any plan of treatment, is extremely remote.

Exponents of the sanatorium speak enthusiastically of the importance of isolation from alcohol, and the great value of systematic outdoor and indoor work, bathing, regular living, etc. That all these measures possess decided therapeutic value cannot be denied, but can they be applied in dealing with private patients. It is seldom possible to keep alcohol away from the individual who wants it, provided that he is able and willing to pay for it. Hence the vital principle of the restraint idea rests upon sandy soil. As a class, private patients requiring sanatorium treatment for the drink habit are not amenable to rule or reason. Inebriates possessed of sufficient insight to realize the importance of leaving no stone unturned to overcome their affliction and who are therefore amenable to reason and willing to obey instructions can be presumed to be willing to be cured, and can be cured by office visits, without detention, if at all.

Some inebriates develop in time a sanatorium habit and wander from one institution to another. They are a class of people for whose existence there seems to be no excuse. Of no use to themselves and a menace to their families, they are veritable social parasites, and sanatoria seem to be their natural habitat. They either cannot or will not obey rules and regulations. If they could or would they would probably not be incurable inebriates.

In dealing with public patients, such as is contemplated in the proposed Board of Inebriety for New York City, conditions are somewhat different. Patients legally committed to an institution such as an industrial colony can be subjected to more or less discipline, and, though such labor is a decidedly uncertain quantity, a competent director could probably show some of these blind-seeing people "light through work." Under the comprehensive plan of treatment outlined by those experts in social welfare who were instrumental in having the law passed the outlook is much brighter than heretofore for this class of individuals.

Were private sanatorium treatments all that could be wished for they would still fall far short of the mark, in that they are available only to those possessed of worldly goods. They are expensive, and, as earnings cease, as a rule, during the period of

treatment, the treatment becomes doubly expensive. The sanatorium idea has therefore been a great obstacle to the progress of the rational treatment of the inebriate, and has been responsible for the foisting upon the public of so-called "cures" and wonder workers. Such cures have only sprung up owing to the slowness of the medical profession to recognize the fact that there is a great need and popular demand for a plan of treatment for the drink habit which can be carried out without placing the patient under restraint, or removing him from his home and business, and subjecting him to the expense of institutional treatment, and the environment of an inebriate asylum.

Office treatment meets these requirements. Its most potent factor lies in enabling us to get the cases early, before the nerves and organs have suffered irreparable injury and while the home is still intact and the patient is employed, these social factors being of vital importance in establishing a cure.

The worker in the field of inebriety sees various types of cases, and, while, of course, individual cases present individual features, there is a certain similarity which permits of their classification into groups. For practical purposes we can arrange five such groups. They will be briefly considered.

Group 1. This includes the large number of persons who, while attending to their usual vocations, are daily consuming a small amount of alcohol in some form, and who have the drink habit without knowing it. They do not get drunk in the ordinary sense of the word, they do not stagger or lose control of themselves perceptibly, but they are more or less braced up by alcohol much of the time. They are usually considered to be moderate drinkers, and almost never apply for treatment for the habit. They are of interest, however, as representing the army from which the true inebriates are recruited.

Group 2. This group comprises persons who have gradually developed from what are commonly called moderate drinkers to more or less constant heavy drinkers. The individual may or may not get perceptibly drunk at times, but it is plain that he is drinking too much. He begins to grow neglectful of himself and his affairs, does not keep his business appointments, and is prone to forget his obligations to his family and to society in general. It is for the members of this group that office treatment holds out the greatest hope.

Group 3. This group is composed of those inebriates who are subject to periodical sprees, and who between the attacks are usually sober citizens, total abstainers, in fact. During the spree it is usually necessary to overlook their wishes and deal with them as we would with any patient bereft of his senses. Restraint is often necessary. This can sometimes be accomplished by keeping the patient under the care of an intelligent nurse for a few days, or placing him in a hospital. When the attack is over most of these patients are as well as they ever will be, irrespective of the treatment applied, for periodical dipsomania is usually a manifestation of epilepsy or manic-depressive insanity, and complete recovery is decidedly rare. For many of these patients office treatment is of value, however, for they can in some instances be taught to live so that the attacks will be less numerous and less severe, and also how to foretell the onset of the attack and to return at once for treatment on the first indication that an attack is imminent. This class of patients will tax one's patience to the extreme, but the condition is by no means hopeless. If we but get the patient to return to us in the hour of trouble and lessen the attacks and shorten their duration we will have accomplished something worth working for.

Group 4. This group is composed of inebriates who have become unable to manage themselves or their affairs. More or less drunk most of the time, they are a menace to themselves and to society. They are the individuals we see drunk upon the streets or in our police courts and jails, if they are poor, or leading wild and riotious lives and spending days and weeks in drunken revelry if they are rich. These are the patients demanding custodial care, for whose families sanatoria are a blessing. For some of the members of this group detention over a period of years under legal commitment on a compulsory labor farm holds out a faint hope.

Group 5. This group consists of inebriates who fail to provide for their families, beat their wives, and otherwise misconduct themselves. They are, of course, subjects for the police, but ought in every instance be put through a thorough mental examination, for many of them are utterly irresponsible and ought to be placed in insane asylums. Prolonged detention, under legal commitment, on a compulsory labor farm holds out practically the only hope for some of these individuals.

In every case our first duty is to study the patient and try to discover the underlying cause for the condition. This having been ascertained, common sense dictates that we aim our treatment at correcting the fault. Some of the most common causes of the drink habit are: Neurasthenia, diabetes, faulty heart action, intestinal parasites, gastric and intestinal catarrh, wasting diseases (especially tuberculosis), mental disease, excessive smoking, improperly prepared or insufficient food, worry, poverty, and prosperity. How many of these causes are removable?

Be the underlying cause what it may, the individual comes to us, complaining of a vague, indefinite thing, a more or less powerful physical and mental demand—a craving—for a stimulant. Not infrequently he says, "Relieve me of this intense craving for the stimulant and I will leave it alone." Can we promise him the relief he begs for? We certainly can in a most encouraging number of instances.

In practice we find that in the vast majority of cases we are unable to locate any definite cause for the craving for alcohol, and we cover our ignorance, and in a measure placate ourselves and our patients by saying that the patient is a neurasthenic or a psychasthenic, or both, and we are compelled to treat him along broad general lines. This, in fact, is what we should do, for from a practical standpoint the treatment of the drink habit in most cases resolves itself into nothing more nor less than the treatment of a severe case of neurasthenia.

In the treatment of this condition the following plan (published in the *Journal of the Medical Society of the State of New Jersey*, February, 1909) has given me most encouraging results:

I urge the patient to stop drinking at once, assuring him that under the treatment the craving for alcohol will soon become less severe and in a day or so will disappear, and that "tapering off" only prolongs the agony and is indeed like cutting off a dog's tail by inches. At the outset free purgation is secured by compound cathartic pills, fortified with podophylin, and the bowels are kept loose for a few days. I give atropine, grain 1-100, and push it to the point of toleration and maintain it there about four days, then give a small dose twice daily for the

remainder of the week; extract of digitalis, one-half grain, three or four times daily for two or three days, then diminishing the dose gradually and discontinuing at the end of the week, unless indicated; arsenious acid, grain 1-20, three times daily for a few days, then twice daily for the balance of the week; ergotin, four grains, three times daily for two or three days, then two grains twice daily for the balance of the week; and, occasionally, in the presence of severe prostration, one-half to one dram of the fluid extract of coca-erythroxylon, repeated as indicated. Other drugs used as indicated during the first week are bromides, chloral, sulphonal, trional, veronal, paraldehyde, apomorphine, calomel, quassia, and milk of magnesia.

During the second and third weeks the patient receives fifteen grains of the red extract of cinchona suspended in glycerine and water night and morning. Beginning with the fourth week and continuing for several months, he receives a tonic pill containing phosphorus, strychnine, iron, arsenic, quinine, and cascara.

Systematic treatment being a prime essential for success, I have my patients report to me three times daily for the first two or three days, then twice a day for the balance of the first week; during the next two weeks they report once daily and during the fourth week every other day. They then call once a week for a month, then once in two weeks, then once a month for as long a time as they will come. Of course the above number of visits will in some instances have to be less and occasionally more, but in the main the general plan is adhered to. Sometimes the patients are treated at their homes, and occasionally one will spend a few days with me. I never tell my patients what drugs they are receiving, and as far as possible give them every dose myself in order to be sure that instructions are being followed and to prevent self-drugging. Naturally we must avail ourselves of every possible aid to secure the desired result. Advising as to the general health and welfare, proper diet, church attendance, sometimes change of occupation (as from a tanner to a floorwalker), etc.

If you find the foregoing plan too irksome, if it would weary you to see your patients so often, or if your time does not permit of such close attention to these cases, and you yield to the temptation to write a prescription for the above or any other drugs and tell your alcoholic patients to take so much so often and see you again in a week or so, you will in all probability not obtain the desired result, for you will fail to secure the psychic touch which is so essential to establish a cure.

In the Medical Record, May 28, 1910, I reported a few cases illustrating the possibilities of office treatment. I am pleased to be able to add at this time that every patient then reported cured has remained well. A few additional illustrations may not be amiss. All the following cases were treated by office visits, without detention.

Case I. T. D. B. Aged 38 years. Married. Editor. Has been a hard, steady drinker for twenty years and would go on sprees. Ordinarily would take fifteen drinks of whisky a day, but when on a spree would take as many as forty. Has had great difficulty in retaining employment during the last year or so, and has just been discharged for drunkenness. Has had several attacks of delirium tremens. Came under treatment February 13, 1905, at the close of a prolonged spree. He promptly responded to treatment, stopped drinking at once, regained his position, and has remained totally abstinent.

Case II. G. M. H. Aged 29 years. Single. Electrical engineer. Referred by Dr. H. V. S. Stout, East Orange, N. J. A mild, constant drinker, with severe periodical sprees, during which he would drink all he could get. Craving was so intense that he carried a flask of whiskey with him. Came under treatment March 10, 1905, having been on a spree for about four months, during which time he has done practically no work. As an evidence of good faith, on beginning treatment he deposited a pint flask of whiskey upon my desk. The result of treatment left nothing to be desired. He is to-day a prosperous man, a good father and husband, and a total abstainer.

Case III. J. S. Aged 51 years. Widower. Painter. Has been a hard, steady drinker since early youth, drinking at first beer to excess, then taking up whiskey and other strong alcohols. The quantity consumed daily was only measured by his ability to get it. Has not done a day's work in months. This case looked hopeless on being brought to me by Rev. Father Polycarp, March 15, 1905, but, as the unexpected sometimes happens, he made a splendid recovery, stopping completely inside of twenty-four hours, and has remained totally abstinent in spite of the fact that he not long ago painted inside of a brewery.

Case IV. F. W. G. Aged 40 years. Butcher. Referred by Dr. W. S. Baker, Newark, N. J. A constant drinker, being more or less braced up most of the time. Easily affected by small quantities. Lays his excessive drinking to worry over domestic troubles. Has a good business and has never stopped work, but has to keep on drinking to get through the day. Is so nervous that he can scarcely talk, and it is very hard for him to use tools. Began treatment May 2, 1906, stopped drinking at once, and when last I heard of him a few months ago he was totally abstinent.

Case V. M. B. Aged 34 years. Married. Salesman. Has been a hard, steady drinker since early youth, taking all forms, but during the past few years mainly whiskey. Has spent some weeks in a sanatorium under treatment for the habit. Dr. A. V. Wendel of Newark, who was familiar with the young man's history, said to me, "That boy cannot pass a beer sign." He began treatment April 13, 1905, stopped at once and remained abstinent for about four months. Having an attack of diarrhea he asked a druggist for something to relieve him. This "something" aroused his craving and he drank slightly for a few days, when he returned for further treatment. He did well for three months and again relapsed, returning for treatment November 18, 1905. Following this course of treatment he remained well for fourteen months. January 18, 1907, he informed me that he had a few drinks the night before. Another course of treatment was begun, and with the happy result that he has remained well.

Case VI. F. M. B. Aged 46. Single. Bookkeeper by occupation, but owing to drink has not been able to do any task requiring mental effort in a long time. Is at present doing odd jobs in a stable and has only earned about thirty dollars in the past six months. Is a hard, constant drinker, drinking as much of any alcoholic beverage as he can get. Has been in the City Hospital several times for alcoholism and has had delirium tremens. On presenting himself July 24, 1905, his condition was such that the most enthusiastic worker would make a

gloomy prognosis. He responded, however, and remained abstinent for about a month, when he relapsed into his former condition and passed out of my sight. Meeting him on the street March 21, 1906, in a deplorable condition, I prevailed upon him to try again. He did so, and the result of treatment was most satisfactory. He to-day occupies a position of trust, has money in the bank, and has remained abstinent over five years.

Case VII. F. G. Aged 30 years. Draughtsman. Married. Brought to me by Rev. Mr. Stewart of Newark. Since four years has been subject to periodical sprees. Would have three or four attacks each year, and they would last about two weeks, during which time he wandered about drinking and neglecting himself and his affairs. Says he has at times a severe fight with himself to keep from drinking in the intervals between attacks. On being brought to me February 12, 1907, he was just over a spree. He has been entirely well since.

Case VIII. H. C. Aged 42 years. Married. Telegraph operator. Brought to me by Rev. Mr. Morgan of Montclair. For the past ten years has been subject to periodical sprees, and they have been growing more frequent, more severe, and of longer duration. When not drinking there is a struggle to keep away from alcohol. On coming under observation September 14, 1909, he was just over a spree and, while not having had a drink in twenty-four hours, had a strong desire and feared his ability to let drink alone without help. Under treatment the craving disappeared and he has remained well.

Case IX. A. F. Aged 42 years. Married. Salesman. In the midst of a spree and practically destitute he applied to a merchant for help. This gentleman, impressed by his manner, sent him to me for treatment at his expense. I learned that for about six years the patient had been addicted to drink, his excess being in his opinion due to domestic trouble. He had lost everything. Began treatment November 27, 1909; responded promptly. The merchant gave him employment and he is doing well.

Case X. E. B. K. Aged 38 years. Married. Clerk. This patient was for some years subject to periodical sprees, but being an exceptionally clever man he managed to retain his position with a leading broker until the sprees came so often and lasted so long that he was unfit for business and lost his position. He then became a fairly heavy, constant drinker, with sprees every month or so. He applied for treatment April 28, 1907. Stopped drinking at once and has remained absolutely well. He to-day occupies a most important position.

Case XI. G. A. J. Aged 33 years. Married. Machinist. This man was a moderate drinker of all forms of alcoholic beverages for about ten years, but for the past year, owing to some unexplainable cause, has been getting drunk several times a week, though he drinks comparatively little whiskey and beer. Craving is not very strong, but he is very nervous. He came under observation July 14, 1909, stopped abruptly, and has remained well.

Case XII. F. B. T. Aged 39 years. Single. Lawyer. Took his first drink of whiskey at the age of sixteen. At twenty-five was a very heavy drinker, getting drunk at times. About two years before coming under observation he spent several weeks under treatment at a sanatorium, following which he abstained over a year, though at times he had a hard time to keep away from drink. About a year later he took Hostetter's Bitters, not knowing it was alcoholic. This awakened the craving and he soon took whiskey, drinking hard, taking about one quart daily. He began treatment April 5, 1906, and has remained totally abstinent since, though there have been times of stress when he had a struggle to keep away from drink, and would I think have relapsed long since were it not that he always returns for a few days' treatment at such times.

Case XIII. E. C. Aged 48 years. Married. Coachman. Referred by Dr. J. C. Mabey, Montclair, N. J. For the past two years has been drinking too much and gets drunk at times. Though he has managed to retain his position, he has several times been on the verge of dismissal owing to neglect of his duties and the fear of accident while driving. Has been told by his employer that he must stop drinking or leave and has made a hard fight to get along without drink, but finds that he is unable to do so without help. Began treatment August 13, 1909; stopped at once, and when last I saw him, a few months ago, he was entirely well.

Case XIV. H. M. D. Aged 24 years. Single. Salesman. Referred by Dr. Morris Manges of New York. He began the use of alcohol socially at the age of eighteen years and, though extremely moderate for several years, gradually increased the quantity taken. For two years has been drinking to excess, getting drunk once every week or oftener and drinking constantly every day. During the six months prior to the date when I first saw him he was drunk more days than he was sober. He says he drinks because he feels the need of a "bracer." Has not attended to business for some time. Under treatment by Dr. Manges he stopped drinking for about four weeks and then resumed, not knowing why. The history of this case, the life of idleness which the young man adopted, the impossibility to get him to interest himself in some definite enterprise, the fact that he had recently inherited some money and was bent upon enjoying life in his own way rendered the outlook in this case extremely unfavorable, but the recovery was prompt, and from the day I first saw him, February 2, 1910, to date he has remained totally abstinent.

Unfortunately, the condition is one which, owing to a number of causes, is prone to relapse regardless of what is done in the way of treatment. In most instances relapse is due to over-confidence on the part of the patient. He feels certain that having remained abstinent for some time he is able to drink in moderation, and he takes a drink of some alcoholic beverage. This soon leads to another and another, and shortly he is again an addict. If he has previously spent weeks or months in a sanatorium miles away the likelihood of going to the trouble and expense incurred in a return to the institution is small, for he is by nature a procrastinator and keeps putting the matter off, and consequently steadily grows worse. On the other hand, had he been treated by a physician nearby who had won his confidence and persistently and diligently impressed upon him the vital importance of returning at once for advice and treatment in the event of things going wrong, the chances are far greater in favor of his return to his physician, thus shortening his days of inebriety and forestalling calamity.

Granted then that nothing can keep alcohol away from the man who wants it and is able and willing to pay for it, and that therefore the aim of the sanatorium in this direction is futile, and granted further that the craving for alcohol can be subdued by office treatment in those patients who are really desirous of overcoming their affliction and will co-

operate with the doctor, and that office treatment is within the reach of practically every person, is it not time for the medical profession to pay thoughtful attention to this phase of a vital subject?

With reference to the value of treatment of the drink habit, without detention, Norman Kerr ("Inebriety," 3d edition, p. 385) expressed himself as follows: "If the inebriate and his friends realized at an early stage of the disease his diseased state it may be laid down as a general rule that the treatment of inebriety would be best conducted with the patient pursuing his usual avocation. To have the mind engaged in the performance of regular duties, to be so busy at one's daily work as to leave no time for thoughts of indulgence, is no mean aid to the therapeutic cure of this disease. The more leisure the inebriate has the longer the time at his disposal to dwell upon his miserable slavery, the greater the danger of frequent repetition of the inebriate act. Mental occupation and bodily exercise are alike invaluable."

In recapitulation and conclusion, I would say that over six years of constant and almost exclusive study of the diseases of inebriety has convinced me that those individuals who are sincere in their desire to be cured of the drink habit can in the vast majority of cases be cured or vastly improved by office treatment without detention, or with but a few days' detention during the acute stage, and that those who enjoy their inebriety and do not wish to be cured cannot be cured or much improved by any plan of treatment. In the minds or brains of this latter class of persons there is either something present which does not belong there and which we are unable to remove, or something lacking, which we are unable to give.

510 West End Avenue.

CLINICAL OBSERVATIONS IN SOME CASES OF PROSTATIC OBSTRUCTION.*

By JAMES PEDERSEN, M.D.,

NEW YORK.

Under the assumption that all clinical experiences are interesting, especially such as present variations, I beg to submit six cases, somewhat atypical in character, in the hope that they will contribute to the discussion that is to follow. The first two two cases will illustrate some of the phases of malignant growth of the prostate and bladder—important phases because unrecognized (if not, indeed, unrecognizable without cystoscopy) until the malignancy has gone beyond the possibility of radical removal.

Case I.—In the first of these, an extensively infiltrating carcinoma, primary in the bladder wall, had given neither pain nor other recorded pathognomonic symptom until a few weeks before death.

The patient, sixty-four years old, in bad general condition, was referred by his physician, July 9, 1910, with the following four-year history: frequency of urination and dysuria, gradually increasing; marked hesitancy finally; occasional attacks of cystitis characterized by cloudy and malodorous urine; blood clots at times, apparently due to catheterism; no actual hematuria. At the time these usual symptoms began to develop, a "very large" prostate was diagnosticated; thus explained, they became the basis for the subsequent treatment. In due time catheter life became necessary. Two years later a sound was passed daily for one year. As may be sometimes observed, urotropin, whenever administered, served only to increase the frequency of urination.

The general symptoms were: an increasing tendency to headache, palpitation, and edema of the feet and scrotum; numbness and tingling of the feet; sudden temporary deafness. Previous personal history, including syphilis, negative. Family history negative as to malignancy and tuberculosis.

No pain had developed until recently. This recent pain was referred to the bladder neck and arose with every urinary desire. Both had been increasing rather rapidly. By the time he came under our observation the pain had become demoralizing and the urinary desire incessant. Hourly catheterism was imperative; it gave him some slight respite in the intervals.

The whole clinical picture spoke for malignancy. Rectal touch confirmed the diagnosis without defining the lesion. The indwelling catheter was not tolerated. Cystoscopy was impossible. The one specimen of urine submitted for examination was "yellow, slightly turbid, alkaline, 1008 and contained some red blood cells, many leucocytes and a trace of albumin, but neither casts nor sugar."

As soon as permissible, after nursing and stimulation for forty-eight hours, suprapubic drainage was established as the only way of relieving the sufferer. The peritoneum over the bladder was found permanently thick and adherent, and the subjacent bladder wall was dense and rigid as far as palpable through the wound. After some dissection, the prevesical space was cleared until a sound in the bladder could be recognized and cut down upon. To our surprise, the prostate had the feel of benign enlargement; it had escaped the extensive infiltration of characteristic feel that involved almost the rest of the bladder. The patient died of exhaustion two days later.

The pathologist described the growth as an epithelioma of the major portion of the bladder wall, beyond which it had extended, almost filling the pelvis and involving the rectum and retroperitoneal lymphatics.

The value of early cystoscopy in every case of disturbed bladder function is supported by such histories as the one just cited. It may well be considered a desirable routine procedure when no contraindication exists, as the likelihood of exciting a traumatic prostatitis is negligible if the cystoscope be introduced properly. Though the earlier recognition of the lesion might not have implied a radical cure necessarily, it would have postponed the fatal termination and spared the patient some suffering meanwhile.

Case II.—The second case, having points of similarity, is suited for comparison with the foregoing. It is remarkable in that the carcinomatous process, though it involved the whole prostate, did not give symptoms, *according to the patient's history*, until three months before so much difficulty in introducing the catheter was experienced, as to portend impossibility of introduction at an early date. It was this approaching calamity that led the patient's physician to advise prostatectomy. Possibly the freedom from striking symptoms is explicable by the fact that the malignant degeneration was of the scirrhous type.

The patient, an intelligent man fifty-six years old, gave a negative previous personal and family history. His first urinary symptom was sudden reten-

*Read before the New York Urological Society February 1, 1911.

tion three months before the consultation on June 15, 1910. Though this retention had been relieved by careful catheterization, infection of the bladder occurred. Subsequently, however, by the skill of his physician, this infection had been gradually cleared up, though catheterism had become necessary at shorter and shorter intervals to meet the increasing inability of the bladder to even partially relieve itself, in spite of the fact that the compensatory hypertrophy of its muscle fibers had not yet become exhausted. Catheterization was necessary from every one to three hours during the day and from three to four times at night. Futile urinary desire with pain and tenesmus set in as soon as maximum distension was reached. Resistance and rigidity of the vesical neck were now so considerable that a metal catheter was being used. Aside from a little blood after this instrumentation, occasionally, no blood was noted.

On examining the patient it was noticed that he looked older than his age, and that he was correspondingly atheromatous. That a soft rubber catheter of any caliber could not be made to enter beyond the membranous portion was quickly demonstrated. A 20 F. natural curve web catheter finally overcame both the spasm of the external sphincter and the binding rigidity encountered throughout the deep urethra.

The history of rapidly increasing narrowness of the deep urethra without tortuous deviation of the canal; the excess of subjective over objective local symptomatology (cystitis being no longer present) and the man's general appearance, though it could have been ascribed to his broken rest for three months past, all excited the suspicion of scirrhous malignancy. This the rectal examination did much to confirm. The rather small, firm, fibrous prostate was felt pushing its apex forward, as it were, along the membranous urethra, thus compressing it.

Two days later, suprapubic prostatectomy was undertaken with the understanding that, if the evidently fibrous gland were found malignant and could not be successfully removed, permanent suprapubic drainage should be established. The intravesical portion of the prostate was found funnel-like, with the large end directed forward, and hard as stone. The strain and pinching pressure upon the enucleating finger were very great. The line of cleavage was readily found, however. With the help of my assistants the truly difficult enucleation was accomplished and a satisfactorily clean cavity was left, as determined by bimanual palpation. The pathologist's report confirmed the diagnosis.

At the end of the first week a blunt sound (23 F.) entered the bladder without being obstructed or deviated in the least. Equally so 25 F. a week thereafter.

He now urinated at will in a good stream. The patient made a perfectly smooth, non-febrile convalescence, and took the train for his home on the fifteenth day after the operation.

Eight days later he wrote that his physician was dressing what remained of the suprapubic wound, and that the only urine it emitted was a few drops during micturition. A month after this he wrote that he now had a good appetite, was gaining strength and had no pain whatever. His letter of January 9, 1911, however, tells plainly of an abdominal metastasis causing gastrointestinal symptoms and symptoms described as "rheumatic." He was obliged to stop work about the middle of December, after almost six months of comfort and fair health. Apparently no bladder recurrence has developed thus far.

What can be done to guard against such masked cases of malignancy? Evidently the case cited was one of insidious obstruction leading to synchronous bladder hypertrophy ending in atony, accompanied by symptoms so slight as to be regarded by the patient as negligible. Only by a system of inspection can such cases be discovered before some ominous symptom compels attention.

Case III.—The third case is that of an active but feeble man of seventy years, who had had prostatic symptoms for between six and seven years. With the usual frequency and hesitancy of urination, this period of his history included an attack of bright hematuria with clots, a year and a half ago. This lasted three days. There was no recurrence until four days before he came under observation. Complete retention having occurred after some sexual excess, he had been catheterized, and again twelve hours later. Thereupon slight hematuria accompanied by frequency and urgency, with pain during and after urination, developed.

A 16 soft rubber catheter entered the bladder; readily though encountering a sense of constriction in the elongated deep urethra. The residual amounted to only ℥iii. Aside from the large amount of blood, with moderately abundant mucus and pus and a correspondingly high percentage of albumin, the urine was negative.

Per rectum, the prostate was felt low down in the pelvis; it was small, soft, and tender. The intravesical enlargement could be palpated vaguely through the relaxed abdominal wall. A tentative diagnosis of malignant growth of the prostate was made. On attempting to pass the cystoscope, the beak of the instrument encountered an obstacle, as though the enlargement bulged into the urethra laterally and from above, apparently at the internal meatus. A guiding finger in the rectum did not help. Eventually the long, slender Freudenburg cystoscope with short beak entered the bladder after some maneuvering. (No anesthesia.) Marked general enlargement was seen, but the distending medium became turbid so promptly that the details of the picture could not be studied. A tissue shred brought away by the cystoscope exhibited only dense connective tissue under the microscope.

Because the hematuria began to abate and all his local symptoms to improve under treatment, he persisted in deferring the operation. The hematuria ceased, but started up again within a month and he consented. Everything considered, the patient was not a good surgical risk. Therefore, forty-eight hours for preparatory nursing in the hospital were planned. But he played truant and entered the hospital a day late. Prostatectomy was performed June 23, 1910. The right lobe was firm and adherent; considerable force was required to enucleate it. It came away in two portions. The left lobe was delivered entire with great ease. A full size sound was passed to identify the membranous urethra and by palpating through the bladder we proved that neither constriction nor obstruction remained. The hemorrhage was so sharp as to make packing of the prostatic cavity desirable. For about three hours he suffered moderate shock. His poor recuperative powers and his obstinate refusal to take sufficient nourishment prolonged his convalescence. In the middle of his second week, during a period of torrid weather, he nearly died of heat prostration. His appetite

failed utterly. His restlessness made impossible anything like satisfactory attention to his dressings. Instead of the usual primary union in the sutured portion of the wound, the wound broke down. His homesickness next became a factor. Only the fear of fatal cardiac overstrain prevented me from yielding to his nagging request to be allowed to go at this time. His fourth week in the hospital, however, was signalized by such positive general improvement that he was permitted to leave, though his suprapubic sinus was still leaking considerably. He began to gain in flesh and strength at once. The sinus did progressively well and was firmly healed within two weeks.

The subsequent course of this case has tended to confirm the tentative diagnosis of malignancy. While progressively improving, both locally and generally, and noticeably gaining in weight and color, he suddenly began to lose weight, ten weeks after the operation. Soon thereafter the hematuria started up again. It has persisted ever since, more or less constantly. Cystoscopy has again presented the same difficulties at the outset, though a soft rubber catheter and a sound enter the bladder without appreciable impediment, and though he empties his bladder to within two drams. The patient has declined a second operation.

It seems to me that this case calls attention in the first place to the necessity for preparatory treatment before the operation. The amount of this preparatory treatment, expressed in number of days the patient should spend in the hospital, depends upon the individual case and is a matter of judgment. Unquestionably this patient had an excessive hemorrhage because his circulation had not been quieted by rest in bed before the operation. Could what was obviously indicated in his case have been carried out as planned, he would have been spared not only the hemorrhage but the shock, which was certainly augmented by the hemorrhage.

Case IV.—The fourth case may be properly entitled one of "irritable prostate." The patient, seventy-five years old, of large physique and fairly good appearance, but with a positively senile mentality, was referred for treatment in March, 1910. A year before he had begun to complain of feeble urinary stream and nocturnal frequency. Soon thereafter he had his initial retention. His symptoms gradually increased, and about a year later, when his second retention occurred, his physician put him on catheter life. This was about two months before he came under my care. A third attack of retention (relieved by his physician) had occurred very recently. He now complained bitterly of an incessant burning at the neck of the bladder, changing to pain whenever the catheter was passed, and of frequent, fitful attacks of vesical tenesmus in the intervals. To get a little relief, catheterization from seven to ten times in the twenty-four hours was obligatory. There was no history of hematuria.

The man's general condition and mentality were at variance, as described. Arteriosclerosis was decided. At 8½ inches a soft rubber catheter found a small quantity of residual urine, thick with pus. It appeared that he had almost stopped drinking water and had greatly reduced his intake of other fluids, hoping to avoid catheterism. His avoidance of fluids and the fact that a little urine was squeezed out during some of his tenesmic seizures, combined to account for the trifling amount of residual urine at that time. A few days later, after the tenesmus had been considerably checked and the patient had been put on the requisite quantity of water, the residual rose to an average of about 5 ounces. The prostate, per rectum, was large, prominent and boggy.

For obvious reasons it was determined to avoid any operation on this patient, if possible. His devoted wife willingly took up the burdensome treatment. Appropriate local measures, aided by small doses of codeine at the outset, soon reduced the catheterism to four times in twenty-four hours and practically put an end to the tenesmus. The incessant, tormenting "burning" at the bladder neck persisted unbated, however, and was the unfailing cause for his peevish complainings. Cystoscopy was easily accomplished without even local anesthesia. Contrary to the expectation, no calculus was found. A satisfactory radiograph by Dr. Lewis G. Cole excluded renal and uretral calculi. Two or three otherwise inexplicable exacerbations of the burning, associated with an abrupt reappearance of an appreciable quantity of pus in the residual urine at the next catheterization, after which would come marked relief, supported the alternative diagnosis of recurrent small follicular abscesses of the prostate, each rupturing in turn. Solutions of silver nitrate, mild below the average, seemed to increase his discomfort without any subsequent beneficial reaction.

Suprapubic drainage was unavoidable. It was advised, with the expectation of a subsequent prostatectomy should the patient's vital condition improve sufficiently. This improvement was not realized, however, though the patient was relieved of most of the prostatic pain—what remained of it being apparently due to the occasional contact of the rubber drainage tube. The patient's mental condition grew steadily worse. A marked degree of general hyperesthesia set in. At night he had delusions, and off and on, both by day and night, exhibited irrational impulses and mild delirium. He died eighteen days later. The urine varied in specific gravity from 1008 to 1020, and showed a faint trace of albumin—not more than the pus could account for. Casts were never present. The excretion of urea (1 per cent.) was proportionate to his diet. There seems, therefore, less ground for attributing his death to nephritis than to the effect upon the economy of the progressive mental deterioration.

Case V.—The fifth case is that of a patient sixty-eight years old, of an unusually sensitive organization. About four years before coming under observation he had developed noticeable dysuria. Two years later his first attack of retention occurred. An evidence of his extreme sensibility is the fact that, though free of constitutional symptoms, he spent nine weeks in bed at this time so that the catheter could be used from two to three times in twenty-four hours, as indicated. At the end of the nine weeks the bladder seems to have regained considerable power and catheterism was no longer necessary. The past two years have been marked by more or less acute attacks of cystitis and urinary difficulty, for which he was given indifferent treatment spasmodically. His general health began to fail, and this fact, coupled with his lack of purpose, made of him a pronounced hypochondriac. In all other respects his history is negative.

At the time he came under observation he complained chiefly of the annoying frequency (every two hours, day and night); considerable burning sensation with every urination; an aching pain in the pros-

tate, and a sense of fullness in the rectum. Made doubly timid by some previous experience and his inherited hypersensitiveness, he dreaded catherization. Apparently it was wholly because of this dread that he had been neglected so long. The catheter did not disclose as much tenderness of the deep urethra as expected; it entered easily and withdrew nineteen ounces of residual urine, the last portion thick with pus and mucus. The history of previous catheterizations made it permissible, in our judgment, to draw off this large quantity at once, and to offset it by leaving in eight ounces of boric solution.

A day or two after entering the hospital he began to show symptoms of renal insufficiency. The practically total retention was met by catheterism so regulated as to avoid overdistention and consequent back pressure. Eventually the crisis was successfully passed, and the deferred cystoscopy was performed (as usual without anesthesia). The findings were: Marked trabeculation of the bladder,—so much so that the ureter mouths could not be recognized; in the upper right-hand segment of the bladder the entrance to a diverticulum; no calculus.

In consultation with his physician, it was decided that prostatectomy, except by the two-stage method, would not be a safe undertaking. The preliminary cystotomy was performed under gas anesthesia. The bladder was drained for three weeks. The drainage was continued for this unusually long period, partly because of the diverticulum and the extreme bladder-atony, but chiefly to allow the kidney function to improve as much as possible before proceeding with the prostatectomy. His recovery was uneventful and satisfactorily rapid. He now urinates at normal intervals without any difficulty or distress whatever, and empties his bladder to within two drams. Under the usual after-treatment, the cystitis is clearing up.

This case certainly affords a strong argument in favor of the two-stage operation in certain cases. It is not a necessary procedure in every case. The degree to which this man improved in all particulars during the three weeks of bladder drainage was very reassuring and made the prognosis good. Instead of an invalid he is now a normal man.

Case VI.—The sixth case was referred three years ago for the relief of an intermittent incontinence, chiefly nocturnal. His early previous history, though not wholly relevant here, has its bearing. It is at least interesting as enumerating several ills to which flesh is heir.

The patient, of temperate habits, energetic and "wiry," was sixty-nine years old. His only urethritis was contracted when twenty-two. During its course he transgressed every rule of general and sexual hygiene. He declared that, after the use of certain strong injections, "the whole urethral lining came out at one time." Be that as it may, the duration of his urethritis was one and a half years. It is perhaps remarkable that neither chordee nor positive symptoms of posterior urethritis can be recorded; the latter especially in view of the pathological condition soon to be described. Next came three attacks of renal colic. After the first (1870) he discharged a grape-seed calculus; the second, twenty years later, did not impress itself on his memory; the third, twelve years later, was made memorable by the discharge of a quantity of sand for a period of twenty-three days. Finally, four years before coming under observation, he developed urinary frequency, hesitancy, and feeble stream. For their relief a physician performed internal urethrotomy. The hemorrhage, described as from 25 to 30 drops, was suggestively slight. Nevertheless, six or seven months later upward curvature developed. During the healing of the urethrotomy wound he passed a sound and made pressure per rectum against it. A year after the unrethrotomy he noted loss of sexual desire. Ever since the operation he had had the symptoms which constituted his chief complaint, namely, irregularly intermittent incontinence, as noted above; a feeling of distention in the rectum, very variable frequency and urgency of urination (from four to twenty times in twenty-four hours), and a sense of discomfort during the urinary act.

After he had suffered thus for two years he sought advice. From his history at this point it is evident that chronic suppuration of the prostate and perhaps of the seminal vesicles was the diagnosis. He declined operation and was given palliative treatment.

Examination showed a small, soft, mobile prostate and two sharply-defined, cord-like, indurated seminal vesicles. Both lateral lobes yielded tangibly to the finger; moderate pressure was sufficient to cause a dram of pure pus to flow from the urethra. When the seminal vesicles were included, the otherwise pure pus was found charged with countless spermatozoa. The residual urine amounted to less than two drams.

Having recently seen a similar case cured of a suppurating focus, I agreed to carry on the treatment and to defer operative intervention. Though not as constant to the prescribed and proscribed lines as could have been wished, he was fairly faithful. To bridge over the necessarily longer or shorter absences from the city, he was taught to empty the pus sacs by means of the Swinburne prostatic massage instrument.

Omitting the vagaries and vicissitudes of his lengthy experience, and noting only the essentials, we have an increase in the residual urine, which now varied from 1½ to 6 ounces; two attacks of retention, only one of which required the catheter; no vesical calculus as proven by cystoscopy; several brief attacks marked by chilliness and fever and sometimes by sweating; and a mild attack of pneumonia. He was under the care of his family physician during these several illnesses. The net results of the local treatment were: No further incontinence except when overtired; a substantial reduction in the frequency and urgency of urination; less pus from the sacs, and a restored potency.

It having become evident that no further progress could be expected, operation was advised. He declined and did not report for eight months. In that time he had retrograded both locally and generally—the latter to an alarming degree. Operation was now accepted. After four days of necessary preparatory treatment, suprapubic prostatectomy was successfully performed, February 21, 1910. The largest pus sac was easily shelled out; the remaining portions were tenacious, owing to the chronic inflammatory changes. There occurred more laceration of the vesical outlet than usual.

Anticipating, therefore, the possibility of a malformation during the healing, the indwelling catheter and the blunt sound were used at proper intervals, beginning five days after the operation. In spite of this precaution, a fold of tissue must have formed, and when the after treatment was taken up at the office it was found that a soft rubber catheter would not enter the bladder unless

styletted and sharply curved, though a blunt sound entered without difficulty.

Fortunately this apparent obstacle did not prevent the patient from emptying his bladder to within five drams of the total. He was last seen on October 20, 1910, at which time the cystitis of many years standing had almost disappeared; the urinary function was normal; his day-intervals varied from two to four hours, depending upon the activity of the kidneys, and he could retain his urine seven hours at night.

THE TREATMENT OF NEURITIS WITH THE HOT-AIR DOUCHE.*

By LEOPOLD STIEGLITZ, M.D.,

NEW YORK.

In opening this communication it might be well to remark that neuritis is a comprehensive term, and that under its caption diseases of very different nature are included. I am speaking to-night of that form of neuritis which presents itself to us in the guise of the severer forms of sciatica or as an inflammation of one or more of the large nerve trunks of the arm, a condition characterized by very severe pains originating in the peripheral nerve, and by more or less disturbance of sensibility in the shape of paraesthesiae or hypaesthesia. This form of neuritis is common enough and presents no small difficulties in the way of successful treatment. These difficulties are due to two facts, which I should like to emphasize at once: (1) After the inflammation in a peripheral nerve trunk has reached the stage of actual organic changes in the nerve structure the disease shows little tendency toward spontaneous recovery; on the contrary, the tendency is all the other way, toward a state of chronic and more or less permanent inflammation. (2) When these organic changes have set in the *curative* value of drug treatment is almost nil.

The main principles of the actual cure of the disease can be summed up in two words: Rest and heat. In the severer cases little or no headway will be made until the patient is put to bed and kept there till he is well on the way toward recovery, and then the return to active life should be gradual and cautious; a premature use of the affected limb is punished almost invariably by a setback. The beneficial effect of rest is indirect, inasmuch as it protects the inflamed nerve trunk from the innumerable small traumatisms active use of the limb would entail, traumatisms which aggravate the condition as indicated by the pain they create. Although rest is a *sine qua non* in the severe cases, rest alone will not cure this form of neuritis, owing, as stated above, to the very slight tendency toward spontaneous recovery of an inflamed nerve trunk. This failure to heal of its own accord is accounted for by the poor blood supply provided for the nutrition of the peripheral nerve trunks, and in general it may be said that the more poorly tissues are fed the more slowly do they throw off inflammatory or other diseased conditions. This is the point at which the second curative factor mentioned, heat, comes into play. For many years I had heat applied in the shape of hot salt or sand bags placed along the course of the affected nerve, and the results obtained were not bad. Nowadays wherever we have the electric current at hand it is well to wrap electrically-heated pads (so called thermopads) about the affected arm or leg and to keep these pads in place for a good part of the twenty-four hours. Hot poultices and other hot applications can be used for the same purpose. Far more effective than any of these methods of applying heat is the use of superheated air. Under the influence of Dr. Willy Meyer's teachings of Bier's methods of treatment of inflammatory conditions, I began using superheated air in the treatment of neuritis two years ago, and the results obtained have been so satisfactory that I thought it worth while to call your attention to this most efficient method of treating this trying class of cases. In neuritis the superheated air is applied best as a hot-air douche along the course of the affected nerve trunk. This method gives decidedly better results than the use of the hot-air boxes, so useful in joint cases. The application is made two or three times a day, or even oftener, according to the severity of the case. Each application should last from half to three-quarters of an hour. Briefly, it may be said that the douche should be applied as hot as the patient can bear it, care being taken, of course, not to burn the skin. After a few treatments the tolerance increases greatly. The amount of heat can be controlled both by regulating the source of the heat and by holding the conducting tube more or less closely to, and moving it more or less rapidly or slowly, over the skin; the closer it is held and the longer the current of hot air strikes a given point of the skin the greater is the sensation of heat. At first I used an apparatus built along the lines of the one described in Dr. Meyer's "Bier's Hyperemic Treatment." The source of heat was either a special Bunsen burner for gas, or, where gas was not obtainable, a special alcohol lamp, both supplied by Kny Scherer. At present I use an electric hot-air douche, which is exceedingly handy and simple, and which at the same time gives off a much higher degree of heat than any other apparatus I have tried. The construction of this electric hot-air douche (made originally to dry hair quickly) is simplicity itself. It consists of a small electric motor, which drives a small fan; the latter forces a current of air over a coarse wire coil heated by the electric current. Within less than five minutes the air as it leaves the conducting tube shows a temperature of 200° F.; this is hotter than any patient will stand applied closely to the skin.

These hot-air applications accomplish two equally important objects: they alleviate the pains, which are the principal symptom of the disease, and at the same time they cure the disease itself. The cure is effected most likely by the production of an active hyperemia, not only in the skin to which the heat is applied, but also in the underlying tissues, including the affected nerve trunks. After an application the skin is very much reddened, and at the end of a week the area is browned as from sunburn.

I do not for a moment wish to claim any miraculous cures from this method of treatment (the process of repair is at best necessarily slow in a profoundly inflamed nerve trunk), but I do not hesitate to assert that this process of repair is stimulated and the course of the disease considerably shortened by the plan of treatment outlined. In the milder forms of the disease, which are fully as common as the severer forms, the hot-air treatment is as near an approach to a specific as I could wish for. Except in very inclement weather the patient need not be confined to his house. The application of the hot-air douche every morning and evening, the wearing

*Read before the Metropolitan Medical Society of New York.

of long flannel sleeves (or drawers) and a certain amount of care to avoid unnecessary use of the affected limb will cure most of these cases.

Before closing with the histories of two characteristic cases, I wish to state expressly that I do not taboo the use of drugs in the treatment of neuritis. The salicylic acid group, many of the coal tar preparations and codein contribute greatly to the *comfort* of the sufferers during their cure, but the latter is just as effective without their use, as I have seen in cases where the patients objected to medicines of any kind. The use of the stronger opiates, notably morphine, is in my opinion absolutely reprehensible.

Case 1: Mrs. B., aged 45. Seen for the first time December 26, 1908. Two weeks before had been taken with very severe pain in the right arm, which had grown steadily worse. She had been under the care of a leading neurologist, who had used electricity and ordered massage and aspirin. The massage had caused excruciating pain. On examination I found a rather frail woman, with a systolic murmur, a moderate degree of anemia (60 per cent. hemoglobin) and a trace of albumen with occasional casts. There was marked tenderness along the course of the musculospiral nerve and above the clavicle from pressure on the nerve trunks of the brachial plexus. Paraesthesiae and a sensation of numbness in the thumb and radial half of the dorsum of the hand and loss of sensibility to touch in the same area were present. The paroxysms of pain were almost unbearable, occurring at all times of the day and night. Use of the arm brought on a paroxysm without fail. The treatment instituted was absolute bed rest, warm electric pads wrapped about the affected arm, but separated from the arm itself by a wire arrangement, as the pressure from the pad was unbearable; hot-air douches of an hour's duration, given three times a day; phenacetin, aspirin and codein in moderate doses, and occasionally veronal. The first two weeks improvement was slow, then there was a gradual but constant and comparatively rapid further improvement, and by February 10th the patient was completely free from pain. Two weeks later, against my advice, she began playing bridge, with the result that a rather severe relapse set in, severe at least in pain. The immediate use of the hot-air douche gave relief within twenty-four hours, and by the 7th of March, within twelve days of the onset of the relapse, she was completely and permanently cured. When she went abroad the following May she insisted upon taking the rather cumbersome hot-air apparatus with her, for fear of a recurrence of the disease.

Case 2: C. L., aged 72, consulted me October 18, 1908, on account of pain in his right arm. He had been suffering from more or less pain for the two last weeks; the last two days the pain had been almost unbearable. Sensation of numbness and tingling in the fingers and hand had been present for some time. The examination showed tenderness along the brachial plexus above the clavicle, and very marked tenderness along the musculospiral nerve. Tactile sensibility on the dorsum of the thumb and index finger diminished. Treatment: Bed rest, the hot-air douche for thirty to forty minutes twice a day, electric pads about the arm. Patient refused all drugs. After five or six days gradual but steady improvement set in, after ten days the patient was up, in two weeks the worst part of the disease was over, and in six weeks from the day the hot-air treatment was begun the patient was well.

REPORT OF A CASE OF OVULATION WITHOUT MENSTRUATION.

By M. J. SIEGELSTEIN, M.D.,
NEW YORK.

The relation between ovulation and menstruation has given rise to a great deal of controversy in the past, and it must be conceded that, although many theories have been advanced for the occurrence of ovulation without menstruation, the knowledge of this subject is far from being satisfactorily understood. It is very rare for young girls to conceive until after the appearance of their menses, and impregnation rarely occurs after the menopause. These facts rendered it natural for earlier observers to suppose that conception could not occur without menstruation. This view, however, was soon abandoned. The physiological interpretation of menstruation and ovulation is a subject not at all clear. It is probable that the rut in animals as well as the menstrual processes in the mucosa of the uterus have some connection and fill a certain purpose in conception or in the embedding of the impregnated ovum. What this purpose is is still vague and uncertain. Some believe that the premenstrual swelling of the mucous membrane is a preparation for the impregnated ovum, a sort of nest formation. According to this view, the occurrence of the menstrual flow would indicate that the nest has been destroyed and that the impregnation of the ovum, for which the nest had been prepared, had not taken place. As Simpson has expressed it, "menstruation is the abortion of an unimpregnated ovum." Contrary to this view, others have seen in this wound formation on the mucous membrane during menstruation a favorable condition for embedding of the ovum. Which of these theories is correct cannot at present be determined, since we do not know whether the impregnated ovum embeds itself in the uterine mucous membrane shortly before or after menstruation. We are better informed about the association of menstruation with ovulation so far as time and cause are concerned, as occasional autopsies performed on women who have died suddenly during menstruation and the examination of ovaries removed operatively show that menstruation usually coincides with the bursting of a ripe follicle. The activity of the follicles in the ovary must be looked upon as the driving force which brings about the menstrual phenomena in the uterus. Without functionating ovaries there cannot be menstruation. Women with congenital defects of the ovaries do not menstruate; those in whom the ovaries have been entirely destroyed by disease or operatively removed stop menstruating.

The manner in which the uterine function is regulated by the ovaries is still a debatable question. Pflüger believes that the nervous system causes it; that the constant growing of the Graafian follicle causes a continued mechanical irritation of the nerves which are found in the stroma of the ovary and which, as late investigation has shown, surround the follicle with a fine network of fibrillæ. These irritations are conducted to the spinal cord and there accumulate; when they have reached a certain strength a reflex act takes place, which manifests itself in a congestion of the genitals. This brings about a bloody extravasation in the uterine mucosa with the ripening and bursting of the largest follicle. Others believe in chemical irritation produced by internal secretions,

which bring about these changes. These internal secretions of the ovaries enter the blood and there excite the vasomotor centers or ovarian nerves directly. Born and Frankel believe that not the entire ovary or its follicle, but only the corpus luteum, represents the gland (something that secretes), which by its internal secretions produces this cyclic monthly hyperemia which leads to menstruation. Frankel, during operations, destroyed these yellow bodies (lutea) by means of the cautery, and the menses at once stopped.

In reviewing five hundred histories of cases admitted into the Sydenham Hospital during a period of three years, it is interesting to note that the case to be reported is the only one of its kind that has occurred in that time. Ahlfeld reports a case of a woman who gave birth to numerous children and did not menstruate until her thirty-second year. Leviot reports a case of a woman who did not menstruate for fourteen years, and yet during that time became pregnant no less than four times. Gubler cites cases in which ovulation proceded menstruation by several years. A few cases are on record in which pregnancies have so rapidly occurred that menstruation had not appeared for years. Hirst reports a case of a woman 22 years of age, who had never menstruated and gave birth to a child, and another case where a woman menstruated only once after marriage and in the following fifteen years bore ten children without menstruating. Three years after the birth of the last child, or eighteen years since its cessation, menstruation returned copiously and was repeated more frequently than normal for twelve years. The menopause began in the forty-eighth year. In 1894 Leopold and Miranoff made an extended study of the conditions of ovaries removed at operations on forty-two women, whose menstrual history had been carefully noted. In thirty-two cases they found that menstruation and ovulation were synchronous, in eleven menstruation occurred without any trace of ovulation, while in one ovulation occurred in the middle of the intermenstrual period. A number of observers have attempted to show that menstruation may occur independently of ovulation, basing their contention upon the occasional continuance of menstruation after removal of the ovaries, but Gordon, Meredith, and others have demonstrated that after they had removed the ovaries ovulation took place and was either due to the presence of an accessory ovary or that a small part of the ovary was left, which has been shown to be sufficient for its occurrence. Waldeyer in 1873 first directed attention to the presence of accessory ovaries, which are sometimes found on the broad ligament in the region of the main ovary, resulting from faulty development or inflammatory changes occurring during fetal life, as a consequence of which small parts of the ovary have been cut off from the body of the organ.

The results following various operations on the genital tract show that menstruation is dependent on the presence of ovaries, but that ovulation may take place without the presence of the uterus, as it is generally conceded that complete removal of both ovaries, which necessarily stops ovulation, is always associated with cessation of the menses. On the other hand, total removal of the uterus, while associated with abolition of menstrual flow, exerts no effect upon ovulation, as is manifested by the regular occurrence of menstrual molimena. Clinical experience has shown that ovulation and subsequent pregnancies might take place without menstruation, as was demonstrated by the instances of conception occurring before the first menstrual period, and after the menopause, as well as during lactation, when the menstrual flow is usually absent. It is, therefore, evident that menstruation and ovulation occur about the same time, but that one not infrequently antedates the other by a few days, while in exceptional cases they may occur quite independently, but in any event are absolutely dependent upon the presence of ovaries. A common occurrence of ovulation without menstruation is impregnation during lactation. Remfry has found by investigation among nine hundred nursing women that in 57 per cent. only did there occur an absolute amenorrhea; menstruation was regular in 20 per cent., and irregular in 43 per cent. It was also common for conception to occur during lactation, 60 per cent. of menstruating women conceiving. Among the non-menstruating women, only 6 per cent. conceived during lactation.

The case that I desire to report was admitted to the wards of the hospital on February 9, 1911. She was a Russian Pole, primigravida, a well developed and husky girl of the blonde type, 20 years of age, not anemic, but intelligent and understanding English perfectly. All her measurements were normal and she was delivered of a normal child the same day. She had only menstruated once at the age of 17, for about three days, not profusely, but with cramp-like pains in the abdomen and back. Since that time she has never menstruated nor has she had any molimina during the expected period and she did not realize that she was pregnant even after the fourth month, when her abdomen was already slowly enlarging, for she came to the dispensary to inquire as to the cause of her condition. At the end of the tenth day she was discharged with instructions to report at frequent intervals for future observations.

The Hemolytic Streptococcus in Puerperal Infection.—M. Metzger states that we have not as yet found a diagnostic method to distinguish between virulent and non-virulent streptococci in the vaginal secretions and blood. Hemolysis was a short time ago considered an exact differential test, but since then it has been shown that non-hemolytic streptococci are found in severe cases, and also hemolytic streptococci in harmless discharges. It has been shown by some authors that the property of hemolysis was but temporary and due to virulence of the germs, and that the hemolytic can be transformed into non-hemolytic bacilli by passage through mice and other animals. The same results are obtained with the secretions of the vagina, uterus, and blood. The presence of streptococci in the blood is a bad prognostic factor. Hemolysis indicates that the blood is a good culture medium for the germs, and rather shows the resistance of the organism than the virulence of the microbe. Culture on blood-agar is a simple prognostic method, basing one's conclusions on the rapidity of hemolysis and the number of colonies found. Normal puerperal women may be carriers of streptococci that become virulent.—*La Presse Médicale.*

THE ASSOCIATION MEETING.

THE meeting of the American Medical Association, held the last week in June at Los Angeles, was one that will take its place among the memorable sessions of this body. The attendance was comparatively small, the registration numbering only about 2,200, but it was large considering the distance from the populous centers of the country, and the representation from the Eastern States was greater than had been anticipated. What the meeting lacked in numbers, however, it made up in enthusiasm. In spite of the powerful attractions of Los Angeles and its surroundings and the many temptations to neglect the scientific work, the attendance at the section meetings was remarkably good, and, as our special telegraphic reports last week and this bear evidence, a number of most interesting papers were presented and discussed. The welcome extended by the physicians of Los Angeles was extremely cordial. The entertainments provided for the visiting members were numerous and unique in character, and the work done by the Committee of Arrangements in providing convenient plans for registration and section meetings was most satisfactory.

A commendable feature was a series of health talks to lay audiences given in connection with the meeting by a number of prominent sanitarians and hygienists. The House of Delegates endorsed the Owen bill creating a Department of Public Health, at least, according to the wording of the resolution, it endorsed the "principle" of the bill. By this we understand that it favored the creation of such a department, without putting its stamp of approval upon all the details of the present bill. We cannot believe that the Association will meekly submit to the humiliation of seeing the Department of Public Health made inferior to all the other departments of the national government, with a layman at its head who is denied a seat in the President's Cabinet.

For the first time in many years a change has been made in the offices of the secretary and treasurer, Dr. Craig having been elected to the former position and Dr. Pusey to the latter. The unanimous election of Dr. Abraham Jacobi to the presidency of the Association will meet with the hearty approval of every physician of the country, whether a member of the Association or not, for, as we said a few weeks ago when the MEDICAL RECORD suggested his nomination, no one can be more deserving of this distinction. The American Medical Association has done honor to itself in thus honoring one of its oldest and most renowned members.

LIGHTS AND SHADOWS OF ENGLAND'S INSURANCE SCHEME.

FOLLOWING the enthusiasm with which the English public received the first announcement of the government's imposing scheme of national health insurance, there is a growing tendency, particularly in British medical circles, to look upon this measure not entirely as an unmixed blessing, and to advocate the exercise of extreme caution before it is enacted into law by the House of Commons. The fears that have been entertained by practically the entire British profession, that the contemplated law would not only fail to mitigate the evils of contract practice, but would magnify and extend these evils by giving national scope and governmental compulsion to a practice that is now purely local and voluntary, have apparently been justified by official statements as to the terms with which the government proposes to compensate physicians for their services under the new scheme. The hard-worked "lodge doctor" of American cities may feel exceptionally contented with his own lot when told that, according to the calculations of the Chancellor of the Exchequer, the proposed law would permit the average payment per annum of a capitation fee estimated at one dollar and a half for each person insured. This sum would include payment not only for medical attendance, but *also for the drugs, dressings, and appliances used in domiciliary treatment.* It is quite natural that the British profession would unite in emphatic protest against the consummation of a deal in which the practitioner will be, as he has been in the past, the inevitable loser. This protest has assumed the form of a memorial drawn up by the British Medical Association and addressed to the government and to members of Parliament. The chief demands are better payment for the practitioner attending beneficiaries under the proposed law; the restriction of medical benefits to those only whose income does not exceed $10 per week; the provision that the beneficiaries shall have free choice of doctor from among those practising in the district who are willing to enter into arrangements under the bill; and that the administration of the medical and other benefits shall be in the hands of local health committees and not of the friendly societies.

Although there are certain features of the new scheme that will appeal to both the public and the profession, these advantages will not close the eyes of the profession to many of the drawbacks associated with the nationalization of contract practice. For certain practitioners who have not been able to make both ends meet enlistment in the service of the government will guarantee a definite income, but if only the least fit in the profession are attracted by the prospect of increasing their earnings, the public will not receive the best form of medical attendance. Those who are enjoying the fruits of a remunerative private practice will hardly care to exchange these for the drudgery of public service. A third class of prac-

titioners will be compelled to accept this kind of work. They are the large body of earnest and hard-working men whose practice has been built up among people of moderate incomes. The proposed law would bring all of the latter within its scope, with the result that their former medical attendant would have nothing to do unless he enlisted in the service of the government. The result of the latter alternative would be that in order to maintain his former income the practitioner would be compelled to work all the harder, in view of the larger number of patients that he must necessarily attend. The hardships would be keenest in the case of the older physicians and those practising in rural communities.

As against these glaring disadvantages that will undoubtedly affect a large number of British practitioners, it may be noted that the abuse of hospitals and dispensaries will be greatly diminished by the fact that those who in the past have sought gratuitous medical service will in the future contribute to the fund that will compensate the practitioner for services that he has supinely granted for naught but the satisfaction of helping his fellow man. But this satisfaction did not help to fill the mouths of the hungry, nor did it enable the physician to set aside a competence for his old age, and for his family when he died. No one has ever been able to gauge the vast monetary value of the services which the medical profession has gratuitously donated to the State. The injustice of this has been emphasized time and again.

It is gratifying to note that the example of American life insurance companies in the inauguration of welfare work—by the dissemination of literature upon personal hygiene, by furnishing medical advice to their policyholders, by supplying district nurses, and finally by establishing sanatoria for the benefit of those of their policyholders who may contract tuberculosis—that this example has been followed in the English scheme of national insurance, with its princely appropriations for the construction of sanatoria and for their maintenance. The most extravagant dreams of the socialist could not conjure up a more fatherly attitude of the State toward its numerous offspring. But this attitude is not one of purely disinterested altruism. The Englishman by tradition is a shrewd economist. Does he not perceive with a vision that is not restricted to the present generation, but gazes far into the future, that whatever governmental outlay will aid in alleviating the burdens of the population will tend to produce a healthier and more sturdy race and will eventually diminish the nation's expenditures for the care of the sick, the insane, the paupers, and the criminals? The enlightened statesman of to-day recognizes the fact that health is one of the national assets, and must be safeguarded with greater zeal than other resources.

The experience of Germany has demonstrated that national health insurance is not a visionary scheme concocted in the brain of parlor statesmen. But legislation designed to improve the public health need not be enacted at the price of injustice to the medical profession.

THE BEGINNINGS OF MIND IN THE NEWBORN.

Notwithstanding the interest in this subject from the standpoint of neurology and pure psychology, comparatively few collected observations based on a large series of cases have been published. The first scientific observations in this field seem to have been made late in the eighteenth century by Tiedemann, and since his time a great number of excellent biographical studies of single infants have been recorded. Up to the time of the publication of Sigismund's interesting work, entitled "Kind und Welt" (1856), there was much confusion and misinformation in regard to the order of the appearance of the various senses in newborn children. The first collective investigation into the mental life of newborn children in a maternity hospital was made by Kussmaul in 1859, and subsequently these studies were repeated under similar auspices by Genzmer in 1873, and by Kroner in 1882. None of these observations was carried out, however, on a series of more than fifty children. A more recent and much more extensive investigation has recently been carried out by Frederick Peterson on a series of 1060 individual babies in the wards of the New York Lying-In Hospital. The interesting results of this investigation are reported in the *Bulletin of the Lying-In Hospital*, Vol. 7, No. 3. A series of tests were devised to determine the first appearance of the various senses and sensations and the material observed was carefully classified as regards the age and maturity of the infants and according to certain extraneous circumstances. The conclusions arrived at by Peterson are rather interesting although they are presented as being incomplete and subject to further elaboration.

Sensibility to light seems to be present in most infants at birth, and this is the case even in those prematurely born. The optic nerve is even prepared to receive impressions some time before birth at full term. Sensibility to sound was found to be quite as apparent as sensibility to light at birth, for 276 normal white children reacted to sound on the first day of life, and 146 reacted to light. A similar condition existed among the premature infants, many reacting to sound on the first day as well as to light. The auditory nerve is, therefore, likewise prepared to receive impressions of sound before the period of normal birth. This seems wholly contrary to the opinion of other authorities. The gustatory nerve was found to react differently to salt, sweet, bitter and sour substances at birth, and the same mimetic reactions were also observed in premature infants. The olfactory nerve was observed to receive impressions in newborn children at term, and likewise in premature infants. Reactions to touch, temperature, or other painful stimuli were present in normal as well as premature infants, but Peterson believes that sensitiveness to painful stimuli although present is more vague and uncertain than in later life, which leads many to assume that the sense of pain is dulled in the newborn. An interesting fact was also observed as regards the sensations of thirst and hunger, which were frequently noted on the first day

although the actual need of food was sometimes apparent only after the first or second day. Discomfort seemed to be clearly marked when nourishment was not forthcoming even in some of the premature infants.

There seems to be good ground for believing that the newborn child comes into the world with a small store of experiences and associated feelings and shadowy consciousness. The fact that even in premature infants the senses are found to be prepared for the reception of impressions is believed by Peterson to constitute evidence that such impressions have been already received and stored in the dim storehouse of a memory already begun. He even goes so far as to say that possibly some sort of vague light impressions have been received, on the supposition that in the interior of the body alternations of day and night may in a mild degree be manifested. He bases this supposition on the transillumination of the hands by a candle and of the frontal sinuses and antrum by the electric light, claiming that sunlight will attain an even greater penetration than any artificial light. He believes that there is even a greater possibility in the stimulation of the auditory sense by sounds produced within the body of the mother, possibly through the medium of bone conduction. The stimulation of the gustatory nerve is thought to occur through the frequent swallowing of amniotic fluid by the fetus. To show that infants start out in life on a common plane, a comparison was made in the reactions of colored and white children, and no perceptible differences were obtained.

By way of comment on these interesting observations, it might be stated that their publication will do much to overcome the feeling rather too prevalent among the laity as well as physicians, that the newborn are not sufficiently endowed with the various sensations to appreciate the ordinary stimuli, whether these are painful or pleasant. Although observations of the kind referred to are necessarily both difficult and uncertain, yet when systematically carried out on such a large number of infants the possibility of error is eliminated to a large degree. It is to be hoped that further research along these lines will be developed.

ANNUITY INSURANCE FOR PHYSICIANS.

The importance of physicians making some provision for a definite and certain income in their old age is discussed in an able editorial article in the *Old Dominion Journal of Medicine and Surgery*, May, 1911. It is not uncommon to behold physicians, particularly in the rural districts, who, with advancing years, cannot compete with their younger colleagues, and who find their former lucrative practice and comfortable income gradually slipping away. This is all the more distressing in view of the fact that the practitioner in his days of prosperity was compelled, both for social and business reasons, to live up to his income. The vanishing practice, whether the result of the keen competition of the younger men or the unfortunate outcome of the infirmities that come with advancing years, can no longer maintain the high standard of living to which the practitioner has been accustomed. He has been able to save little or nothing, and in many instances he is compelled even to allow his life insurance policy to lapse.

Is this plight of the older men in the ranks the result of improvidence in their days of plenty? To a certain extent it is, for no physician dependent upon his brains and physical well-being for a livelihood can afford to ignore the necessity of insuring at any rate a part of his income. College professors, officers in the army and navy, and even members of various labor organizations may look forward to an annuity during their years of retirement, but the doctor who has not inherited or wedded a fortune, or who has not acquired wealth as the result of extraordinary ability in the practice of his calling, or of happy speculation, in most cases can not look forward to a certain income in the unproductive years of his life.

A plea is made that the physicians of this country, through their influential organizations, should establish a system of voluntary annuity insurance, with benefits accruing at a certain age limit, as sixty years. The beneficiaries, having contributed the regular annual premiums, would at that age begin to receive the annuity. It is suggested that a physicians' annuity company, run with a minimum office expenditure, could carry on this work to better advantage than the regular insurance companies. Without attempting to admit the validity of this belief, there can be no doubt that the members of the profession, either on their own initiative, utilizing their own organizations, or availing themselves of the forms of annuity insurance obtainable through the ordinary channels, should seriously consider the necessity of insuring their own earning capacity, for annuity insurance is equivalent to this.

The Peristaltic Hormone.

The so-called hormone which has given the greatest promise as a therapeutic agent is that which preexists in the gastric mucosa (the gastrin of Edkins), the spleen, and elsewhere. The fact that it occurs in abundance in the spleen, unassociated with such pathogenic spores as might possibly find themselves in the stomach, led Zuelzer to obtain the body from that gland; for the hormone can be used only by intravenous injection, and cannot be sterilized by heat sufficient to destroy spores without affecting its integrity. At the recent meeting of the German Surgical Society Henle reported on the use of the peristaltic hormone in postoperative intestinal paresis (*Deutsche medizinische Wochenschrift*, May 18). In five severe cases the remedial action was thoroughly in evidence. All synergistic remedies and procedures should be combined with the injections, and the latter may be repeated if necessary, although a well-marked febrile reaction sometimes follows the use of the remedy. The peristalsis obtained is not so striking in the clinic as in animal experiment. Dencks has used the hormone freely both experimentally and in the clinic. The remedy he finds deposited in the spleen, its original source. Peristalsis develops in from ten to fifteen minutes. The action may be permanent, persisting for months. If the subject is greatly

constipated no immediate effects may be noted, and peristalsis may set in only after several days' interval. Results in intestinal paresis are inconclusive. The speaker observed a rise of temperature, but no other collateral phenomena. Borchardt recommends the hormone in the intestinal inactivity of spinal disease. In postoperative paresis he has seen both brilliant results and failures. Zuelzer, the discoverer of the splenic hormone, now uses it to differentiate between chronic constipation and ileus. In 25 cases of postoperative paresis Goldmann saw 10 prompt results and 5 total failures.

Blood Culture in Infectious Diseases.

Any one who has had much experience in bacteriological work has often obtained sterile blood cultures from patients obviously suffering with some form of bacteriemia. N. Klodnitzky (*Centralblatt für Bakterienkunde, etc.*, Vol. 58 No. 4) thinks that this is due not only to the bactericidal activity of the serum and the phagocytic powers of the white cells, but also to the red cells, which carry an easily available store of oxygen. In order to avoid these effects, various investigators have employed several methods, such as the marked dilution of the blood, an immobilization of it in agar, or the use of some medium containing a hemolytic agent. The author considers the bile salts the best of the hemolytic agents when attempting to isolate the typhoid bacillus, but they hinder the growth of many other organisms. His method is to obtain 0.5 to 1.0 c.c. of blood, with a syringe, from a superficial vein of the arm and to mix this with 4 or 5 c.c. of sterile distilled water. This procedure causes hemolysis of the red cells and destroys or dilutes the protective agents. The solution can then be used for the preparation of smear or hanging-drop, and from it cultures may be made on any media desired. He condemns the puncture of organs such as the liver or spleen. He considers the post-mortem blood culture of great value. The protective substances usually disappear shortly before death and it is said that the blood in the median basilic vein remains uncontaminated for a long time thereafter. For these reasons a blood culture taken at autopsy will frequently give bacteriological information unobtainable during life.

Phosphorus and Lecithin in the Treatment of Migraine.

The introduction of lecithin into therapy appears to have given a certain impetus to a revived exhibition of phosphorus as a so-called tissue remedy. At a recent meeting of the Gesellschaft für Natur und Heilkunde zu Dresden (*Münchener medizinische Wochenschrift*, May 23), Schottin expressed the belief, founded on ten years' study, that migraine is due to poverty of the cortical centers in phosphorus. The supervention of attacks while the mind is active, the disappearance of attacks during sleep, the stimulation with consecutive paresis of the optic and acoustic nerves (this constituting an aura), with similar involvement of the arm center, all point to a cortical location. The headache is attributed by Schottin to increased sensitiveness of the cortical sensory centers, which is propagated from the cortex to the vomiting center. The author treats migraine, *i. e.* the tendency to the paroxysms, with a nontoxic combination of phosphorus and lecithin in oil. The favorable results claimed seem to be the principal reason for the belief in the phosphorus-starvation theory of the origin of this neurosis. The author expresses a belief that spasmophilia in children has an analogous origin and upon similar grounds, viz., improvement under the use of phosphorus.

Has the Spirochete a Resistant Stage?

A very interesting observation has been made by Andrew Balfour (*Journal of Tropical Medicine and Hygiene*, Vol. XIV, No. 8) in his study of the spirochetosis of Sudanese fowls. He gave a chick, infected with this disease, a large dose of salvarsan and shortly afterward punctured the liver. Examination of this pulp with the dark-ground illumination revealed swarms of spirochetes, some of which could be seen to discharge highly refracting spherical granules and soon afterward die. This same process may also take place in the circulating blood. These granules enter the red cells and, according to Balfour, are identical with the granules of Leishmann, and possibly with the so-called "coccoid bodies" seen in the blood in human relapsing fever. He has found them to be resistant forms and thinks their presence may be sufficient to explain the difficulty of curing completely chronic spirochetal infections as syphilis and yaws.

News of the Week.

American Medical Editors' Associaton.—The forty-second annual meeting of this association was held at the Hotel Alexandria, Los Angeles, on June 26 and 27, under the presidency of Dr. Joseph MacDonald, Jr. Papers were read as follows: "Physical Therapeutics in the Medical Press," by Dr. Arnold Snow; "What Shall We Publish?" by Dr. J. R. Phelan; "The Extension of Advertising in Medical Journals," by Mr. S. DeWitt Clough (by invitation); "The Influence of Medical Journalism for Medical Progress," by Dr. W. Benham Snow; "The Literary Side of Medical Journalism," by Dr. T. D. Crothers; "A Plea for Scientific Classification of Disease," by Dr. Winslow Anderson; "The Future of American Medical Journalism, Once More an Optimistic Outlook," by Dr William J. Robinson. A number of papers were read by title, the authors not being present. The following officers were elected: *President*, Dr. Walter Wyman, Surgeon-General U. S. Public Health and Marine-Hospital Service; *First Vice-president*, Dr. Thomas L. Stedman, New York; *Second Vice-president*, Dr. Walter Lindley, Los Angeles; *Secretary and Treasurer*, Dr. Joseph MacDonald, Jr., New York; *Executive Committee*, Drs. W. C. Abbott, Chicago; C. L. Stevens, Athens, Pa.; G. H. Kreidler, Cincinnati. The annual banquet was held on the evening of June 26 in the Hotel Alexandria. The members and guests, the latter including many ladies, numbered eighty-five. Dr. MacDonald, the president of the association, was toastmaster. The following were the speakers: Dr. Wm. H. Welsh, president of the American Medical Association; Col. Wm. C. Gorgas, Dr. Walter Lindley of Los Angeles, Hon. James Slauson, President of the Los Angeles Chamber of Commerce; Rev. F. W. Clampitt of San Francisco, Dr. Winslow Anderson of San Francisco, and Dr. Wallace C. Abbott, of Chicago.

The Association of American Teachers of Children's Diseases met in the Barlow Medical Library, Los Angeles, on June 26, under the presidency of

Dr. W. C. Hollopeter of Philadelphia. An address on "The Baby Tent" was delivered by Dr. F. W. Allin of Chicago, and a paper on "The Aims and Purposes of Our Association" was read by Dr. A. C. Cotton of Chicago. Dr. W. C. Hollopeter of Philadelphia, president of the association, delivered a brief address in which he spoke of the work of the organization since its inception five years ago. The following officers were reelected: *President*, Dr. William C. Hollopeter of Philadelphia; *Vice-president*, Dr. John Zahorsky of St. Louis; *Secretary*, Dr. J. Ross Snyder of Birmingham, Ala.; *Treasurer*, Dr. George H. Cattermole of Boulder, Col.

Prizes of the American Medical Association.—The following awards were made by the committee in the scientific exhibit of the American Medical Association at the Los Angeles meeting:

(A) For the best research exhibit: (1) Gold medal awarded to the exhibit of the United States Public Health and Marine-Hospital Service for its exhibit of preparations and material concerned with research in plague and leprosy. (2) Certificate of Honor for research exhibit on investigation of pernicious malarial infection with reference to malarial hemolysins, awarded to Dr. Walter V. Brem, Colon Hospital, Cristobal, Canal Zone. (3) Certificate of Honor for research exhibit on nephritis, awarded to Drs. William Ophuls and Ernest C. Dickson, Cooper Medical College, Leland Stanford University. (4) Certificate of Honor for research exhibit on classification and identification of the parasites of the order of Trematoda, awarded to Drs. Henry B. Ward and E. F. Hirsch, Zoological Department, University of Illinois.

(B) For the best general exhibit: (1) Gold medal awarded to Pathological Exhibit of Hendryx Laboratory of the Los Angeles Medical Department, University of California. (2) Certificate of Honor awarded to Cooper Medical College, Leland Stanford University.

Civil Service Examination.—The New York State Civil Service Commission announces an examination to be held on August 5 for the purpose of filling vacancies in the position of prison physician at a salary of $2,000 a year. Full particulars can be obtained from the State Civil Service Commission, Albany, N. Y.

Civil Service in Illinois under the recently enacted law, has been extended so as to embrace the State Board of Health, the officers and employees of which are given fixed tenures of office regardless of change of politics. All persons who held offices or places on July 1st became members of the classified service without examination. This made Dr. James A. Egan the permanent Secretary.

Infant Mortality.—Commissioner Lederle announces that during the week ending June 24 there were 61 deaths from diarrheal diseases among children under five years of age in New York, a striking decrease as compared with the figures for the corresponding week of 1910 when there were 136 deaths from the same cause.

Federal Aid Asked.—The Harvard University Research Laboratories at Shanghai, China, having received a joint appropriation from the Legislatures of the Pacific Coast States and Hawaii for the study of Oriental diseases, have asked that Dr. George W. McCoy of the Public Health and Marine-Hospital Service be sent to Shanghai to cooperate with the laboratories in endeavoring to prevent the spread of these diseases to the United States.

Quarantine on Dogs.—The State Board of Health of Kansas has ordered a State-wide quarantine on dogs for ninety days, because of the prevalence of rabies.

In New Rochelle, N. Y., the quarantine against dogs which had been in force for eight months was removed on June 30 by order of the State Commissioner of Agriculture.

Railroad Hospital Department.—The employees and officers of the Illinois Central Railroad recently voted to establish a hospital department to be maintained by a contribution of 50 cents a month from all employees. In return for this the men will receive in times of sickness hospital treatment at designated hospitals, or treatment at home or at the offices of the department surgeons, medicines, and surgical dressings, artificial limbs and eyes, surgical appliances, and spectacles required as the result of an injury. In the case of the death of a contributor an allowance for burial will be made.

The Institutional Census.—One of the details of the recent census was the enumeration of persons in institutions of various sorts. The preliminary report which has just been made shows a striking increase in the number of insane in institutions. In 1904 there were 150,151 such persons, while in 1910 they had increased to 184,123, or 22.6 per cent. During the year 1904 the number of commitments to insane asylums was 49,622, and during 1910, 59,628, an increase of 20.2 per cent. In 1904 the feeble-minded in institutions numbered 14,347 and in 1910, 20,199.

Rockefeller Institute.—The Board of Scientific Directors of the Rockefeller Institute for Medical Research announce the following appointments to the staff of the institute: Alfred E. Cohn, M.D., Associate in Medicine; Arthur W. M. Ellis, M.D., and Alphonse R. Dochez, M.D., Assistant Resident Physicians; Frank W. Bancroft, Ph.D., Associate in Experimental Biology; Reinhard H. Beutner, Ing.D., Assistant in Experimental Biology; James B. Murphy, M.D., Assistant in Pathology; J. J. Bronfenbrenner, Fellow in Pathology; Frederick B. LaForge, Ph.D., and Angelia M. Courtney, Assistants in Chemistry; Henry K. Marks, M.D., Assistant in Pathology, and Helen L. Fales, Research Scholar in Chemistry.

Honorary Degrees.—Dr. William Bradley Coley of New York, professor of clinical surgery in the Cornell University Medical College and director of the Huntington Fund for Cancer Research, received the honorary degree of Master of Arts at the commencement exercises on June 28.

Surgeon-General Walter Wyman of the United States Public Health and Marine Hospital Service received the honorary degree of Doctor of Laws from Amherst College on June 28. In bestowing the degree President Harris of the college said: "He renders a service to humanity than which none could be greater."

Dr. G. G. Davis, professor of orthopedic surgery in the Medical Department of the University of Pennsylvania, Philadelphia, has received the honorary degree of Doctor of Laws from Lafayette University.

The University of Michigan, in recognition of the advance of preventive medicine, recently created the honorary degree of Doctor of Public Health, and at the commencement exercises on June 29 this was bestowed on Dr. William A. Evans, professor of hygiene and sanitary science in the Northwestern

University Medical School, and for many years connected with the Department of Health of Chicago, and on Dr. Guy L. Kiefer of the Department of Public Health of Detroit.

New Immigrant Hospital.—The new hospital at Ellis Island, New York, for the treatment of contagious diseases among the immigrants, was opened on June 22, 1911. The new structure provides for the complete isolation and treatment of measles, scarlet fever, diphtheria, and any other contagious disease which the Health Officer of the Port will allow past the State Quarantine. The wards intended for patients with measles contain 480 beds and cribs. The six detached wards have a capacity of twelve patients each. The opening of the hospital will abolish a long-standing inconvenience. Heretofore cases of contagious disease occurring among the immigrant children have been taken care of under contract with the Government in institutions in New York or New Jersey, or else it has been necessary to return the patients to the State quarantine hospitals on Hoffman and Swinburne Islands.

Obituary Notes.—Dr. Julian William Baird of Boston, Mass., a graduate of the University of Michigan in 1882, and of the Harvard University Medical School in 1890, professor of analytical and organic chemistry in the Massachusetts College of Pharmacy, Boston, since 1886, and Dean of the College since 1897, and a member of many chemical societies, died at his home on June 26, aged 52 years.

Dr. John Franklin Whitmyer of New York, a graduate of the College of Physicians and Surgeons, New York, in 1890, a member of the New York State and County Medical Societies, and chief medical inspector in the Department of Health of New York, with which he had been connected for over twenty years, died suddenly of heart disease at his home on June 23, aged 47 years.

Dr. Daniel F. Summey of Leicester, N. C., a graduate of the Medical Department of New York University in 1860, died at his home on June 13, aged 80 years.

Dr. Charles Ott of Kansas City, Kan., a graduate of the Ensworth Hospital Medical College of St. Joseph, Mo., in 1895, a member of the Missouri State and Wyandotte County Medical Societies, professor of the practice of medicine in the Kansas City Hahnemann Medical College, and a member of the attending staff of the Kansas City General Hospital, died in Higginsville, Mo., on June 9, aged 60 years.

Dr. Charles H. Holmes of Millen, Ga., a graduate of the Medical Department of the University of Georgia in 1901, died at his home on June 12, after a short illness.

Dr. Irving W. Johnson of Peoria, Ill., a graduate of the Hahnemann Medical College of Philadelphia in 1856, died at his home on June 12, aged 79 years.

Dr. Harvey A. Warner of Topeka, Kan., a graduate of the Medical Department of the University of Wooster, Cleveland, Ohio, in 1873, a member of the American Medical Association, the Kansas State and Shawnee County Medical Societies, and the Topeka Academy of Medicine and Surgery, lecturer on life insurance in the Kansas Medical College, and well known in fraternal life insurance work, died at his home of apoplexy on June 9, aged 61 years.

Correspondence.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

POLLING THE PROFESSION ON THE INSURANCE BILL —PLAGUE-INFECTED RATS IN EAST LONDON— HARVEIAN ORATION—ROTUNDA HOSPITAL REPORT —DR. NEVE'S EXPLORATION OF THE HIMALAYAS.

London, June 16, 1911.

Objections to various parts of the State Insurance scheme are growing apace. The Friendly Societies are expressing dissatisfaction with the assurances they have received and are much concerned about their reserve funds. Some Chambers of Commerce are formulating objections to the high wage limit and to compelling employers to pay for their workmen over the insurable age. Householders are saying they ought not to pay for domestic servants. Hospital managers are afraid of losing a great percentage of their subscriptions. The medical profession has made a demonstration which has surprised the Government as well as the Friendly Societies. Mr. Lloyd George has been to Birmingham and there made a speech which has not tended to give confidence to any of the objectors. He appeared to make some concessions, but when the phrases were analyzed they seemed quite capable of being repudiated, besides which he said he spoke on certain points for himself, but they must come before Parliament. Thus he may very well state his personal opinion and afterward can plead he is overruled by his colleagues or by the House. He proposed to favor the demand for the free choice of the doctor by each injured person, and even said that would rather prevent malingering which would cause unfair distribution in the list or panel of medical men. He promised adequate representation of the doctors on the Health Advisory and Insurance Committees, and admitted that there might be just claims for extra services. But he adhered to his wage limit, although that has been generally declared as unreasonable.

The British Medical Association has been taking a poll of the profession, and to-day it is stated at their office that 15,000 reply cards have arrived supporting the demand formulated at the mass meeting reported in my last. Of course, adhesion to the policy commits no one to more than an opinion. But the number ought to warn Mr. Lloyd George that all his plausibility cannot cajole a whole profession, which, if determined, can render his measure futile, so far as sick insurance is concerned.

The *Practitioner* announced that its conductors would go to the expense of a referendum of the profession, and one was ready for issue on somewhat broader lines than the poll of the association when the latter urged the importance of an absolutely united front being presented to the Government. The *Practitioner* has, therefore, postponed its referendum in order to show there is no division in the profession. It is an example to be commended in view of the fact that on most previous occasions divided forces have led to defeat of professional claims.

It is to be regretted that the association, with its usual trade instincts, is making its poll also a canvass in its own interests, urging every medical man to become a member and so subscribe to its journal.

Some plague-infected rats have been found on a riverside wharf in East London. The owner in-

formed the medical health officer that six dead ones had been found and three of them were immediately sent to the Government Board bacteriologist. Two were found to have died from pneumonic plague. Six others were found on Tuesday and three had died from pneumonic and one from bubonic plague. Every precaution is being taken to prevent the spread of the infection. The practitioners of the district are asked to report any suspicious case of pneumonia to the medical health officer. Notices have been posted in the wharves and other places pressing the work people not to handle any dead rats but to put them in water by tongs or other instrument. It is also urged that rats be not poisoned but trapped. The sanitary staff of the Borough Council is doing all it can to avert the danger, including house-to-house visitation. Whence the infected rats came has not been discovered. No ship from an infected area has arrived at the wharf where they were found for many months.

Dr. J. H. Sequeira, dermatologist to the London Hospital, gave the annual oration at the Harveian Society, devoting it to the progress in his specialty since Hunter's time. He selected several interesting observations of John Hunter referring to the skin. One of the first was as to humors afloat in the blood. "If I have a faint idea of the meaning of this expression," wrote Hunter, "it describes something extraneous or foreign, something that does not belong to the blood itself"—an idea, said the orator, identical with our notions of toxemia. Hunter remarked that it would be a good thing to ascertain what sores should be dressed and what should not, and added "all cutaneous sores do best without dressing; excoriations and pimples had best be left to themselves." Dr. Sequeira remarked on this that in those days there was trouble from overtreatment and cited the well-known case of spreading pimples on the leg and Hunter's conversation with the patient. To "what was to be done" he said "nothing." To "how so," he said, "can anything be easier." To "the stocking will then stick to it," he answered "let no stocking be worn, put the boy in trousers." The advice was followed and the leg healed rapidly. In Hunter's days large doses were the rule, as might be expected, for hard living, hard drinking, and hard swearing were characteristic of the era. It was interesting, now that tropical diseases occupy so much attention, to find that Hunter was familiar with a number of them. The orator then sketched briefly the development of our knowledge of skin diseases, speaking of three epochs: the first that of describing the objective phenomena, the second when the study of histology flourished, the third when it was proved that many diseases are caused by microparasites. Then followed observations on eczema, parasitic diseases, tuberculosis, leprosy, etc. But space is limited. I pass them by for the remarks on therapeutics, which our readers may be more interested in on account of Dr. Sequeira's long experience in the enormous field afforded by the London Hospital. Internal treatment, he said, naturally held sway when skin diseases were thought to be due to morbid humors circulating in the blood. Of late years there had been a reversion to that view, though on different lines. Toxins might be brought in from without or developed within the body. Recognizing they could come from outside led to the discovery of parasites and the local use of parasiticides. Impetigo, caused by coccal organisms, was rapidly cured by antiparasitic applications. Seborrhoides were influenced by sulphur, long known empirically, now established as a rational remedy. As to tuberculin, Wright had shown its effects could be graduated by observing the opsonic index and the risks run in earlier use could thus be avoided. Analogous to that was vaccine therapy. We had been provided by bacteriologists with numerous preparations. Our results had not been uniform. Occasionally in furunculosis rapid disappearance had followed a staphylococcal vaccine. In other cases, including staphylococcal acne, results had been disappointing. The inoculation treatment of acne vulgaris with vaccines from the acne bacillus had also failed, and it seemed likely that the cause of this common disease was yet to be discovered. Most striking was the use of physical agents in the last twelve years—heat, cold, electricity, ionization, *r*-rays, radium. Instruments of precision enabled us to fix dosage and thereby avoid the dangers at first met with. It was once common for a child to be treated for a year or two for ringworm. Nowadays it could be cured in a couple of months. Rodent ulcers were now cured in a way that was spoken of as "miraculous." (This adjective is too often used—would not marvelous, or wonderful, do as well?) Extreme cold was the last remedy considered, and the orator found it, for nevi of moderate size, patches of lupus erythematosus, and other cutaneous conditions, better than anything else.

The report of the Rotunda Hospital (1909-10) was read at the Dublin Academy by Dr. Hastings Tweedy. The president (Dr. H. Jellett) confessed that the results were surprisingly good, considering the conditions. A thousand more patients a year were being passed through the wards than they were built for. The teaching capacity, too, was thereby limited and to keep the morbidity at the lowest, examinations by students must be restricted. This might be bad for students after they became practitioners. Dr. Tweedy replied that when he took up the office of Master he felt the Rotunda would be doomed whenever architecture became the first consideration in maternity practice, for they could never compete in structure with some of the plans supported by Government money. But men were taught in the Rotunda what was needed for general practice, and the worst way would be to impress them with the importance of bricks and mortar. He thought examinations were made with the utmost safety, provided sterilized finger-stalls were always employed. Their nurses had too short training for private practice, as they left the Rotunda in six months; at the end of six years a large number of them were useless. To say that they should not decrease hospital morbidity at the expense of students' educational facilities was to argue against most, if not all, humanitarian procedure.

Dr. Arthur Neve gave an account on Monday at the Royal Geographical Society of some explorations in the Himalayas; he dealt with the effect on the mountains and valleys of aerial, aqueous, and glacial denudation, the exceptional force of earthquakes, landslides, glacial cataclysms and torrential rains. Lord Curzon, presiding, said Dr Neve was honored in Kashmir, for no Englishman had rendered such service to the people. He went out long ago as a medical missionary and so devoted himself to the welfare of the people that it had been a happy moment, one of his happiest

reminiscences, when Queen Victoria founded her new Order, and being asked to make eminations, he had selected Dr. Neve for one of the first recipients. It was in the intervals of his great work in Kashmir that Dr. Neve had explored the Himalayas. Sir W. Lawrence, Dr. Stein, Dr. Sven Hedin and Sir T. Holdich added their tribute to the great work done by Dr. Neve and other missionaries in exploring various countries.

OUR LETTER FROM PARIS.

(From Our Special Correspondent.)

THE REACTION OF WASSERMANN IN THE DIAGNOSIS OF LATENT SYPHILIS—TREATMENT OF OBESITY—TREPHINING AND DECOMPRESSION.

PARIS, May 15, 1911.

LETULLE has employed the reaction of Wassermann as a means of clinical diagnosis in a large number of patients. He has thus detected in a certain number of chronic maladies the presence of latent syphilis. In ninety chronic cases he got positive results in thirty-nine, a proportion of 43 per cent. Without the Wassermann reaction we should not be able to detect syphilis in a large number of hemiplegics, tabetics, and cancers. To sum up, the Wassermann reaction, when it is positive, has great value. Although, it is just to add, the serodiagnosis of syphilis aids us in discovering the disease when it is positive, it does not with certainty always enable us to discover it and to specify it surely. From the observations of Letulle we find that the spirochete is very frequent as the pathogenic agent of a crowd of infections of a chronic nature, more or less curable, and that the examinations made by the Wassermann reaction contribute to place syphilis in the front rank of social diseases, even before alcoholism or tuberculosis.

Maurice Fleury demonstrated the undesirability in the case of reducing flesh of allowing the denutrition to become too intense, for the result of such treatment may be to awaken a latent tuberculosis. We should not reduce the flesh of obese persons until we have made a serious inquiry into their past, and a careful and repeated auscultation. The reducing treatment should be watched over closely and carried out in a slowly progressive fashion. Two results are to be feared in reducing flesh: On one hand, the rapid return of the flesh, for many fleshy persons grow thin for but a few weeks, or the revelation of a latent tuberculosis. Rather than to simply reduce the obese, it is better to increase their nutrition permanently, and recreate their nervous energy, habitually asthenic. Injections of serum and the employment of extracts of the thyroid gland may be excellent adjuvants to the treatment. In the beginning, to free the organism from poisons, it is well to give a milk diet for three days and then begin the regular régime. The regulation of drinking is of great importance; pure water should be ingested in large amount, but only when the stomach is empty. By drinking abundantly at meals the gastric juice is diluted and its digestive value impaired. Foods which create adipose tissue should be cut off. At the same time the diet must be so varied that disgust does not result, and full enough that the patient may not be injured by the attempt. Lastly, it is necessary to advise muscular exercise; an hour and a half of walking daily in three instalments. This régime will be amply sufficient to sustain life; it is neither physically nor morally depressing, but favors muscular development.

Maurice Auvray has made an interesting study of decompressive trephining for brain tumors. It is generally admitted that decompressive craniectomy presents undoubted advantages in relieving patients suffering from cerebral tumors. This operation produces a reduction or even disappearance of the functional troubles which are caused by intracranial pressure. Decompressive trephining should be a part of the treatment of inoperable tumors of the brain just as gastrotomy is used in cancer of the esophagus. The good effects of cerebral decompression are not confined to cerebral tumor alone, but are of value in other cerebral conditions. Broca thinks that trephining is an excellent and often the only method to employ. It is often impossible to diagnosticate the nature of a cerebral tumor so that craniectomy may be the first and sometimes the only operation possible. Lucas-Championnière believes that decompressive trephining does not form a serious operation, but it is necessary to make very large openings, for economical operations often cause serious accidents. As to the technique of decompressive trephining, it is necessary and indispensable to open the dura mater; it is necessary even to open the meninges down to the cerebral surface. When the dura mater has been incised it is useless to suture it. Pierre Delbet thinks that decompressive trephining is an excellent method. Certainly this operation is only palliative and its effects do not last long, but it is nevertheless true that the advantage for the patient is very great. There are two reasons which recommend decompressive trephining; the possible retrocession of the optic neuritis, and the relief of the pains, which is immediate. These pains are atrocious and constitute a formidable punishment. Immediately after the operation the patient is transformed and expresses his satisfaction and thankfulness. If this does not prolong their existence it permits them to finish it under acceptable conditions, which is considerable. To sum up, we should not hesitate to do decompressive trephining. Segond thinks that a cerebral tumor should be extirpated only when its location is absolutely determined and its total removal is possible without excessive laceration. In all other cases of intracranial hyperdistention we should be content with palliative treatment; we should open the osseous cranium without incising the dura mater and by sacrificing the bone. Practised in this way decompressive trephining is surely a benign operation. Walter thinks that the diagnosis of the location of cerebral lesions is, in spite of everything, often impossible.

From the point of view of the technique of the operation, Walter uses only the gouge forceps and the ordinary trephine or rasp. He does the operation of removal of tumors in two sittings. Auvray summed up the discussion by showing the undeniable therapeutic value of decompressive trephining. Of course, we have to do with a simply palliative operation, whose benefit is felt for but a few months. But, after all, is not this the result of all palliative operations? We should not refuse to patients with cerebral tumors the benefit of an operation which permits them to finish their existence under acceptable conditions.

Influenzal Urethrocystitis.—Ghedini reports a case of this condition, and notes that Comby in 1894 made the first report of a similar condition. He has collected all the cases that have been reported in the French and Italian literature.—*Gazetta degli Ospedali.*

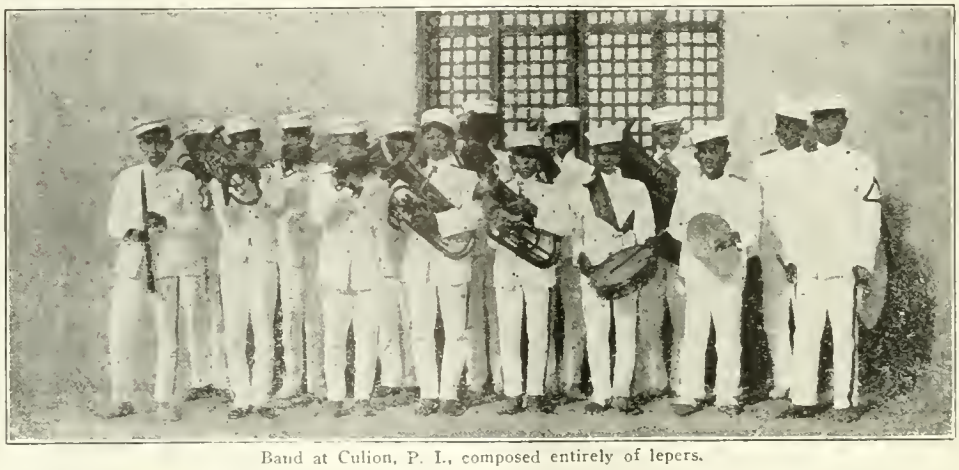
THE BAND AT THE CULION LEPER COLONY.

To the Editor of the Medical Record:

Sir:—I am forwarding herewith a photograph of an organization which is unique in musical and medical annals. It represents the band at the Culion Leper Colony, Culion, P. I. At the present time there are approximately 2,200 lepers segregated on the Island of Culion and a benevolent government has recognized the Filipinos' natural love of music by supplying instruments and uniforms for a band of fifteen men.

The six Sisters of Saint Paul de Chartres, who act as nurses at the leper hospitals, have always displayed a strong interest in the band and have advanced the training of its members to such a degree that the music is distinctly credible.

When a coastguard cutter arrives at Culion with a number of new patients the band blares forth a noisy welcome from the end of the big stone pier.



Band at Culion, P. I., composed entirely of lepers.

The leper is scarcely prepared for such an enthusiastic greeting and his face usually lights up with a broad smile, while he begins to feel that, after all, his seclusion may have its compensations.

It is not unusual to see a patient suffering from leprosy of the anesthetic type and minus several phalanges, pumping the keys of a wind instrument with the ends of his metacarpal bones. The deficiency does not seem to interfere with the volume or quality of the sound that may be elicited from this class of instruments.

A scrutiny of the photograph discloses evidences of the disease which has caused the segregation of the members of the band. It will be noted that a number of the performers, including the patients playing the cymbals, bass drum, snare drum, cornet, and tuba, are suffering from tubercular leprosy. The tuba player, near the center of the front rank, is afflicted with anesthetic leprosy.

The photograph was taken in front of one of the new, reinforced concrete tenement houses and illustrates the type of construction which is favored by the Bureau of Health for the housing of the Filipinos who are isolated at Culion.

The End Results of Cesarean Section. N. R. Mason.

Treatment of Miscarriage.—E. B. Young and J. T. Williams review the results of the treatment of two thousand cases of miscarriage at the Boston City Hospital. They conclude that spontaneous emptying of the uterus takes place in but about 13.2 per cent. of all miscarriages. The likelihood of a miscarriage to complete itself increases with the duration of pregnancy. When it becomes necessary to use artificial means to complete the miscarriage, the finger followed by the curette in later miscarriages and the curette alone in the earlier months of pregnancy have given uniformly satisfactory results. Experience has shown that where the cervix is extremely rigid it is better to introduce the curette and break up the fetus and placenta and remove them piecemeal than to attempt to dilate the cervix sufficiently to introduce the finger. Packing the vagina and lower segment of the uterus is an unsatisfactory and often unsuccessful method of emptying the uterus. No success whatever was obtained in treating incomplete miscarriages in this way. Packing is, however, of great value in two classes of cases: first, in exsanguinated patients, to stop the hemorrhage and give the woman a chance to recover somewhat from the loss of blood before emptying the uterus; and, second, when the cervix is very rigid, a tight cervical pack for twenty-four hours will soften it so that dilatation may be attempted with safety The results of artificial methods are as good as, but not better than, where nature has succeeded in emptying the uterus. Artificial methods are necessary in a majority of cases, however, simply because nature has failed. In infected cases the essential thing is to get rid of the infectious material by emptying the uterus: the particular method employed making little difference. The later in pregnancy miscarriage occurs the smaller the liability to become infected, but the greater the likelihood of developing grave septic complications if infection does take place. The mortality is practically the same at all periods of pregnancy. Induced abortions have a greater mortality than accidental. The mortality of patients admitted to the hospital after criminal abortions was 10 per cent.

Benzidin Test in Gastoenteric Diseases.—F. W. White believes that of all the blood tests the Schlesinger

and Holtz benzidin test is the best one to use, on account of its simplicity, clearness, and degree of delicacy.

Laboratory Work and Clinical Work.—R. C. Cabot states that the essential difference between clinical work and laboratory work is not in the technical methods employed, nor in the degree of their accuracy, nor in the methods of reasoning used. The essential difference consists in the predominance of physical elements among the data used in the wards, and their elimination in the laboratory. The clinician cannot safely utilize at the bedside the results of laboratory tests which he knows only by reading. He should familiarize himself with these tests in the laboratory, in order to understand the sources of error and the limits of reliability. No laboratory worker should remain out of touch with the clinical aspects of the cases which furnish him his material. In the absence of any single dominating personality as an integrating factor in the hospital system, the best available substitute seems to be combined ward visits in which the pathologist, surgeon, physician, chemist, and physiologist work together for the increase of their practical and scientific fruitfulness. The evils of specialism may be thus in a measure neutralized and its benefits enjoyed.

History of Cesarean Section.—E. T. Gray notes the great antiquity of this operation. The success of the present-day cesarean section is due largely to the following factors: strict aseptic precautions, early resort to operation before the patient's strength has been exhausted by lengthy efforts to extract the child by the natural passages, the careful and complete closure of the uterine incision, and a perfected technique.

Indications for Cesarean Section.—M. F. Hobart discusses the absolute and relative indications of cesarean section.

Technique of Cesarean Section.—M. A. Smith states that the conservative Sänger operation has become the operation of choice with the large majority of surgeons. By it the maternal mortality has been reduced to two or three per cent., and practically all healthy children delivered at term should survive.

Immediate Results of Cesarean Section.—J. T. Williams states that primary cesarean section is a simple and safe operation with a low maternal mortality. The mortality from cesarean section increases in direct proportion to the duration of labor, being only 2.7 per cent. in the primary, 5.7 per cent. in the secondary, and 13.7 per cent. in the late operation. Maternal morbidity as well as mortality is increased in the secondary and late cesarean sections. While there is no fetal mortality as a result of the operation where the fetus has been previously subjected to the strain of a long and difficult labor, the operation is frequently unsuccessful in saving the life of the child. The maternal mortality of 13.7 per cent., and the percentage of 13.28 of unsuccessful results for the child make the late cesarean section an unjustifiable operation.

End Results of Cesarean Section.—N. B. Mason discusses the following possible evil results of cesarean section: hernia, uterine fistula, adhesions, and rupture of the uterus.

Simple, Rapid, and Complete Reduction of Deformity in Fixed Lateral Curvature of the Spine. E. G. Abbott.
The Endobronchial Treatment of Asthma. W. Freudenthal.
An Operation for the Relief of Tuberculous Peritonitis. A. Judd.
The Injection of Magnesium Sulphate for Acute Articular Rheumatism. A. B. Jackson.
Diagnosis of Tuberculosis in Its Earlier and More Chronic Form. O. F. Kunkel.
The Contagiousness of Consumption of the Lungs. A. V. Meigs.
Guidance and Protection of Children by the State. J. Rosenberg.
In Memoriam Christian A. Herter. J. C. Hemmeter.

Lateral Curvature of the Spine.—E. G. Abbott states that lateral curvature of the spine is a deformity which yields to treatment as readily as clubfoot or bowlegs, and is curable even after it has become fixed in its distorted position through structural changes. One of the first principles in the correction of any deformity is not only to bring the distorted part back to its normal anatomical position, but to place it in an overcorrected position. Wolff, in his law of "functional adaptation," shows that, if any part of the anatomy is changed from the normal posture to the abnormal and habitually used, the structures involved undergo a change throughout their entire texture to adapt themselves to the new position. The converse is also true, *i.e.* if a deformity in which the parts involved have become changed in their shape is brought back to a corrected position and used, those parts again undergo a change and become normal in their contour.

Endobronchial Treatment of Asthma.—W. Freudenthal is convinced that there are asthmogenous points in the bronchi as well as in the upper respiratory tract. By attacking these points directly by topical endobronchial applications there has been laid the foundation for a new means of combating and conquering bronchial asthma. The author has treated in this manner fifty-three patients; of these twenty-one were cured by a single endobronchial application, and fourteen after repeated treatment. The other patients were more or less improved, while in seven there was no improvement. Among the drugs used, in addition to cocaine, were adrenalin and othoform emulsion.

Tuberculous Peritonitis.—A. Judd emphasizes the following points in his method of treatment of tuberculous peritonitis: 1. The use of hydrogen peroxide, fifty per cent., for diagnosis and to destroy the tubercles. 2. The thorough flushing of the abdominal cavity so that the peroxide may come in contact with all infected areas. 3. The necessity of primary union in which one is assisted by the peroxide. 4. The necessity of getting these patients out of bed at as early a date as possible. They do very badly if housed or kept on their backs. 5. The necessity of after-treatment in the form of hygiene, supernutrition, and appropriate drugs. The author states that the results of this method of treatment have been so spectacular as to seem almost miraculous.

Magnesium Sulphate in Rheumatism.—A. B. Jackson states that he has had excellent results in the treatment of five cases of acute articular rheumatism by means of intramuscular injections of magnesium sulphate. He injects one dram of a twenty-five per cent. sterilized solution of this drug, after other measures, such as the use of salicylates, have failed.

Tuberculosis.—O. F. Kunkel discusses the early diagnosis of this condition.

Contagiousness of Pulmonary Tuberculosis.—A. V. Meigs believes that the proof is still wanting that the tubercle bacillus is the one and only cause of pulmonary tuberculosis.

State Guidance of Children.—J. Rosenberg advocates the establishment of suburban colonies for the poorer classes, with close State supervision of the rearing of the young.

Christian A. Herter.—J. C. Hemmeter pays a tribute to the memory of the late Professor Herter.

A Case of Strangulated Hernia Presenting Unusual Symptoms. J. R. Judd.
Huge Hydronephrosis (Two Gallons' Capacity). H. J. Whitacre.

Meningitic Forms of Polioencephalomyelitis.—S. E. Jelliffe states that not enough emphasis has been laid on the meningitic forms of polioencephalomyelitis; the meningeal symptoms are more prominent than in the ordinary spinal type, in which, however, they almost invariably occur to some extent. Practically all patients show some signs of meningeal involvement in the early stages. Irritative phenomena of the spinal nerves with hyperesthesia, tenderness, irritability, etc., are the common signs of this spinal meningitis, whereas photophobia, hyperacusis, headache, and somnolence mark the implication of the cerebral membranes. The chief signs in the meningeal forms vary, in their initial stages, from those of the spinal type, only in the matter of greater severity. There are headache, nausea, and vomiting, slight photophobia with hyperacusis, pains in the neck and back, stiffness of the neck, rigidity of the muscles of the vertebral column, opisthotonos of mild or severe grade, Kernig's sign, tonic or clonic convulsive movements, somnolence, and even unconsciousness. The temperature runs a noncharacteristic course. While in the ordinary spinal type the disease develops in classical fashion, in the meningitic form it may recede rapidly, and beyond the possible occurrence of transitory or permanent eye palsies nothing remains. In some cases death ensues with the development of stormy symptoms.

Urine in a Case of Acromegaly.—A. W. M. Ellis notes the constant excretion of creatin in the urine of a female patient suffering from acromegaly. This case was interesting in view of the recent finding by Krause of a constant excretion of creatin in human diabetes mellitus and in phloridzin glycosuria in dogs. Krause is inclined to associate the excretion of creatin with the deprivation of carbohydrates in the food in these cases and Cushing has recently drawn attention to the close relation of the secretion of the posterior lobe of the pituitary gland to the storage of carbohydrates. The frequency of glycosuria in acromegaly, due probably to hyperactivity of this gland, has long been known. In the case reported, however, there was no deprivation or diminished tolerance of carbohydrates. Other conditions in which creatin has been discovered in the urine are starvation, cancer of the liver, progressive muscular dystrophy, and pregnancy.

Omental Endothelioma.—H. T. Karsner reports a case of primary endothelioma of the greater omentum and notes the extreme rarity of this condition.

Air-Water Sphygmomanometer.—A. J. Bendick describes an instrument in which he has utilized air compression as giving the simplest and most elastic compression. Its other advantages are sensitiveness and accuracy.

Tents in Intrauterine Medication.—E C. Dudley after noting the fact that dilatation by tents has gone into almost complete disuse, and mentioning the disadvantages of forced dilatation, its transient effect and its occasional inadequacy, describes a method of using tents in a relatively safe way in conjunction with thorough intrauterine medication. The device consists in the use of a tupelo sponge or sea tangle tent, over the distal end of which has been attached half of a gelatin capsule filled with whatever medicinal substance may be desired. Stress is laid on the necessity of thorough disinfection and asepsis of the tent at the time of use.

Trauma and Amyotrophic Sclerosis.—A. H. Woods reports personal observations of two patients in whom amyotrophic sclerosis developed after an injury to the hand in one case, and after a severe strain followed some months later by a fall, in the other.

Salvarsan.—J. S. McLester discusses the adjustment of the concentration of solutions of salvarsan to the osmotic tension of the body cells.

Antipneumococcus Serum.—P. Kyes concludes that it is possible to obtain from fowls after suitable inoculation a serum with specific antibodies to the pneumococcus.

Nitrates in Drinking Water.—C. C. Young reports the result of the examination of eight well-waters, which showed an excess of nitrate that would cause a person drinking a gallon of water a day to take in four diuretic doses. In every case a marked diuretic effect was produced in persons on first using the water, and in two of the eight cases the marked kidney irritation set up did not disappear in the customary use of the water. The symptoms reported were markedly noticeable and sometimes decidedly disagreeable, and chronic kidney trouble existed in some of the persons reported.

Methylene Blue Urinary Reaction in Malignant Disease.—J. Fuhs and W. Lintz give in a preliminary report their finding that methylene blue is decolorized by the urine of patients with malignant disease. The same is true sometimes in cases of rheumatism, nephritis, meningitis, etc., but generally to a minor and variable degree. In most instances these latter diseases can be easily differentiated and eliminated, so it seems that the test may have some value in the diagnosis of malignant disease. Thus far it has been positive in every well-established case of malignancy in which the test was performed.

Strangulated Hernia.—J. R. Judd reports a case of strangulated hernia that had lasted four days before being seen. The abdomen was greatly distended and tympanitic and there was considerable pain. Operation revealed a gangrenous intestine involved in the hernia, twelve centimeters of which were excised together with a wedge of mesentery, and an end-to-end anastomosis was made with sutures. There was gangrene of the right testicle, which was also removed. This was due to pressure from the sac and its contents. The author specially notices the absence of vomiting in this case after so long a duration of the strangulation, vomiting being given as almost an essential feature in the text-books.

Hydronephrosis.—H. J. Whitacre presents an account of a woman, aged 68, who showed an enlargement of the abdomen equal to a seven or eight months' pregnancy, the physical signs and her age all pointing to the existence of a large ovarian cyst, which diagnosis was made. Her trouble dated back for twenty years and the tumor for sixteen, and it was diagnosed at that time as gas accumulation and obstruction. Operation showed that the cyst was not attached to either ovary and was retroperitoneal. The peritoneum was divided over the cyst and two gallons of fluid were drawn off with a trocar.

Sanatoria from Within. J. E. Esslemont.
Case of Recurrent Carcinoma of the Parotid Gland Treated With Coley's Fluid. E. R. Hunt.

Pyelography and Dilatation of the Kidney.—J. W. T. Walker states that it is not possible by symptoms alone to make a diagnosis of early dilatation of the kidney. Kelly's method of determining the capacity of the renal pelvis by means of injecting the latter with a warm and bland solution and noting when the patient first experiences pain is associated with certain difficulties and fallacies. Thus in a pronounced degree of hydronephrosis, when the kidney is distended the pain is slight. Some fluid may escape alongside the ureteral catheter. Moreover, with an abundant polyuria it is impossible to empty the renal pelvis completely. Radiography offers more definite information.

Pyelography, however, is the most accurate method. By means of a ureteral catheter a 10 per cent. solution of collargol is introduced into the renal pelvis and then a radiograph is taken. In some cases a severe attack of renal colic follows the examination.

Vaccination in Regard to Life Insurance.—W. H. Jalland states that whereas in 1903 out of 57 insurance companies 11 altogether declined unvaccinated lives, only 6 received them without either extra premium or restriction, 11 accepted them without extra premium but excluded death from smallpox, while 19 accepted them at an extra premium; in 1910 the number of such companies declining unvaccinated lives had fallen to 3 out of 68, while those accepting them without extra premium or restriction had risen to 24. The other two classes had risen only slightly —viz., to 13 and 28 respectively. A question that we might put to ourselves is: Has the risk from a medical point of view diminished to the extent indicated by the present practice of the majority of British insurance companies? A further question might also be considered arising from the fact that the English companies are now accepting business more or less all over the world. To what extent are European lives jeopardized by the risk of contact with natives among whom smallpox may be rife? There can be no doubt that very considerable good has been obtained through enforced vaccination, and when in addition it is remembered that the improvement in the sanitary laws, the isolation now compulsory and also the compulsory notification of infectious diseases have largely added to the present conditions of security, one need not, perhaps, have had such great doubts as to the lessened restrictions insurance companies have been taking with regard to vaccination if one were satisfied that there would be a continuance of the safeguards imposed by the legislature. Recent action, however, may give rise to a doubt on this point in consequence of the exemption that has been allowed on the ground of conscientious belief on the part of the child's parent or guardian that vaccination will be prejudicial to health. When that exemption was granted it was taken advantage of to a very considerable extent in England and Wales, and one finds that 203,413 exercised it in 1898. In subsequent years up to 1907 the numbers were much smaller, being reported in the last-named year as 57,675, but in 1908, when the regulations were still further modified with regard to the conscientious objector, exemption being granted on a statutory declaration before a justice of the peace or other authority without the ordeal of proving his case to the satisfaction of a magistrate in open court, one finds the number increased to 162,799, rising again the next year to 190,689, while for the first half of 1910 Mr. Burns in the House of Commons reported that 110,851 exemption certificates had been received as against 456,533 births registered in England. This means that today about one-fourth of the children in England and Wales are going out into the world unvaccinated, and one realizes that if this continues in the same proportion it will be found in the next generation that every fourth individual met on the streets is unprotected by vaccination. Will the undoubted benefits of the laws as to sanitation under such circumstances be sufficient of themselves to maintain the present good that has been secured against the ravages of smallpox? The author believes that this is greatly to be doubted and that one must sound a note of warning to the insurance companies, so that it may be clearly seen what the issue is that lies before them. If there is risk of the introduction of the disease from other lands, many of which are not nearly so careful in respect of preventing smallpox, either from the persons of those coming from those lands or through the introduction of such merchandise as rags, hair and the like, it seems incumbent on one to maintain all the means that have been raised as defenses against smallpox, and it is a consideration, therefore, whether with regard to business coming to be insured the company should not maintain the attitude of 20 years ago—viz., either to insist on vaccination or to put upon the policies certain emphatic restrictions regarding unvaccinated lives. Recent epidemics of smallpox have demonstrated the protective value of vaccination and particularly of revaccination. A table presented by the author demonstrates that a fall in smallpox mortality occurred exclusively in the young. Among adults there was a rise, increasing with the older ages, i. e., in proportion to the length of time that had elapsed since vaccination. Germany is an excellent example of what can be done by efficient vaccination. There vaccination within a year of birth and again during school life is compulsory by law. For 25 years Germany has had very little epidemic smallpox, although the disease has been frequently introduced into frontier towns and districts. It is mentioned that many insurance companies say that they have had few claims due to death from smallpox for many years. The author admits that this may be so, but, he asks, is not the future bristling with danger? Medical men ought to throw the weight of their opinion into the scale and urge upon the various companies that it is both dangerous and injudicious to ignore the protective influence of vaccination.

Salvarsan.—A. Fleming and L. Colebrook note the remarkable effect of this drug in causing the lesions of syphilis to disappear. They do not venture an opinion as to the possibility of its displacing mercury in the treatment of this disease.

Postanesthetic Vomiting.—J. D. Mortimer notes among the causes of this condition the following: (1) the habitual state of the patient, (2) the disorder which led to the performance of the operation, (3) the faulty preparation, (4) the anesthetic or the way in which it is given, (5) swallowing of mucus, blood, etc., (6) the operation or some complication following it, and (7) faulty after-treatment. The anesthetic and method must be carefully chosen with regard to all the circumstances, including possible after effects. The administrator should do everything possible to maintain a free air-way and subdue rigidity. Glucose is valuable both before and after operations, not only to prevent or combat acid-intoxication, but as a food which makes no call on digestion. A tablespoonful can be given with water and lemon juice three times or more in the 24 hours, or in special cases it may be given by the rectum or intravenously (2.45 per cent.) Raisin tea contains an appreciable amount.

Infective Endocarditis.—J. A. Venning emphasizes that he has not attempted to adduce evidence that all cases of infective endocarditis with a history of previous attacks of rheumatism are rheumatic in origin. In 7 cases out of 27 due to an obvious infective focus there was a rheumatic history, but no one would hold that these cases are due to and are part of a rheumatic process. There are also many cases in which there is no obvious cause found, but which have a rheumatic history, yet one cannot say that they are due to the rheumatic diplococcus. Undoubtedly the causation of these cases is very varied. But the evidence adduced, both from the bacteriological work of Poynton and Paine and from that obtained by the study of the author's series of cases, is in favor of the view held by Osler in 1885—namely, that infective endocarditis, supervening in the course of some particular disease as rheumatism or pneumonia, may be regarded as directly produced by the causes which have excited the original disease.

Sanatoria from Within.—J. E. Esslemont discusses the tuberculosis sanatorium not so much from the strictly scientfic point of view as from the more human and personal one of the sanatorium inmate.

Coley's Fluid in Parotid Carcinoma.—E. R. Hunt notes the complete relief of pressure symptoms and the

very marked relief of pain which he attributes to the action of Coley's fluid in causing the sloughing away of the greater part of a carcinoma of the parotid gland in a case that he reports.

Note on the Blood in Sympathetic Ophthalmia. C. P. Jones and S. H. Browning.
Bonesetting and the Treatment of Painful Joints. F. Romer and L. E. Creasy.

Chemistry and Medicine.—A. E. Garrod discusses the thesis that chemistry is able to lend valuable aid in the solution of problems of clinical and practical importance to medical men and helps materially as a guide to treatment. On the other hand, one must not expect from chemical studies more than they can reasonably be expected to give. Unlike the bacteriologist who deals with the actual *causæ causantes* of many morbid states, the chemical pathologist can only study the response of the organism to morbific agencies. He can tell one much concerning the forms which disease takes and the origin of symptoms, but comparatively little as to the actual causation of maladies. The author mentions examples of phenomena which can be studied by ordinary chemical methods which are accessible to the test-tube and the balance, but the advance of bacteriology is revealing responses of the organism of much more subtle nature still and has familiarized one with substances known by such names as antitoxins, and agglutinins, precipitins, and the like. The phenomena of immunity have doubtless a chemical basis, although the substances concerned are known as yet only by single properties, just as, for a number of years, the planet Neptune was only known by its disturbing influence upon the orbit of its nearest celestial neighbor Uranus. Now, Neptune has been seen, weighed and measured, and has taken its place as a regular member of the solar system, and one may reasonably hope that in due time the substances mentioned above will in like manner be brought within the grip of the chemist and will rank as compounds of known constitution and molecular structure. Obviously the realization of this dream will result in an immense extension of the field in which chemistry and medicine meet.

Toxemia of Pregnancy and Hemorrhage.—R. Davies-Colley reports a series of cases of toxemia of pregnancy treated at Guy's Hospital during the last 11 years. Investigation of their records has shown that hemorrhage in one form or another is not a very infrequent symptom of the disease, and that in some cases it may be so great as to constitute its principal feature. The cases of hemorrhage fall into three groups: (1) hemorrhage from the kidneys, (2) hemorrhage from the uterus, and (3) purpura and hemorrhage from the mucous membranes.

Preparation of Wheat and Rice and Relation to Disease.—E. S. Edie and G. C. E. Simpson state that it has been conclusively demonstrated that the cause of experimental polyneuritis and of tropical and ship beriberi is connected with deficiency of organic compounds of phosphorus—though whether the deficiency is of nucleins, lecithins, phosphatids, phytins or other classes is as yet undetermined. The minimum phosphorus requirement of an adult man at work is about 2 grams, and it would seem that the higher animals have not been endowed by nature with the power of preparing their own organic compounds of phorphorus from inorganic phosphorus. These bodies are of far-reaching importance to the bioplasm, indeed, are indispensable, and their absence or deficiency in the food supply will lead to serious symptoms or even to death. Experimental polyneuritis in animals is produced on the one hand by diets of substances such as rice, barley and white wheat flour in which the outer layers of the grains have been removed by milling and in which the proportion of phosphorus is very low. On the other hand, it is originated by foodstuffs which have been heated for a time to a temperature of 120° C. (especially in the presence of alkali) by which the organic phosphorus compounds have been partially broken down and by substances from which the same compounds have been extracted by long exposure to solvent action. Adult pigeons, previously on ample mixed diet, were fed exclusively on good white wheat bread guaranteed from unbleached and unadulterated flour. They ate it readily and greedily, but loss of weight and diarrhea soon commenced; the other symptoms of polyneuritis followed, and the first bird died on the fifteenth day. The authors make a plea for the more general use of whole-wheat bread, particularly for children.

The Average Height and Weight of English School Children.—H. W. Tuxford and R. A. Glegg present tables compiled from the examination during 1909 and 1910 of 583,640 school children. The children were measured and weighed in ordinary indoor clothing and without boots. The figures were received from 17 country and 44 urban education areas scattered throughout England. Among the tables given the following represent the results for England as a whole, including both city and country:

Average Height and Weight of English School Children.

Age last Birthday.	Boys.			Girls.		
	No.	Height. Cm.	Weight. Kilos.	No.	Height. Cm.	Weight. Kilos.
3	9,388	92.4	14.86	8,478	91.6	14.44
4	24,047	98.2	16.29	21,362	98.1	15.82

Weight and height curves constructed from the tables show certain irregularities, the most marked one of which is the elevation at age 12 in the boys' height curve and in both the boys' and girls' weight curve; this is probably due to the fact that children leaving school are more likely to be inspected toward the end than the beginning of their twelfth year, and the averages for this year are probably greater than the true mean. The elevations in both height curves at age 7 and in the girls' height curve at age 10 are not accompanied by any corresponding deflection of the weight curves, and the authors are unable to account for them. They constructed curves for the subsidiary areas and found that, generally, those for the urban areas were the most regular, those for the county areas being least so. The height and weight of girls are a little less than those of boys until the eleventh and twelfth years, when the relative positions become reversed.

Diagnostic Value of Rachicentesis.—J. Rae discusses this subject and reports six cases.

Sympathetic Ophthalmia.—C. P. Jones and S. H. Browning note the increase in the relative percentage of the large uninuclear cells in this condition.

Bonesetting.—F. Romer and L. E. Creasy conclude their article on the manipulative treatment of painful joints.

Vaccination in Regard to Life Insurance.—(See page 87.)

The Work of the Insurance Companies in the Prevention of Disease.—At the fourth annual meeting of the Association of Life Insurance Presidents, held in Chicago in December, 1910, Dr. Eugene H. Porter, Health Commissioned of the State of New York, delivered an address entitled "The Fight Against Preventable Diseases," in which he noted what had already been accomplished by the various agencies engaged in the work of sanitary betterment and pointed out what could be done to further this movement by the insurance companies. While much has been done in clearing away the mists surrounding the causes of disease—the first step toward prevention, the actual results in this direction have not been all that could be desired. In the preventive warfare against disease the skirmish lines of the opposing forces have come together, and the enemy have been discovered, strongly entrenched and protected by the troops of selfishness and ignorance. The fact must, however, be faced that the preventable diseases are not now prevented, and are not likely to be entirely prevented for many years to come, but we are in position to begin a campaign for their ultimate practical extinction. The one great weapon in this fight for prevention is education of the people, for without the cooperation of the public, based upon an intelligent comprehension of the value of the work of the sanitarian, the enforcement of health laws is impossible. Sanitarians may know how to prevent disease, but what they will be actually able to do will be little until at least some of the knowledge they possess is disseminated among the people.

The grand army of health is made up of many divisions. "It embraces those bureaus at Washington where health work is of national significance; it numbers all the state health departments; it enlists all the municipal and local boards of health in every state and territory; it counts all the great hosts of organizations that labor for the betterment of human conditions; it involves those that fight for better tenements, for pure air, for pure foods, for pure water, for more playgrounds, for shorter hours of labor, for prevention against avoidable accidents, for better protection of working women, for proper care of children, for the checking of tuberculosis, for civic improvement, and for municipal reform." But there is still a legion, already well equipped for the war, which should enlist in this campaign against preventable disease—the legion of the insurance companies. The reasons why the companies should enlist for this war are: (1) There is nothing to prevent; no law could be invoked against a well-considered effort on their part to prolong life and to increase their income and strengthen their position as trustees of the funds of the people. (2) They already possess an efficient and highly trained body of workers in the 80,000 medical examiners and 20,000 agents in the field, in close relationship with 20,000,000 policyholders, a great army of potential instructors whose sanitary counsels would be attentively received and seriously weighed. Indeed, the speaker said, he knew of no one single agency in all the wide field of sanitary effort so potentially powerful for public health. The thing of importance is the fact of systematic organization followed by immediate and persistent work along the lines indicated.

In conclusion Dr. Porter offered the following outline of a possible plan of work for the insurance companies: (*A*) The immediate establishment in each insurance company of a department of health; (*B*) a cautious and judicious selection of the lines of activity to be followed; (*C*) an immediate moving along those lines. As to what these lines of activity should be the following were suggested: (1) The instruction of medical examiners and life insurance agents in sanitation and preventive disease work; (2) the issuance of a carefully arranged series of letters or circulars on health topics to policyholders. (3 The establishment of a health magazine or health bulletin. (4) The arranging for a series of public health lectures in various cities and towns, with or without the cooperation of State or local health authorities. (5) The systematic use of the tremendous educational power of the press. (6) Conjoint work with State and city health departments. (7) Conjoint work with all organizations interested in public health work. (8) The securing of more uniform and better health laws, and (9) of the establishment of a National department of health. (10) Aiding in securing adequate appropriations for health work. (11) The free reexamination of all policyholders. (12) A special investigation of the causes of pneumonia, Bright's disease, diabetes, apoplexy, and cancer. (13) Making available, as Dr. Dwight has suggested, that great abundance of experience now in possession of the insurance companies—a gigantic collection of facts that should be of incalculable value. (14) Education, and again, education.—*Proceedings of the Fourth Annual Meeting of the Association of Life Insurance Presidents, December 9 and 10, 1910.*

Height and Weight in Relation to Life Insurance.—In a paper read before the Royal Arcanum Medical Examiners' Association of Greater New York and vicinity, George F. Little states that height and weight in relation to each other are of great importance in estimating the value of an insurance risk. Age is now also recognized as playing an important part, for there is a tendency to a gain of weight with increasing years. The present table of the Royal Arcanum figures at the height of 5 feet 10 inches a standard weight of 154 pounds, at the age of 21 to 25; but at the age of 51 to 55, 172 pounds is allowed, a difference of 18 pounds. The ideal insurance risk, as regards height, is said to range from 5 feet 7 inches to 5 feet 9 inches. The greater the variation from these figures the greater is the risk. Longevity is not as great in tall men as in short men. Men who are both tall and stout are poorer risks than men who are stout and of medium or short stature. The former do not bear accidents or acute illness as well. Individuals of excessive weight are especially liable to diabetes, heart affections, apoplexy, gout, diseases of the kidney, and arteriosclerosis; excessive eating and abuse of alcohol are common among this class. Gossage's analysis of 5,375 claims shows that of 285 overweights 19, or 6.6 per cent, died of diabetes as compared with 65 or 1.28 per cent. of the 5,090 who were not overweight. Stout men under 40 are worse risks than those over 40 and under 60, and men who were unduly fat before puberty are poor risks, especially if the tendency is hereditary (Keating). Stout men are, however, better average risks than their very thin brothers, who are liable to tuberculosis and nervous disorders. The underweight bears acute illness better than the overweight and the majority of long-lived people are of light build. The necessity of the examiner possessing an office scale is seen in the fact that many men either do not know their own weight or else try to deceive the examiner. The Royal Arcanum allows 25 per cent. above and 20 per cent. below the standard weight. Of great importance is the tendency to steady gain or loss in weight. In the latter, if not due to laborious work, grief, indoor confinement, or change of occupation, tuberculosis or other organic disease may be suspected. If there is continued loss from any cause, the risk is not acceptable for the time being. In steady gain, unless in recovery from acute illness or beneficial change in occupation, the risk is undesirable at the moment. It is important to ask the applicant before weighing him the questions: "What is your usual weight? What was your last weight? What did

you weigh a year ago?" In all cases unduly stout or thin the family weights and measurements, as far as possible, should be noted as showing possible heredity, which is of value if longevity is also shown. In underweights it is important to note whether the chest is flattened or narrow, whether the supraclavicular spaces are retracted or the expansion lessened. Is the muscular development fair? Does the man stand erect or stoop and hollow his chest? Is he large or small of bone? Is his face of good color and soft in lines or does it evidence wasting? Greene states: "If an underweight has a well developed and free expanding chest, if his health record is good, his family long lived and free from tuberculosis, and particularly if the light weight is a family trait, he may be accepted at ordinary rates, even if 20 per cent. below tabular weight. If on the other hand these favorable features be lacking he cannot be given so much latitude." In considering overweight the following points are of value: The measurement of the abdomen should not exceed that of the chest, for this indicates a heavy deposit of fat. A sedentary occupation detracts from the value of the life. A pulse persistently rapid evidences lack of cardiac strength. In the very stout subject the heart is best listened to with a phonendoscope. Note whether there are signs of the overweight being due to alcohol, dilated facial capillaries for example, skin affections being excluded. Abundant muscular tissue over the chest and arms is a matter to be noted in the applicant's favor.—*American Medicine*, May, 1911.

Height and Weight of English School Children.—(See page 88.)

Longevity, Race, or Environment.—H. Josse Johnson says that each and every characteristic of race has been simply and solely due to difference of environment in the past. Statistics as to the exact value of life among the different races are meager, and available only for a small proportion of the peoples of the world, and we are therefore obliged to feel our way and gain our experience of the value of life among the rest as best we may. The effect on longevity of cleanliness, that is frequent bathing, is slight. The factors that tend to longevity are (1) heredity; (2) the climate of the country; (3) other surroundings, occupation, education, etc.; (4) the average height and weight; (5) chest development and capacity; (6) proportion, *i.e.* distribution of weight. Heredity is probably the most potent factor. Climate is also an important factor. The hotter the climate the more quickly does the vital elasticity get used up. In Europe the increase of mortality is greater as the heat increases. Spain is almost the only exception to this rule, but the high average mortality in Spain may be almost wholly attributed to the tremendous infant mortality. Environment tells somewhat against the Anglo-Saxon race and the nations of northern Europe, in that they live for the most part in densely populated districts and lead a strenuous life. On the other hand these factors are greatly counterbalanced by the advantages of education, the spread of sanitary science and of preventive medicine. The recognition of the germ theory of disease is the origin of the improvement in health of the industrial nations, and the basis upon which the whole of preventive medicine rests. If it were not for the alcohol habit the nations of the Teutonic race and of the more temperate climates would compare still more favorably with their relatively lethargic brethren of the hotter zones. The average height of the adult males of the white race differs so slightly as to be an almost negligible quantity and the average height of all races with which insurance physicians have to deal comes well within the limits which experience has taught are not abnormal. The extremes, above 75 and under 60 inches, have proved a very short-lived class. As to average weight in white races, this does not vary much more than the average height. Overweights of any race do not offer the same resistance to disease as men of the average standard. It is generally accepted that a well-built man has a thoracic circumference which measures at least half the height. In those countries which have compulsory military service the average chest measurement is greater than in those countries which have not. However, Johnson considers it doubtful whether the military chest is an advantage from the insurance standpoint. The chief points of build are the size of the abdomen in comparison with that of the chest and of the latter to the height. No man under 40 years of age should have an abdominal measure in excess of the chest. Elaborate comparative statistics are given of the vitality of the different European races and the conclusion is reached that the Scandinavian race stands so easily first that to it must be conceded some superior innate vitality, while the Jews living under varied circumstances and surroundings are proverbially long lived.

The final conclusions of the author are that environment is the immediate factor, and makes itself felt and evident at once. It also acts more remotely in that it weeds out the unfit and weakly, and so improves the stock of any race. Race is the remote and determining factor which can and does predominate over any environment. This is true of the Jews who are characterized by their greater longevity, and of the negroes who are characterized by their lesser longevity, when compared with the mass of the population under the same environment.—*Transactions of the Life Assurance Medical Officers' Association*, London, 1910.

Census Data and Their Interest for Medicine.—Krevet has analyzed a few census returns for the town of Mühlhausen, with the population of over 35,000; 950 inhabitants had reached the age of 70 or over, and of these 554 were women. Five persons over 90 years of age were all of the female sex. These data answer the general belief of the exceptional longevity among women. As a rule these aged persons belonged to the middle class of society. Many of the women had borne many children. They were mostly of medium stature, not obese, and gave a history of sound digestion through life. None ever took any gymnastic exercise, or massage; none were teetotallers or vegetarians; none spent their holidays at the seashore or in the south none frequented sanitaria or mountain resorts. Most of them slept in ill-ventilated quarters. The great majority had labored all their lives. One woman of 94 years had been a cripple—a hunchback—since 30 years of age, yet she bore 15 children. At 80 she broke her femur, and had been an invalid since. Krevet thinks that a study of statistics and observation of aged people may throw light upon the question of longevity.—*Blätter für Vertrauensärzte der Lebensversicherung*, March and April, 1911.

State Insurance in Italy.—A bill is before the Italian Parliament, with, it is said, every prospect of becoming a law, designed to make of life insurance a State monopoly. The bill provides that in future all insurance companies, Italian and foreign, shall cease to get new business in that country, but may continue their work for the present policyholders only. There will be no compensation for contracts made in Italy or abroad after the proposed bill becomes a law. Such contracts will be null and void and policyholders who violate this provision are to be subject to a fine of from 5 to 20 per cent. of the amount insured and imprisonment for a term of from one to six months. The foreign companies are protesting against the proposed lines of the bill, alleging violation of acquired rights. The capital of these foreign companies in Italy reaches a total of $186,000,000. Of this $28,000,000 belongs to American companies.

The Typhoid Death Rate.—From 1901 to 1905 the annual death rate from typhoid fever for the countries named was as follows: Scotland, 6.2; Germany, 7.6; Austria, 19.9; Hungary, 28.3; Italy, 35.25, and for the United States, 46. These figures, according to Dr. Huber, mean that in a single year we Americans have averaged 400,000 cases and 35,000 deaths from this one preventable disease.

Book Reviews.

Diseases of the Stomach and Upper Alimentary Tract. By Anthony Bassler, M.D., Visiting Gastroenterologist to the People's Hospital and Visiting Physician to the St. Marks Hospital Clinic; Member of the American Gastroenterological and American Medical Associations; Fellow of the New York Academy of Medicine, etc. Copiously illustrated with numerous half-tone and line text engravings and 56 full-page half-tone plates (with nearly 100 figures), plain and in colors, from original photographs and drawings. Philadelphia: F. A. Davis Company, 1910.

From the standpoint of size, this book, of over 800 pages, must rank as one of the larger works on diseases of the stomach. The first three chapters deal with the anatomy, physiology, and chemistry of the parts concerned. Then follow chapters on anamnesis and on the examination of patients, of gastric contents, and of feces; and these are among the most satisfactory portions of the book. Various methods of treatment are then considered, also the indications for surgical intervention. The latter half of the volume treats of the various gastric diseases in detail. The book has several good features. It represents much original work on the part of the author; it is not so narrow in scope or teaching as works on this subject are apt to be; the illustrations are unusually good, and the volume is exceedingly well printed; some of the chapters (so far as their contents are concerned) leave very little to be desired. But, on the other hand, the author's style is often turgid and involved, and it is sometimes very difficult to find out what he really wishes to say; the prescriptions are a curious blend of English, Latin, and some nondescript dialect which is probably meant for Latin. There is quite a little very elementary matter which readers of a volume of this size and caliber might safely be presumed to know. Omitting numerous misprints, the author makes use of such expressions as "chronic gastrides," "the feces collects," "the feces is," "good results is due," "bona fidely so," "bona fidely due," "hypermotility nervosa," etc. As a sample of his style we quote (from page 399): "On the other hand, because of the high rates of mortality in surgical procedures of the gastro-enteron, the desirability of practical knowledge of what is wisest to do to obviate or remove the error when the abdomen is opened and the condition is observed, a skilled hand in the way of the various operative procedures pertaining to the surgery of the digestive tract, and the importance of perfect work quickly done, necessitating as it does a good understanding of the anatomy and physiology of the parts, the time has arrived for the existence of special surgeons who have aptitude for this class of work, and whose skill, born of ample experience, is beyond that of the more general surgeon." As an illustration of the lingua franca of prescription writing we append (from page 319):

℞. Sodæ bromidum.
Fldext. cascara sagrada, āā 10.0.
Liq. ferri albuminatum, 100.0.
Fiat et Sig: etc.

And on the following page: "Fiat capsulæ or soft pills no. xxx."

In another edition this should be translated into either Latin or English.

An Introduction to Surgery. By Rutherford Morison, M.A., M.B., F.R.C.S. (Edin. and Eng.), Professor of Surgery, University of Durham, College of Medicine, Newcastle-upon-Tyne, Senior Surgeon to the Royal Victoria Infirmary. With 146 illustrations in the text and 5 colored plates. Price, $2.50 net. New York: William Wood & Company, 1911.

Within the limits of this volume of 167 pages the author has succeeded in presenting the fundamental principles of modern surgical science. The book is not designed to take the place of the larger textbooks, but is offered as a supplement or as an introduction to these. The real need of a book like this is manifest when one considers the facts that the principles of surgery are relatively few; that it is important that the student should have a clear conception of these principles in order that he may intelligently interpret the multitude of surgical conditions that affect the different parts of the body. The present volume is an abstract of the author's lectures which have been framed wth the idea of emphasizing the main principles of diagnosis and treatment that are based on a sound knowledge of pathology. As an illustration of the method by means of which the author strikes at the fundamental principles of surgery, may be cited the chapter on syphilis, tubercle, and malignant disease. These are first considered together; their numerous points of resemblance and difference are tersely described, as regards the primary lesion or focus, the glandular enlargement, and the mode of dissemination. This takes in the diagnosis of the three diseases, which are treated at some length. The relation of fibrosis to the three conditions, the manner in which the bones are involved, the influence of septic infection on the primary disease, and the characteristics of combinations of syphilis, tuberculosis, and malignant disease are all presented in a manner which is unique in surgical textbooks. The three conditions are then separately discussed in detail. Another illustration of the application of broad general principles to special conditions is splendidly furnished by the section dealing with inversions and torsions of the hollow viscera. It is noted that "whatever organ the twist involves, and whether viewed in reference to etiology, pathology, symptoms, diagnosis, prognosis, or treatment, all cases have many points in common." These points are dwelt upon. Several pages are devoted to the subject of certain protective functions of the omentum, with numerous illustrations showing its relation to hernial sacs, to damaged loops of intestine, to the locking up of pus from an appendix abscess, to perforated hollow viscera, and to the isolation of pelvic tumors. Its extraordinary capacity for the formation of new blood-vessels is pointed out. In addition to the general principles the text contains many suggestions of practical value in the surgical treatment of special cases. Thus the discomforts and dangers of plugging of the posterior nares are pointed out, while it is stated that by careful plugging through the anterior nares it is possible to arrest any ordinary hemorrhage from the nose. The treatment of tuberculous abscesses by means of a small incision and the use of Klapp's suction ball shows that the author is alive to modern advances in surgical treatment. While this book has been written primarily for the student, there can be little doubt that the general practitioner will greatly profit by a perusal of its pages. The text is concise, without being schematic and unintelligible, and the style shows the natural elegance and precision of the mature scholar. The numerous illustrations and colored plates are of a particularly fine order, and together with the excellent paper and typography contribute to make this book an ideal one in its particular sphere.

Gynecological Therapeutics. By S. Jervois Aarons, M.D. (Edin.), M.R.C.P. (Lond.); Gynecologist to St. Anthony's Hospital; Fellow of the Royal Society of Medicine; Member of Obstetric and Gynecological Sections; formerly Registrar and Pathologist to the Hospital for Women, Soho Square; Gynecological Tutor, Extramural School of Medicine, Edinburgh; House-Surgeon, Gynecological Ward, Royal Infirmary, Edinburgh. With Foreword by Sir Halliday Croom, M. D., F.R.C.P., F.R.C.S.; Professor of Midwifery in the University of Edinburgh. $2.00. New York: William Wood & Co., 1910.

In this small volume of 175 pages the symptomatology, diagnosis and operative treatment have been entirely omitted, and the book devoted exclusively to medical gynecology. Except for some of the prescriptions given, and the mention of the use of the *x*-ray and radium, the author recommends no treatment which he himself has not carried out. In general, the therapeutic measures mentioned by Dr. Aarons are in line with what, in this country, is considered good gynecological practice. However, we do not agree with him in his management of ectopic gestation, when there are signs of internal hemorrhage and the practitioner has to wait for the arrival of a surgeon before an operation can be done. Quoting from the book, "The patient should be kept flat upon the bed, the foot of which should be raised about eighteen inches. A normal saline infusion may be given, to which a little adrenalin has been added." Again, "A hypodermic injection into the gluteal region of pituitary extract (1 cc.) will help to allay the shock." We do not consider this good advice, as the saline infusion and the pituitary extract, by raising the blood pressure, will tend to increase the hemorrhage from the ruptured blood vessels, and therefore ultimately increase the shock. The time for the use of these measures is when the blood vessels have been ligated, during or after the operation. If any medication is needed while waiting for the operation hypodermic injections of morphine should be given, as morphine allays the restlessness which follows the loss of large quantities of blood, and thus favors the clotting of the blood in the ruptured vessels. The book is one that cannot fail to be of great service to the general practitioner, and it would have been even better had the author gone a little more in detail into the methods of treatment which he describes.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Sixty-Second Annual Meeting, Held at Los Angeles, Cal., June 26, 27, 29, and 30, 1911.

(Special Report to the MEDICAL RECORD.)

(*Continued from page 52.*)

HOUSE OF DELEGATES.

Thursday, June 29—Fourth Day.

THE PRESIDENT, DR. JOHN B. MURPHY OF CHICAGO IN THE CHAIR.

Election of Officers.—The following officers were elected for the ensuing year: *President*, Dr. Abraham Jacobi of New York City; *First Vice-President*, Dr. W. Jarvis Barlow of Los Angeles, Cal.; *Second Vice-President*, Dr. Floyd W. McRae of Atlanta, Ga.; *Third Vice-President*, Dr. William R. Tipton of Las Vegas, N. M.; *Fourth Vice-President*, Dr. A. L. Wright of Des Moines, Ia.; *Secretary*, Dr. Alexander R. Craig of Philadelphia, Pa.; *Treasurer*, Dr. W. A. Pusey of Chicago, Ill. Three *Trustees* elected to serve until 1914 were: Dr. Philip Marvel of Atlantic City, N. J., to succeed Dr. Wisner R. Townsend of New York City; Dr. Philip Mills Jones of San Francisco, Cal.; and Dr. W. T. Sarles of Sparta, Wis., to succeed himself; *Chairman* of Committee on Transportation and Place of Session to serve for three years, Dr. J. R. Pennington of Chicago, Ill.; *Member of Council on Health and Public Instruction*, Dr. H. B. Favill of Chicago; *Member of Council on Medical Education*, Dr. J. A. Witherspoon of Nashville, Tenn.

Election of Honorary Members.—Mr. Howard Stiles of Edinburgh, Scotland, was unanimously elected an Honorary Member of the America Medical Association.

Supplementary Reports from Reference Committees.—Dr. G. W. Guthrie made the following recommendations in behalf of the Committee on President's Address: That a committee of five be appointed by the President to arrange a series of lectures and exercises for those attending the next annual meeting of the Association. That the President appoint a committee of five to arrange for clinical meetings on the day before and the day after the next meeting of the Association. That the President appoint a committee of five to investigate and report on the advisability of publishing a small medical journal for distribution among the laiety. That a committee of five be appointed to represent the American Medical Association at the Association of American Educators which would meet in San Francisco in July.

The President was authorized by the House to appoint these committees.

The Committee on Sections and Section Work presented resolutions requesting the House of Delegates to support their efforts to raise the standard for practitioners of ophthalmology so that every ophthalmologist should be a graduate in medicine and have one year of clinical work before entering upon the practice of ophthalmology.

The House adopted these resolutions.

New Section on Hospitals and Hospital Work.—The House of Delegates adopted resolutions forming this new section and the President appointed Dr. Witten Booth Russ of San Antonio, Tex., president, and Dr. A. L. Brittin of Athens, Ill., secretary.

The Committee on Hygiene and Public Health, in behalf of the Section on Preventive Medicine, presented resolutions providing that a committee be appointed to investigate in regard to the prevalence of syphilis and gonorrhea in this country and to report at the next meeting; also that a committee be appointed to confer with a committee from the Association on Sex Hygiene as to the best methods to pursue in the investigation of these questions and the best means of lessening or suppressing these diseases. They also recommend that this committee consider the advisability of reporting these diseases and that the subject be brought before the House at the next meeting.

The Judicial Council.—In compliance with resolutions adopted by the House creating a Judicial Council and providing that the President appoint five members to serve, Dr. Murphy appointed the following to serve from one to five years in the order named: Dr. Hubert Work of Pueblo, Col.; Dr. James E. Moore, Minneapolis, Minn.; Dr. Alexander Lambert of New York City; Dr. A. B. Cooke of Nashville, Tenn., and Dr. Frank Billings of Chicago.

On the Admission of the Medical Society of Porto Rico.—In regard to the resolution providing for the admission of the Medical Society of Porto Rico the reference committee decided that the constitution of the Medical Society of Porto Rico was such at present that the society could not be admitted as a constituent of the American Medical Association, and it was therefore voted to defer such admission until the constitution of that society should have been amended to conform with the constitution and by-laws of the American Medical Association.

Resolutions of Thanks.—Resolutions were adopted expressing gratification and appreciation on the part of the members of the association to the various organizations and individuals who had contributed to the success and enjoyment of this meeting.

Place of Next Meeting.—Atlantic City was chosen as the place of the next meeting.

SECTION ON MEDICINE.

Wednesday, June 28—Second Day.

DR. WILLIAM A. JONES OF BUFFALO, CHAIRMAN.

Effects on Secondary Anemia by Hypodermic Injections.—Drs. WILLIAM JARVIS BARLOW and ROBERT L. CUNNINGHAM of Los Angeles, Cal., presented this communication, reporting upon three preparations used, iron cacodylate, sodium cacodylate, and arsacetin. Iron cacodylate was said to be iron in combination with cacodylic acid and therefore an organic form of iron and arsenic; sodium cacodylate contained sodium in combination with cacodylic acid; and arsacetin was an acetyl derivative of atoxyl said to be much less toxic and much more stable than that more familiar drug. Of each drug a single dose was contained in an ampoule and the preparation was sterile and ready for use. The injections had been made most commonly in the deltoid muscle. The injections had been employed on twenty-eight patients from which they concluded as follows: 1. When the hemoglobin content of the blood was relatively low, *i. e.* when the color index was very low, below 0.8, the dose of 0.03 grams might be given twice or three times a week, changing the site of injection each time. There was apparently more direct stimulating effect derived from the iron solution than from the others. 2. When the patient was not neurotic and would not object to the pain accompanying the administration of the solution, sodium cacodylate was to be preferred when there was any suspicion of syphilis and here they used one c.c. of the thirteen per cent. solution three times a week or at least twice a week; when a painless solution was particularly desired they used one cc. of the five per cent. solution twice a week as being safer than the stronger solution, when there was some degree of secondary anemia, but with a color index fairly high, as above 0.8. Arsacetin was to be preferred when it was to be combined with tuberculin treatment and when sodium

cacodylate was not well tolerated. In all cases they used 2 cc. of a ten per cent. solution and gave that amount two or three times a week, or even daily if it seemed desirable. Although they had seen no harmful effects from these drugs they had avoided their use during hemorrhage from the lungs, waiting at least one week after the sputum had cleared before resuming injections; during the so-called asthmatic attacks of the cases with a great deal of chronic bronchitis and emphysema, fearing to irritate the mucous membranes during such seizures; in all cases with marked albuminuria and cylinduria; and where there had been marked intereference with the circulation.

Reserve Renal Capacity in Chronic Interstitial Nephritis.—Dr. Edward F. Wells of Chicago said that in the midcourse of chronic interstitial nephritis with the secreting structures of the kidneys greatly reduced by degenerative and atrophic processes more or less marked renal insufficiency was the rule. Notwithstanding the difficulties and inaccuracies attending the estimation of the amount of urea, chlorides, phosphates and sulphates contained in the daily urine it was the opinion of the author that they were of sufficient diagnostic and prognostic importance to warrant their employment in routine practice. In many instances this insufficiency was very great, but in some instances material and even great reserve capacity might be discovered. In studing these cases attempts should be made to discover and measure the reserve, in addition to the ordinary functional capacity of the kidneys, for the purpose of strengthening the foundations of rational prognosis and treatment. In his own practice the writer advised such active and passive muscular exercises as might be taken without evidences of urea retention. The amount of proteid ingestion always small or moderate was gauged in like manner. These were points of great practical importance. Along similar lines estimations might be made of the capacity of the kidneys to eliminate urinary water and also chlorides. The latter taken in connection with observations upon the weight of the patient and of the extravascular tension, blood pressure, and cardiac hypertrophy was of prime importance and should be made with regularity. The main object of the paper was to stimulate further and more accurate investigation.

Pathological Findings in Hypertension.—Dr. Roger I. Lee of Boston read this paper in which he made a comparison of blood pressure determinations taken shortly before death and the pathological lesions found at autopsy. The material reported consisted of the pathological findings in every case showing a systolic blood pressure of over 160 in life which had come to autopsy from the medical wards of the Massachusetts General Hospital from January 1, 1907 to April, 1911. The pathological findings showed some kidney lesion in 71 per cent. of the cases; arteriosclerosis in 69 per cent., there being only one case of hypertension with arteriosclerosis in which there was no kidney lesion; cerebral lesions in 15 per cent. of the cases; cardiac lesions in over 24 per cent., these lesions being in addition to simple hypertrophy and dilatation; in 28 per cent. no kidney lesions were found. The following conclusions seemed justified: Hypertension occurred most commonly in association with some lesion of the kidney. The most common lesion was an atrophic kidney with increase of connective tissue and disappearance of glomeruli. Hypertesion occurred also in association with acute, subacute and chronic glomerulonephritis. Hypertension occurred not infrequently in association with cerebral lesions. A moderate degree of hypertension might occur in cardiac lesions. In valvular cardiac lesions the aortic valve was apparently always involved. Hypertension might occur apparently rarely in cases of general arteriosclerosis without other lesions. With a continued systolic blood pressure of over 200 some form of nephritis was found. Hypertension usually indicated well marked cardiac hypertrophy. The hypertrophy might be moderate in connection with a well marked hypertension over a considerable period.

New Clinical Values in the Treatment of the Gastric Neuroses.—Dr. Chas. Lyman Greene of St. Paul, Minn., said that the nervous dyspeptic had ever been a joy to the quack, the *bête noir* of the honest surgeon and internist, and a mystery to all three. He summarized as follows: (1) The gastric neurosis whether motor or secretory depended almost wholly upon an underlying asthenia. (2) This asthenia might be acquired, temporary and due to self starvation or other debilitating causes, but almost always presented a chronic congenital insufficiency of body structure and function, producing a peculiar nutritional instability. (3) That so-called passive neurasthenia or psychasthenia was most frequently seen in individuals of the asthenic habitus and was but a part of the clinical picture though a genuine and troublesome complication. (4) That gastroptosis produced symptoms only in the presence of atony of marked secretory changes and did not justify primary operative procedure. The same statement as to the unwisdom of operative interference applied to other displacements such as movable kidney and certain uterine malpositions. (5) That certain cases occurred in which no structural abnormality existed. That of these some were due to self starvation, others occurred in the robust individual who represented the "*malade imaginaire.*" (6) That under proper conditions the gastric neuroses of the common type justified hopeful prognosis. (7) That pain manifestations were so variable as to site, severity, character, and persistence as to lead frequently to erroneous diagnosis and futile operative interference, but that rational nonsurgical treatment afforded relief in the greater number of the cases. (8) That cases of the chronic congenital type bore surgery badly and usually obtained from it either definite harm or but slight and transient improvement. (9) That simple procedures might give great relief to mild cases and to those patients whose means would not permit the institution of the proper treatment, but that under the latter conditions failures were frequent. (10) That all severe or persistent cases demanded isolation, rest, and hypernutrition, combined with helpful suggestion and the minimal use of drugs. (11) That in their modern treatment of the dominant asthenic type of gastric neurosis they were successfully attacking that most common cause of chronic invalidism.

The Blood Pressure in Pneumonia.—Dr. Alexander Lambert of New York read this paper in which he gave the results of his observations on the blood pressure in 48 cases of pneumonia in adults, eight of these being broncho- and 40 lobar pneumonia. The ages had ranged from 13 to 78 years and were such cases as were found in general hospital service. Of 11 fatal cases in the series 10 were those who had used alcohol. In the mild case in which there did not seem to be much toxemia the disease did not seem to change the blood pressure in young adults from the average normal, i. e., 120 to 130; it remained normal throughout their attack. In some young adults whose pulse remained below 120 and the blood pressure above 105, while there was no change at the time of the crisis, it fell below 100 after convalescence had set in. In other patients of this class as soon as the crisis occurred and convalescence set in the pressure quickly and steadily rose to 120 or 130 mm. In no case did they see a sudden fall of pressure at the crisis. In some of the severe cases the blood pressure had been low, the pulse, temperature and respiration very high and this ratio had remained persistently throughout the disease. Dr. G. A. Gibson of Edinburgh had summed up his experience on this subject as follows: "When the arterial pressure expressed in millimeters of mercury does not fall below the pulse rate expressed in beats per minute, the fact may be taken as of excellent augury, while the

converse is equally true. That is, when the pulse rate per minute is higher than the pressure of the millimeters of mercury, the equilibrium of the circulation is seriously disturbed." The class of patients last referred to were those in which Gibson's rule was most noticeable. In the patients who recovered the pulse usually diminished in frequency before the blood pressure. In some few instances the reverse occurred. In other patients the temperature and pulse did not run very high and the blood pressure was very low; in these the ratio of Gibson's rule did not point to a bad prognosis. In some patients suffering from chronic nephritis the blood pressure remained above 150 mm, but was distinctly lowered by the pneumonia. Some of these patients recovered and some died. In those who recovered the blood pressure rose after the crisis; in others with nephritis the blood pressure had remained high, 180 to 200, and yet the patients died. The readings of the blood pressure gave no hint of the cardiac failure. It was interecting to note that 20 of the 48 cases showed Gibson's rule and of these six died. Of the 28 that did not show Gibson's rule five died. It was also interesting to note that among those who showed Gibson's rule not quite half were alcoholics, and among those who did not show it not quite three-fourths were addicted to alcohol. Patients who had arteriosclerosis and chronic nephritis were not apt to show Gibson's rule, but the danger of cardiac failure was none the less very great. The measurement of blood pressure would often decide the question whether they should look to the heart or the blood vessels to reestablish the equilibrium of the circulation. Unless they knew whether they were dealing with a vasomotor paralysis with a low tension pulse or a cardiac failure with a high tension pulse they could not use adrenalin intelligently; it was unquestionably poor judgment to use it on a patient whose blood pressure was already high and whose heart was struggling without sufficient reserve force against too great a strain. It was a grave question whether alcohol was advisable in pneumonia unless they knew whether the blood pressure was high or low. A knowledge of blood pressure in pneumonia would often be of assistance in judging of prognosis and treatment.

The Importance of the Quantitative Regulation of the Diet.—Drs. H. D. Arnold and R. C. Larrabee of Boston presented this paper. The regulation of the diet had hitherto been empirical and unscientific; it had been qualitative, not quantitative. Modern infant feeding had been attended by marked success because it had regulated quantitatively the three food stuffs, protein, fats and carbohydrates. The problem of the quatitative regulation of the complex diet of adults had been regarded as too difficult for general application in practice. However, sufficiently simple methods had been devised to make such regulation practicable.. It was important in diabetes, nephritis, gout, tuberculosis, obesity, malnutrition, all diseases of metabolism, and in many other conditions. They had used the diet chart prepared by Dr. Arnold for several years and had found that it simplified the problem a great deal, and made it feasible to do this work in private practice satisfactorily, when once the physician was conversant with the method of its use.

Dr. Wilder Tileston of New Haven, Conn., said that the quantitative regulation of the diet was of extreme importance in the treatment of all conditions of undernutrition. It was not difficult to regulate the diet if one would take the trouble to study certain tables which gave the nutritive value of foods. Tables could be obtained from the United States Department of Agriculture, Bulletin No. 28, for ten cents.

The Incidence of Serofibrinous Pleurisy and Empyema as Complications and Sequalæ of Pneumonia, with Remarks on the Medical Treatment of the Conditions.—Drs. James M. Anders and Arthur C. Morgan of Philadelphia presented this paper. In general, it might be authoritatively stated that serofibrinous pleurisy was of more frequent occurrence than empyema in lobar pneumonia, a dictum strongly supported by statistical inquiries. The statistical observations which formed the basis of their paper, embraced an examination of 68,982 clinical and post mortem records, from which they culled 2512 cases of pneumonia, and found that of these 1335 presented complications. In the 2512 cases of pneumonia, serofibrinous pleurisy occurred in 198 and empyema in 68.

Laboratory Diagnosis of Syphilis.—Dr. L. S. Schmitt of San Francisco, Cal., read this paper and offered the following conclusions: (1) Examination by the dark field condensor was the surest and most rapid method of determining the presence or absence of the treponema pallida. (2) The success with fresh specimens and smears depended largely on the care and manner used in making the preparations to be examined. (3) The early diagnosis of syphilis became more important on account of the advantage obtained in shortening the disease in many instances by the use of salvarsan. (4) Serum diagnosis of syphilis was of great value throughout the course of the disease after the infection became systemic. (5) The complement fixation reaction was of value in determining a syphilitic etiology and the effect of treatment. (6) In cases under treatment a negative complement fixation reaction was not of the same value as a positive one in determining the presence or absence of the disease. (7) In certain forms of parasyphilis a negative reaction did not entirely exclude the presence of syphilis. (8) In syphilis of the central nervous system the complement fixation reaction should be done with the cerebrospinal fluid as well as with the blood-serum. (9) Great care should be taken in selecting and making antigens used in the complement fixation reactions. The reaction was a quantitative one and the accuracy of results was dependent entirely upon the quantitative relation between the various reagents. (10) With properly selected antigens the Wassermann and Noguchi methods were equally reliable.

Visceral Syphilis.—Dr. Frank Billings of Chicago read this paper in which he considered tertiary syphilis of the liver, lungs, great blood vessels, heart and kidneys. Gumma of the liver and hepatitis syphilitica were of frequent occurrence in city patients. Intermittent fever with chills, enlarged, palpable, and tender liver, occasional jaundice, leucocytosis and moderate secondary anemia were usual symptoms. Rest would often bring about a symptomless, latent state. Recurrences might occur over many years. Gumma of the lung might be mistaken for tuberculosis. Syphilitic aortitis and arteritis of various types resulted in aneurysm, myocarditis, etc. Syphilitic nephritis was recognizable. The fact that salvarsan aggravated the morbid condition of a heart, blood vessel, or kidney disease prohibited its use in these conditions; however, this remedy was undoubtedly of great value in early syphilis and in syphilis with gummatous infiltration and ulceration. A maximum dose of salvarsan followed by mercury was of undoubted value. Dr. Billings doubted very much if salvarsan would give better results than the rational use of mercury and the iodides. Exceptions might occur in which salvarsan might prove a better remedy.

Observations on the Value of the Wassermann Reaction.—Dr. Albert Keidel of Baltimore read this paper which was based on 378 cases examined by the Wassermann test. There were 50 cases definitely nonspecific that gave 100 per cent. negative reactions. Of 71 cases with lesions of a doubtful nature and a negative history for syphilis, 24 per cent. were positive and 5 per cent. doubtful. Of cases with lesions of a doubful nature and an indefinite history of syphilis there were 61, 37.7 per cent. of which gave positive reactions and two doubful. Of cases with a

definite history of syphilis but no lesions there were 83, 25 per cent. of which were positive and 5 per cent. doubtful. Of cases with suspicious or manifest lesions and a definite history of syphilis there were 113, of which 82.3 per cent. were positive and 6 doubtful. A positive Wassermann reaction was for practical purposes conclusive evidence of syphilis. The test might be positive in certain nonsyphilitic conditions and the difficulty lay in the correct interpretation of the negative results, and might be met by careful attention to the technique, by using only the highest powdered preparations, skillfully made and accurately titrated. When the result was in doubt they need not hesitate to make repeated tests. By taking these precautions a negative Wassermann reaction while not of equal value with the positive result was almost as reliable.

Observations on the Value of Salvarsan.—Drs. JOHN T. GERAGHTY and ALBERT KEIDEL of Baltimore presented a report which was based upon a series of 70 cases. From their experience with this drug they were convinced that it was an important addition to the therapeutics of syphilis. In almost every case where visible lesions were present complete disappearance followed the injection, and marked improvement in the general condition of the patient was a constant feature. In all cases refractory to mercury the response to salvarsan had been prompt and striking. The drug was indispensable in the treatment of patients who did not tolerate mercury. They wanted particularly to emphasize the fact that the use of salvarsan had now passed beyond the experimental stage. The superior ability of salvarsan over mercury to rapidly kill the *Spirochæta pallida* in the tissues had been demonstrated beyond question, and salvarsan was therefore indicated in every case of syphilis when not specially contraindicated, even where it seemed advisable to supplement it with the subsequent use of mercury. From their experience they strongly advocated a vigorous course of mercury following the injection of salvarsan, continued for about six months and possibly then followed by another dose of salvarsan.

The Disadvantages Incident to the Administration of Salvarsan.—Dr. DOUGLAS W. MONTGOMERY of San Francisco, Cal., said that the necessity in the present state of our knowledge of not relying entirely upon salvarsan, but of also prescribing the other great specifics, mercury and iodide of potassium, was evident. As salvarsan must be introduced directly into the juices of the body either intramuscularly, subcutaneously or intravenously, its administration required skill and the greatest care, and even then, from the nature of the drug, its introduction might be followed by most disagreeable results. The occurrence of severe pain, of necrosis, of non-absorption and of sepsis when the drug was given intramuscularly or subcutaneously, and when necrosis occurred, the long endurance of the subsequent ulcer had also to be taken into account. The disadvantages incident to salvarsan when too slowly absorbed or not absorbed at all were evident. The care, time and expense associated with giving the drug intravenously were disadvantages. Disagreeable temperature reaction occurred occasionally in certain cases. There were dangers associated with the specific reaction caused by salvarsan when the lesion treated was situated in an organ of great dignity. It was necessary to have the patient under trained supervision during the first few hours after the injection.

The Adequate Treatment of Syphilis.—Dr. W. T. WOOTTON of Hot Springs, Ark., said that the inferior results from the treatment of syphilis in the past was due to improper and insufficient treatment and physicians were in a great measure responsible for this condition. To cure syphilis each and every spirochæta must be found and put to death. Metallic mercury was the safest and only agent that could do this alone when given to saturation. The inunction method was the only one by which saturation could be obtained. The number of spirochætæ killed was in direct and exact proportion to the completeness of the saturation. The iodides, per se, were not curative, but acted as overseer, keeping the mercury at work and giving it access to enclosed lesions. Salvarsan, as a *therapia sterilisans magna* was a failure; as an aid in the temporary eradication of active lesions it was a boon. The closest they could come to a *therapia sterilisans magna*, an ideal course, was through metallic mercury to complete saturation, and salvarsan in full doses intravenously at the height of saturation. Negative serum tests could not be depended upon; therefore the course should be repeated after a sufficient time had elapsed to ensure elimination of the previous course and for the system to have returned to the normal; otherwise there was danger of arteriosclerosis from the mercury. The treatment could be carried out anywhere, but probably to much greater advantage at a resort where the entire time could be given over to the treatment, *sans* business, friends, etc., plus elimination before, during and after. In spite of abuse and misuse metallic mercury stood today without a peer as a specific for the cure of syphilis.

Salvarsan.—Dr. E. G. BALLENGER of Atlanta, Ga., said he was convinced from his experience with "606" that it was a most valuable adjunct in the treatment of syphilis, and he believed that if properly administered and repeated at suitable times better cures of syphilis might be effected than heretofore. The micropathology clearly showed that not infrequently second and third injections became necessary in order to dissolve the wall nature had thrown up in her effort to limit the invasion. After this nidus of infection had been exposed to the circulating blood subsequent treatment might kill the remaining organisms. Dr. Ballenger greatly favored the intravenous method of injection and suggested a new method of inserting the needle into the vein. The plan advised was to pass a small trocar through the skin over the vein and then to introduce the needle into the vein through the canula. The number of patients requiring an incision would be lessened considerably by the adoption of this procedure. The apparatus also had a dilatation in the connecting glass tubes near the stop-cock. These bulbous portions acted as air traps and thus prevented the injection of air which by chance might have been left in the rubber tubes. The gravity apparatus was connected to a three way stop-cock so that a test could be made first with physiological salt solution, after which the "606" was allowed to enter. Two hundred and thirty injections had been administered without a mishap worse than pain at the site of the injection which occasionally occurred before the technique was perfected.

Dr. D. W. MONTGOMERY of San Francisco said that mercury was the drug in the treatment of syphilis, an agent that had been used for 400 years; it was the best means they had in the treatment of this disease. Salvarsan might have its place, but mercury still held its own. The iodides were not in any sense specifics. One could get a specific action upon the lesions, however, without the giving of mercury at all. That mercury was a poison was in his mind as clear as anything in therapeutics; it had been known to be a poison for centuries. The laudation of mercury as the great specific in syphilis still continued and he thought held good.

Dr. HOWARD FOX of New York called attention to the work done with salvarsan at the New York Skin and Cancer Hospital during the past eight months. Following the injection of this agent they had one case of herpes zoster. In 128 injections they had found no serious effects. In two cases a general toxic erythema which was followed by a high temperature lasting three days resulted. In five cases there occurred a local necrosis from the subcutaneous and the intramuscular injections. He did not agree with the gentleman who said that the intravenous procedure was a

difficult one; anyone with any experience could introduce the needle into the vein without difficulty. Aseptic precautions should be observed before beginning the operation. The use of the salt solution was unnecessary; sterilized distilled water answered the purpose. The gravity apparatus was more convenient than the original Schreiber's method. Among 69 intravenous injections in eight they had had follow small nodules; in six of these the nodules disappeared shortly after the injection.

Dr. W. J. Butler of Chicago said that the term "cure" had been used so much that he really wondered whether they all had the same ideas on the syphilitic question. When was syphilis cured? He did not know. He did not think that anyone present could answer that question. He did not think that they could saturate their patients with mercury for two or three years and then satisfy themselves that these patients were cured for all time. Why? Because they knew they were not cured. The external manifestations of syphilis were the least important as compared with the visceral syphilis which occur in later years. When were these patients cured of their syphilis? When they were dead. The possibility of recurrences was always present. Should they disregard the recent advances made in syphilitic control and treatment? By no means. When syphilis was active the reactions could be obtained in 98 or even 99 per cent. of the cases. When one did not get this reaction it showed that the syphilis was inactive. The syphilitic patient should never be without the care of the physician, even though the reaction was negative after three or four years' treatment; they should occasionally receive treatment to protect against possible recurrences.

Dr. C. F. Hoover of Cleveland, Ohio, reported the case of a patient, a student in the University of Austria, who was sent to Switzerland because of hemoptysis; he did not improve there and returned home and died. The autopsy revealed a pulmonary syphilis. Dr. Hoover said he had been on a sharp lookout for cases of pulmonary syphilis, but he had come across but two cases in which he was absolutely sure of the diagnosis. The symptoms under antisyphilitic treatment entirely disappeared. So far as fever was concerned, he thought they could get any variety; he recalled one instance in which the elevation of the temperature was very sharp, from 97 to 106 within two hours and then dropping to normal within three hours. A suppurative phlebitis was the diagnosis. Under antisyphilic treatment the patient made a good recovery.

Dr. Harry Reeves Olliver of San Francisco, Cal., reported the case of a young man who had been treated for tuberculosis of the lungs for six years. He had hemorrhages, but no tubercle bacilli were found. He was asked if he had ever had syphilis. He smiled and the doctor had revealed to him Hutchinson's teeth. The Wassermann reaction was positive. The patient was placed on mercury, but improvement did not occur until he was given salvarsan. He gained eighteen pounds in weight within three weeks, and since had had no hemorrhages. Dr. Oliver reported four cases of nephritis in which there were a large percentage of albumin, granular and hyaline casts, general anasarca, ascites, etc. Under the administration of mercury and salvarsan the patients all recovered.

Dr. William Litterer of Nashville, Tenn., said he had seen salvarsan used in five cases of pellagra and in three marked reactions were obtained. In these cases the Wassermann reaction was negative, both before and after the injections. In three the reaction was quite severe, the temperature going to 104. He used salvarsan on two cases of sarcoma and got only a slight reaction. He tried it on two cases of psoriasis and got a reaction in one. Just what caused that reaction he did not know. It might have been due to some idiosyncrasy.

Dr. George H. Aiken of Fresno, Cal., said he had been treating syphilis for over thirty years and felt somewhat humiliated in being told that he had not cured a single case. He had treated a young man for two years; his patient then married a healthy young woman, and they had a family of four. The children grew up healthy; they never developed any local or constitutional symptoms of syphilis and he had had them under his personal observation for over twenty years. Was it possible that they were syphilitic? He could not believe it.

Dr. John H. Graves of San Francisco, Cal., said that many men presented themselves for treatment of a recent attack of syphilis; they were, as a rule, young, careless, and inexperienced and called upon the physician but a few times. They were terrified when they learned that they had this disease. As soon as they found that there were no terrible consequences they passed from observation. That was the last the doctor saw of them. If every recent case of syphilis could receive a full dose of salvarsan and then given as many inunctions of mercury as possible some of these individuals might be cured in a short time. Even if they were not cured this procedure might save some innocent person from being infected.

Dr. William W. Graves of St. Louis, Mo., believed that no case of syphilis was ever cured. This sounded like very strong language, but he believed that he had reason to believe in this opinion. He called attention to the inadequacy of the therapeutic measures employed in the treatment of syphilis.

Dr. B. H. Orndorrf of Chicago related his experience with nearly 100 cases of syphilis in which intravenous injections of salvarsan were given; in each case the Wassermann reaction was positive. Three cases of leucemia were also treated with "606." The first was one of myeloid leucemia, with 450,000 white cells; no beneficial or deleterious effects resulted from the injection until three months after, when trouble occurred in the auditory apparatus; one month later this patient died; at the time of his death he was totally deaf. The second case was one of lympatic leucemia, with 600,000 white cells of the uninuclear type. Three weeks after the injection this patient died with slight auditory disturbances. The third case was one of the chronic lymphatic leucemia; the white cells were less than 200,000. The injection produced neither advantageous nor deleterious effects.

Major Percy M. Ashbum, U. S. A., reported the case of a man, sixty-four years old, who was taken ill in the Philippine Islands and who was treated for malaria. He had an intermittent temperature running as high as 103 F. He coughed and expectorated. Tuberculosis was excluded. He was sent home with the diagnosis of pulmonary mycosis. Later he was treated for rheumatism. He then had hemorrhages from the stomach, and blood appeared in the stools, and he suffered from an acute anemia. With the development of a loud heart murmur a diagnosis of septic endocarditis was made. An analysis of the gastric contents showed the constant absence of hydrochloric acid, and the constant presence of blood, and the condition was then diagnosticated as one of cancer of the stomach. He gave a history of stomach disturbance which extended over a period of three years. This man was the soul of honor and denied ever having had syphilis. The Wassermann reaction was positive. He was placed on inunctions of mercury, which cured his pulmonary mycosis, his cardiac disease, his gastric cancer, etc., all very promptly. The speaker later learned that the patient's wife had suffered from severe headaches during the past thirty years; in her the Wassermann was positive. When the patient learned that a diagnosis of syphilis had been made he was very indignant and refused to take treatment. However, he was given a tonic which contained mercury, and he made a good recovery.

Thursday, June 29—Third Day.

Treatment of Diabetes Mellitus.—Dr. A. J. Hodgson of Waukesha, Wis., read this paper. He stated that a very small percentage of cases of diabetes mellitus were caused by some severe preëxisting pathological condition, but that approximately 90 per cent. of the cases applying for treatment were due to errors of metabolism. The majority of cases were due to long continued gross errors in eating; oft repeated emotional excitement, the excessive use of starches or of alcohol, the gouty diathesis and heredity, sometimes associated with exophthalmic goiter, all seemed to play a part in the etiology of this disease. The quantity of food as well as the quality and manner of eating should be considered. In a disease that had been years in developing it was hopeless to expect a cure in a short time, and this should be made very plain to the patient. Codein and arsenic might have their use in a limited number of cases, but as a rule they should be left severely alone. They were not only useless in most cases but lessened the patient's chances of recovery. The drinking of plenty of mildly alkaline water was desirable. Olive oil and castor oil should be given in all cases in which there was constipation. The diabetic should be kept mentally indolent and physically active, but he should not be fatigued. Many of the so-called gluten flours contained from 40 to 75 per cent. of carbohydrate and consequently were worthless to the diabetic. The author had advised a starch-poor bread made from a flour consisting of unground poppy seed, ground nuts, eggs, flour or dried spinach, salt, and milk. These biscuits contained only 5 per cent. of carbohydrate. Carbohydrate should be restricted in the beginning to the limit of safety and added gradually in but one form until the point of tolerance had been reached. Successful treatment depended wholly upon the degree of control that the physician was able to exercise over his patient.

Bubonic Plague (with Special Reference to That of Ground Squirrel Origin).—Dr. George W. McCoy, United States Public Health and Marine Hospital Service, dealt exclusively with plague in man that had been derived from infection among ground squirrels in California. Nine cases, all having occurred during the past three years, were considered. All originated in the rural districts in vicinities where plague was prevailing among ground squirrels. Four of the cases occurred in squirred hunters who had handled animals within a week prior to the onset of the symptoms. The cases might be classified as severe acute, mild acute, and subacute or pyæmic. The onset was often marked by a chill followed by fever and headache. Epistaxis was common. Glandular swelling occurred either coincidently with or following the systemic reaction. Fever and general symptoms continued for about a week. No case of primary pneumonic or primary septicæmic plague of ground squirrel origin had been observed. Bacteriological diagnosis was made in every case by isolation and identification of the pest bacillus. Treatment was with anti-pest serum when practicable. The disease among the ground squirrel covered ten counties. Healthy squirrels from plague zones were relatively immune to laboratory inoculation. The mode of conveyance of infection was not definitely know, but the probabilities appeared to favor flea transmission. The chief menace was the danger of infection of rats of cities leading to an epidemic.

The Treatment of Intestinal Amebiasis.—Dr. W. E. Musgrave of Manila, P. I., read this paper. He stated that there was not only a natural tendency to recovery from this disease, but that such recovery actually took place in a considerable percentage of patients and was so complete as to leave little or no permanent scarring of the intestinal walls. More recent studies had shown that the types of ulcers varied considerably and several decidedly different lesions had been described. The author was becoming continually more certain that there was a definite amebic pathology in which there was no break in the continuity of the mucus membrane of the bowel. In discussing the therapeutic value of ipecac, Dr. Musgrave said that possibly the variation in the efficiency of different preparations of this drug were responsible for the divergent results obtained from its administration in dysentery. The difference among medical men in regard to the definition of the word dysentery might also be responsible for the different results reported. He concluded, however, that ipecac was a valuable drug in clinical dysentery of whatever etiology. In a small percentage of cases it did no good whatever. The author cited cases to illustrate the curative effect of the acute disease upon the more chronic one of the amebic infection. That this occurred was also borne out by autopsy studies. A patient with clinical dysentery demanded during such periods absolute rest in bed, a very restricted milk free diet, and measures for the control of intestinal peristalsis and for the relief of pain. Cases of the chronic or intermittent variety might last for years unless properly handled. For these the writer recommended a liberal diet and some form of occupation requiring both physical and mental activity in a moderate degree. Such treatment being contraindicated only during acute outbreaks. Proper support of nutrition was considered the first requisite. Only such medication was indicated as tended to improve the patient's general condition, and to meet special conditions as excessive fermentation, hyperchlorhydria. Local treatment by bowel irrigation either alone or combined with some other form of medication gave most satisfactory results. The knee-chest position was undoubtedly the best one for any form of medicated enema. From two to four litres of fluid might be used. Thymol, quinine, and silver nitrate had proved to be of greatest value in local treatment. The effect of mercury salts in the treatment of amebiasis deserved further investigation. The writer had had most encouraging results from the use of protoiodide of mercury in old sluggish diarrheal types of the disease. The drug was administered just as it would have been in syphilis. Over-treatment was a very common error. With proper care the prognosis of this disease was good.

Experimental Intestinal Obstruction—Report of Further Physiological, Cytological, and Chemical Studies.—Dr. J. W. Draper Maury of Rochester, Minn., read this paper. Two small series of fifteen dogs each had been prepared as follows: Under profound anesthesia in each case the duodenum had been sectioned and infolded just aboral to the major pancreatic duct. All animals were treated exactly alike as regards dressings, postoperative care, and free access to water. In one series each dog was given by mouth four times daily about 30 cc. of a watery suspension of mucous membrane scraped from the jejunum and ileum of healthy dogs. Approximately 400 cc. of water were added to the entire scrapings, and it was found that this suspension would keep on ice about five days. No effort at standardization was made, but it was early observed that immediate treatment seemed more important than the size of the dose or later treatment. One was tempted to speculate on the fate of the numerous colon bacilli thus transplanted to unusual regions from the terminal ileum. Dr. Maury drew the following conclusions: (1) Epithelial cells of the jejunum and ileum given by mouth to duodenally obstructed dogs prolonged life in a series of fifteen animals by about thirty-six hours over a similar series to which the mucosa was not given. (2) The average pulse rate of the treated dogs was thirty-three beats lower than that of the untreated. (3) The belief that they were dealing with a cytological product was strengthened by the trend of the charts. These showed that beneficial action occurred early, just as in the case of any successful treatment by anti-bodies. (4) The chemical determinations in one animal showed a normal nitrogen

metabolism after duodenal obstruction and suggested a decreased functional power of the liver in terms of glycuronic-camphor.

Some Obscure Conditions of the Digestive Tract as Studied by the Roentgen Ray.—Dr. G. R. SATTERLEE of New York City presented this communication. The observations were made in the Dispensary of the University and Bellevue Hospital Medical College, in the Edward N. Gibbs *x*-Ray Laboratory. After considering the anatomy of the gastrointestinal tract in normal cases the motility in normal and pathologic states and the size and position of the viscera in some abnormal conditions, the writer described the method that they had used in making these observations. For the average adult they administered 75 grams of bismuth subcarbonate, suspended in 500 cc. of fermented milk. This was swallowed on an empty stomach, without previous catharsis. The radiographs were made by exposures of from one-sixth of a second to one second. The first radiograph was taken in from ten to fifteen minutes after the ingestion of the bismuth; the second was taken one-half hour after the bismuth. Six or seven were taken successively at intervals of one, two, three, four, five, six, and sometimes seven or eight hours after the bismuth was taken. Other radiographs might be taken after twenty-four and thirty-one hours. In every case exposures were taken at twelve to twenty-four-hour intervals until the last trace of bismuth had left the intestinal tract. Dr. Satterlee's observations had been made on twenty-eight patients with several duplicates as controls and three hundred and eight plates had been studied. The following conclusions were drawn: (1) The length of time that the contents of the gastrointestinal tract first reached each division of the tract, and the time in which each division was completely emptied could be definitely determined in each individual by means of the bismuth Roentgen of ray test. (2) The normal activity of each part of the gastrointestinal track could be definitely established. (3) The food, immediately after ingestion, began to pass into the small intestines, and by the end of an hour at least one-quarter of the gastric contents was in the jejunum. (4) The stomach was emptied of 500 cc. of milk or soup in two and one-half to four hours. (5) The time to the cecum of this meal averaged two hours and varied from one to five hours; it was shorter in children. (6) The complete emptying of the colon consumed from twenty-four to forty-eight hours. (7) The complete emptying time of the small intestine after this meal was probably about six hours. (8) The bismuth Roentgen-ray test was harmless and practical. (9) The ordinary methods of medical treatment could be more intelligently applied with the improvement in diagnosis accomplished by this test. (10) The bismuth Roentgen-ray test should be employed before an operation for a chronic condition of the gastrointestinal tract was performed. Dr. Robert T. Morris agreed with the writer in this essential.

Infantilism in Pituitary Disease.—Dr. ALBION WALTER HEWLETT of Ann Arbor, Mich., said that it had been generally recognized that tumors in or near the pituitary gland might produce effects on the body growth and general metabolism which were quite distinct from those of acromegaly and gigantism. The symptoms presented might be divided into two classes: those due to the mechanical effects of the tumor, and those which seemed to be due to an altered internal secretion. To the former group belonged the headache, vomiting, and visual disturbances, the most characteristic of which, primary optic atrophy, and unilateral or bilateral temporal hemianopsia were due to direct pressure on the optic chiasm or nerves. To the latter group belonged the sexual disturbances (retarded sexual development, cessation of menses, etc.), the obesity, the stunted growth, and possibly the occasional diabetes insipidus. These were due, in part at least, to a diminished secretion of the anterior lobe of the gland. Dr. Hewlett reported in detail three cases. The first gave a history of brain tumor; the blindness was due to primary optic atrophy. There was retarded growth. There was also sexual infantilism and obesity, together with diabetes insipidus. The patient was a man twenty-seven years old. The second case reported was a man forty years old. Since the age of thirteen years he had had periodic attacks of headaches with vomiting. There was a mild sexual infantilism. He had an adolescent height and figure. There was a bitemporal hemianopsia with primary optic atrophy. There were bony changes in the region of the sella turcica. The third case was a man, fifty-two years old, who had a retarded sexual development. He had a small frame and a large sella turcica. Pictures of these patients were thrown upon the screen.

A Clinical Study of Mobility of the Heart.—Dr. DUDLEY FULTON of Los Angeles, Cal., gave the result of a study of 193 cases. Of this number 49 were apparently healthy; the remaining 144 were private patients or routine cases studied in his wards at the hospital. In studying the movability of the heart in different positions of the patient the absolute or superficial dullness was used and determined by feeble percussion. In determining the change of the apex beat in different postures the usual point of maximum intensity of the apex beat was ignored. The point of the heart coming in contact with the palpating finger farthest downward and to the left was considered as the true apex. The conclusions obtained were the result of a second examination, or were controlled by two examiners, so that a fair degree of accuracy might be assumed. One of the most striking facts observed was the discrepancy between the amount of displacement of the apex beat and that of the cardiac dullness in the change of the position of the patient. In the 193 cases there were nine in which there was a total displacement of the heart downward, the so-called cardioptosis of Rummo. In seven of these there were clinical signs of atheroma of the aorta. From this study the impression was that the determination of the movability of the heart was of considerable value in the differential diagnosis of cardiac dilatation, and that before assuming that the heart was dilated to the right or to the left the mobility of the heart should always be determined. Immobility or fixation of the heart should always arouse suspicion of adhesion of the pericardium to neighboring organs. There was probably no serious heart lesion diagnosticated less frequently clinically than pericarditis with adhesions.

Symposium on Poliomyelitis.

A joint meeting with the section on diseases of children was held.

Epidemiologic and Etiologic Studies of Acute Poliomyelitis in Pennsylvania.—Dr. SAMUEL G. DIXON, Commissioner of Health of Pennsylvania, presented this paper, which was read by Dr. Howard Karsner of Philadelphia. Pennsylvania's important research work in poliomyelitis and a detailed account of the department's epidemiological and clinical studies compiled from the records of many practising physicians throughout the commonwealth was the subject of this interesting paper. A graphic description of how the disease began in the Lehigh Valley and later in Lancaster County, and how it gradually spread throughout the entire Commonwealth until a total of 1067 cases were reported, illustrated by a map of the State and a diagram showing the ages of those afflicted, attracted a great deal of attention. A mortality of 240 cases for the year 1910 was very surprising to students of this disease who had been accustomed to a mortality nearer 10 per cent. than that found in Pennsylvania's serious epidemic. A full report of the department work in the field laboratories was given and a further report was made concerning the micro-

organism found in the blood of human cases of poliomyelitis, and experimental cases of this disease in monkeys. The only new feature regarding this research work was that recently the laboratory staff had demonstrated active motion of this microorganism and the further fact that it could be grown in blood bouillon, plain bouillon, and blood agar.

Recent History and Etiology of Infantile Paralysis—Pathology, Diagnosis, Prognosis, Prophylaxis and Treatment of Infantile Paralysis—Infantile Paralysis as Observed in Massachusetts, 1907-1910.—Drs. R. W. Lovett and M. W. Richardson of Boston presented this communication. They stated that infantile paralysis in the United States had increased very rapidly of late years. In the five-year period ending in 1904 about 1000 cases were reported, and in the year 1910 8700 cases were reported in the United States. The disease was a reportable one in twenty-three states. It had been proved to be infectious, and was evidently transmissible from person to person and by means of a third person. In addition to personal transmission one must consider the possibility of contracting it from fruit, dust, insects, and the domestic animals. The very great increase in travel in the United States was probably a factor in the more rapid spread of the disease of late years. It could be caused experimentally in monkeys, and in rabbits paralysis could be caused by inoculation of the human disease, which after being transmitted through several generations could be again transmitted to monkeys. Immunity was conferred by one attack. The disease was less transmissible and less common than measles, scarlet fever, etc. The account of the symptoms was given, calling attention to the frequency of cerebral types and their association with spinal types. Prevention must proceed upon general principles as in other infectious diseases, and quarantine and disinfection of secretions and premises were essential. About 16½ per cent. of the cases recovered inside of three months, and about 27 per cent. inside of four years. Treatment in the acute stage should consist of rest and the prevention of deformity. Apparatus and operative treatment were considered in their relation to the chronic stage. Two thousand one hundred and thirty-eight cases occurring in Massachusetts were analyzed in regard to various aspects of the disease. Where a limited locality had been severely affected one year it was practically immune in the following year. The death rate in Massachusetts had been 8 per cent., and the disease was more frequent in the smaller cities and towns than in the larger ones. The studies of the State Board of Health for four years were analyzed and various conclusions from them presented.

Election of Officers.—*Chairman*, Dr. Wilder Tileston of New Haven, Conn.; *Vice-Chairman*, Dr. W. L. Berring of Des Moines, Iowa; *Secretary*, Dr. Roger S. Morris of Missouri; *Orator*, Dr. Chas. L. Greene of St. Paul, Minn.; *Delegate*, Dr. J. A. Capp of Chicago; *Alternate Delegate*, Dr. S. W. S. Toms of Nyack, N. Y.

SECTION ON SURGERY.

Wednesday, June 28—Second Day.

Dr. George W. Crile, of Cleveland, in the Chair.

Oration on Surgery: Some Observations on Ascending and Hematogenous Infections of the Kidney.—Dr. George E. Brewer of New York described in detail animal experimentation to determine the factors in ascending and in hematogenous infections of the kidney. He stated that bacteria placed in a healthy bladder did not infect the kidney for two reasons, first, because of the descending flow of urine and, second, because of the valve-like action of the opening of the ureter in the bladder. He found that retention of urine in the bladder did not open the orifices, but that retention plus muscular contractions caused a reflex opening of the ureteral orifices and could force bacteria and inert substances into the pelvis of the kidney. The clinical conditions necessary for an ascending infection are, therefore, incomplete retention such as is associated with enlarged prostate or tenesmus from an acute cystitis. In experimenting with hematogenous infections great difficulty was experienced in determining the proper dosage of bacteria. Given a proper dose there was no infection of a healthy kidney, but if the kidney were subjected to trauma or to circulatory disturbances infection in that kidney took place. He concluded that hematogenous infections usually affected one kidney at first and that a damaged kidney was an element of danger in any individual.

The End-Results of Gall-Bladder Surgery.—Dr. E. MacDowell Stanton of Schenectady, N. Y., drew conclusions from 350 cases of gall-bladder disease. In cases of gallstones a permanent cure was obtained almost always when all the stones were removed. Overlooked stones being the cause of uncured cases, cholecystotomy was the operation of choice even when the gall-bladder was apparently functionless, provided all obstructions were removed. In cases of cholecystitis without stones the operative results were not brilliant, only about 50 per cent. of the cases being cured. This class of cases was often better treated by medicinal means.

Factors Hostile to Success in Gall-Bladder Surgery.—Dr. B. B. Davis of Omaha stated that there was often more pain after an operation on the gall-bladder than before, owing to suspension of the gall-bladder to the abdominal wall. Such suspension was not necessary if the ligature about the drainage tube was slight. All raw surfaces should be covered to prevent later painful adhesions. A fibrous gall-bladder without muscular tissue should be removed to prevent future stagnation. In cholangitis the drainage must be prolonged until the bile was clear. Patients should not be discharged immediately after healing was complete, but should be treated medicinally.

Dr. Robert T. Morris of New York stated that he had caused the closure of a mucous fistula from the gall-bladder where there was still functionating mucous membrane by the injection of Beck's paste. He stated that gallstones did not usually reform after removal because stones were formed in a single toxic attack which might not occur. In cholecystitis with adhesions but without stones he had had brilliant results and preferred to make a diagnosis of simple cholecystitis, admitting that stones might or might not be present. Many of the cases of apparently unsuccessful gall-bladder surgery, he stated, were due to an interstitial pancreatitis which was comparatively common.

Dr. A. J. Ochsner of Chicago stated that in many cases of gall-bladder disease there was associated an intestinal intoxication due to stasis. He advised against operating in the acute attack. In cases of apparent pyloric obtruction associated with gall-bladder disease the stomach symptoms were due to obstruction in the duodenum at the ampulla and subsided after operation on the gall-bladder.

Dr. J. F. Percy of Galesburg, Ill., stated that pancreatic disease had still many points to be worked out in connection with these cases.

Dr. F. L. Hupp of Wheeling, W. Va., reported a case of transposition of the gall-bladder. An incision was made in the usual place, but no gall-bladder was found. The incision was then carried across the median line and the gall-bladder was found on the left side.

A New Technique for Rectopexy for Rectal Prolapse.—Dr. L. L. McArthur of Chicago described a new technique for cases in which the simpler methods were ineffectual. It consisted in an anastomosis between the anterior rectal wall and the fixed end of the sigmoid and colon. The rectum was suspended to the fixed colon.

Dr. Andrews of Chicago stated that the above operation was the one best suited to the condition because it fixed a movable organ, the rectum, to another movable organ, the sigmoid, instead of to the immovable abdominal wall, thereby obviating much pain from traction.

Lingual Thyroids.—Dr. C. H. Mayo of Rochester, Minn., spoke of the development of the thyroid and of thyroglossal cysts. Sublingual or lingual thyroids might be due to delayed descent of the thyroid gland. The aberrant thyroids might be due to traction by the thymus. The condition must be differentiated from simple lingual tumors, malignant tumors, thyroglossal cysts, and lingual tonsils. The diagnosis was usually made at operation. The technique of the operation consisted in firm traction on the tongue by suture. It might be necessary to do a laryngotomy. Hemorrhage was controlled by deep sutures. He reported 50 cases with no fatalities.

Megalocolon.—Dr. W. I. Terry of San Francisco stated that colopexy and coloplasty were of little use as a rule. Resection of the dilated colon was usually best. He reported two cases. Colostomy should be done first. Of 110 cases, 82 recovered and 28 died.

Mr. Howard Stiles of Edinburgh said that this condition was relatively common in children. There would be a history of partial obstruction for two or three weeks, then the discharges would be more copious, with colicky pains. He reported a case of a boy of 8 years in whom he did a permanent colostomy through the vermiform appendix with recovery.

Treatment of Tuberculosis of the Long Bones.—Mr. Howard Stiles of Edinburgh showed many *x*-ray plates of tuberculosis of the shaft of the long bones, both before and after treatment. He treated the cases by subperiostial resection before the periosteum became diseased. In all cases the bone was regenerated.

Gonorrheal Osteoperiostitis of the Diaphysis of the Femur.—Dr. S. H. Watts of Charlottesville, Va., reported a case with history of gonorrhea of several weeks' duration. The thigh was swollen. On operation the periosteum was found thickened and beneath it was a turbid fluid which contained gonococci. The medullary cavity was not opened. The *x*-ray showed the shaft thickened by newly formed periosteal bone. The condition was first reported by Fournier in 1869. Some observers claimed the inflammation was outside the periosteum, but the speaker's cases seemed to be instances of osteoperiostitis.

Tendon and Fascia Transplantation.—Dr. D. D. Lewis of Chicago stated that tendon and fascia could be interchanged because structurally the two tissues were not widely differentiated. Cases were cited in which tendons had been transplanted from one fowl to another and from dog to man. Personal experiments were made on dogs with perfect functional results. The transplants became larger than normal. The fascia lata had been used as a substitute for tendon. Pictures were shown illustrating a case of a boy in whom the tendon of the trapezius was transplanted to the deltoid with the interposition of a piece of fascia lata. The result showed abduction of the arm to about 70°. This abduction had since increased.

Dr. L. W. Ely of Denver cited an instance of transplanting the fascia lata to a defect in the dura mater.

Dr. McKenzie of Oregon asked for instances of fascia being used to fill the gaps in nerves with restoration of function.

Treatment of Joint Tuberculosis.—Dr. Leonard W. Ely of Denver stated that the great variety of methods of treatment of joint tuberculosis showed that the treatment of this disease was unsatisfactory. He formulated the following rules: (1) Treatment should be radical. A few milder synovial forms might recover by conservative treatment, but were likely to recur. As diagnosis was difficult such cases as recovered might have been mistaken diagnoses. Cases treated radically did not recur. (2) Operation should deprive the joint of function. Synovia and red marrow were most susceptible, therefore one should destroy the function since such procedure destroyed these tissues. (3) The operator should avoid secondary infection by removing the drains early. Rule No. 1 presumed that lymphoid cells were not phagocytic but were the most susceptible prey of the bacillus.

Dr. J. B. Murphy of Chicago complimented Mr. Stiles on his results, but his own experience was almost diametrically opposite, since it had been with adults, while Mr. Stiles's had been with children. In children the condition began in the diaphysis, whereas in adults it began in the epiphysis, and the joints were likely, therefore, to be involved. In operating it was not necessary to preserve periosteum, as Mr. Stiles advised. Ambulatory treatment of a diseased joint was a mistake; it should be immobilized.

Dr. S. F. Huntington was not satisfied with the treatmen of hip-joint disease now in vogue. One should tunnel through the subtrochanteric route up to the epiphysis and clean out thoroughly and let it heal, using Beck's paste if necessary. This was different from general surgical principles.

Mr. Stiles said one must remove disease in a synovial membrane. It began in the epiphysis in adults because the nutrient arteries were longer; this was not so in children. It was more common in the elbow in children for the same reason.

Dr. Ely said it was not necessary to remove the synovia because when the function of the joint was destroyed, the synovia disappeared. It was impossible to remove the synovia with the curet, as advised by Dr. Huntington. This method destroyed the nourishment of the cartilage and caused the disease to open into the joint.

Treatment of Localized Appendicular Abscess.—Dr. Van Buren Knott of Sioux City, Iowa, advocated always removing the appendix in localized abscess. He made his incision through the right rectus muscle, walled off the general cavity and separated all adhesions, thereby opening all pockets of pus and removing the appendix. He did not fear spreading the infection because a localized peritonitis could be so well controlled by the Fowler position.

Dr. Huntington of San Francisco did not agree with Dr. Knott. In certain cases he did not remove the appendix at the primary operation but merely drained.

Dr. A. J. Ochsner of Chicago said he removed the appendix in nearly all cases, but when in doubt as to the recovery of the patient he merely drained and left the wound entirely open. His patients were kept on liquids until the appendix was removed.

Dr. Knott, in closing, stated that by removing the appendix in every case the mortality was reduced from 8 per cent. to 1 per cent.

Thursday, June 29—Third Day.

Spinal Fractures.—Dr. A. F. Jonas of Omaha said that the osseous lesion was no index to the extent of cord destruction. Exploratory laminectomy should be done immediately, as near as possible to the seat of the fracture. All motion and jarring, as in transportation, should be avoided lest the injury be increased. Delays were dangerous, as degeneration might ensue. Dr. Jonas cited several cases illustrating these points.

Dr. H. W. Howard of Louisiana emphasized the importance of early operation. He stated that the best results followed cases of compression only, but that regeneration of the cord might occur. He advised exploratory operation with opening of the dura. He presented a pa-

tient with a history of fracture of the 5th and 6th cervical vertebrae, with fragments of broken bodies projecting into the cord. The accident occurred in 1904. Paralysis, bedsores and loss of control of the asphincters followed. Laminectomy was performed April 15, 1911. The dura was found adherent. The adhesions were broken up and projections of the bodies of the vertebrae chiseled off. The patient now had control of the sphincters, was able to sit up and move his arms and to some extent his legs.

Dr. STILLMAN of San Francisco stated that in his experience no improvement followed operation. Hope of regeneration of cord was practically nil. Operations had, however, done no harm and the patients recovered from operation.

Dr. THOMAS of Los Angeles stated that his results had been the same as those of Dr. Stillman. The cord never regenerated. Cases that were relieved, he believed, were due to hemorrhage. He continued to operate, but believed the outlook was hopeless.

Dr. STRONG of San Bernardino complimented Dr. Jonas on his results. He reported four cases, one of which recovered, the other three dying of septicemia. The successful case had a fracture of the lower dorsal vertebrae with complete division of the cord. The cord was united by sutures, care being taken to preserve the posterior root ganglia. Recovery took place to the extent that the patient could now use crutches.

Dr. HARVEY CUSHING of Baltimore advised a study of the case by a neurologist before operation, so that the lesion might be more accurately located. He divided such injuries into three groups: viz., (1) Hematomylia. These cases recovered without operation which might do harm. (2) Total transverse lesion of cord. (This and the above condition might be diagnosticated.) Operation should not be done, as it was hopeless. (3) Other cases in which exploratory operation was advisable and might do good. He stated that in these cases, suprapubic cystostomy and drainage should be done to avoid bladder and kidney infection and bed sores from dribbling of urine. He emphasized the delicacy of the operation of laminectomy. The dura should be opened without injuring the arachnoid. The periosteum should be preserved.

Dr. JONAS, in closing, stated that help of the neurologist is frequently unobtainable. The operation did no harm. All his patients with complete transverse lesions died. The cord was difficult to suture. His cases of hemorrhage into the cord itself died.

Several Unusual Joint Cases: Their Treatment and the Results.—Dr. GEO. W. GUTHRIE of Wilkes-Barre, Pa., reported cases as follows: (1) Opening of elbow joint with separation of olecranon; nailed; result perfect. (2) Compound supracondyloid fracture of the elbow. Parts put into opposition and arm flexed strongly and secured to side by adhesive plaster. Passive motion at end of fourth week. Complete functional and cosmetic result. (3) Injury to tibia in which three-quarters of an inch of the upper extremity were severed by a hatchet opening knee joint. Fragment nailed. Parts sutured with catgut and plaster cast applied. Nails cut at end of second week. Perfect functional result. (4) Ankylosis of both knees in semiflexed position. Arthrodesis performed. L. knee now fixed with 10° flexion and R. knee had 10° motion. Patient walked upright, but cosmetic result was bad. (5) Compound fracture and dislocation of wrist: apposition secured and maintained by nails and cast. The result was perfect.

Dr. SHERMAN of San Francisco referred to Mr. Stiles' paper of yesterday. Hip-joint tuberculosis originated in the epiphysis when bone was growing. In the hip and elbow it was intraarticular and in other joints extraarticular. This could be explained only by Dr. Ely's hypothesis. Hyperplastic periostitis was rare. There was a tendency to early invasion of joint, especially hip. Operation was becoming more popular. Entire recovery without operation was not likely to occur.

Dr. HUNKIN of San Francisco did not believe in the efficiency of destruction of function of the joint in the treatment of tuberculosis nor did he believe that tuberculosis was found only in red bone marrow and synovia, as Dr. Ely had suggested. He approved of Mr. Stiles' treatment.

Thirty Years' Experience with Fractures at Minnequa Hospital—Treatment and Results.—Dr. R. W. CORWIN of Pueblo, Colo., suggested plaster of Paris casts for fractures before arrival at hospital. The top might be cut off and be refastened into place by straps. Scalp wounds and contusions should be explored thoroughly. In cases of fractures of the spine one should immobilize at once. When in doubt he explored, but not if the cord was completely severed, as such cases were hopeless. Early operation was best. Careful after-treatment was necessary. More of his patients were living after non-operative treatment. One should avoid plating of bone when there was insufficient covering of soft parts. Early plating was best as not so likely to become loose. It was imperative to use non-irritative material for plates. The first dressing of a compound fracture was important. One should not close without drainage.

Pinning Fractures Through a Cannula with the Aid of the Fluoroscopic Screen.—Dr. ROBERT T. MORRIS of New York in this paper said the trocar and cannula should be carried to the site of the fracture and by the aid of the fluoroscope the tractor was thus withdrawn and followed by a drill, and the drill followed by a silver pin which was driven into place by a tamper. Splints were applied in addition. It might be necessary to use extension before trying this method. Delay was also of aid in inducing leucocytosis.

Clinical and Experimental Work to Determine the Value of Lane's Plates in Treatment of Fractures.—Drs. WILLIAM BARTLETT and W. R. HEWITT of St. Louis read this paper. Clean screws would always hold in bone at least 71 days. In experiments on dogs he found that an average pull of 95 pounds were required to dislodge a ½-inch screw from dog bone with two mm. cortex. If the screw was infected only 41 pounds were required. Absorption of bone cortex and thickening of periosteum occurred around infected screws. Clean screws showed no change even microscopically. Clean screws were harder to withdraw after 60 days than at first. Human bones were harder, with thicker cortex, and longer screws were used and more screws. Splints should also be applied in these cases. The authors cited cases of compound fractures in man in which plates were applied. The mortality was 3.84 per cent. He discussed the advisability of open or closed method. The open method was necessary if good apposition could not be obtained otherwise: if the patient was in good condition an operation was risky. X-ray pictures were not always reliable. He illustrated the paper with stereoscopic views, showing (1) a winch to make traction to secure apposition of ends; (2) embracers to line up the fragments before releasing the winch; (3) drill press and other instruments for applying plates; (4) screw threaded all the way to the head; (5) plates.

Open Treatment of Fractures.—Dr. EDWARD MARTIN of Philadelphia emphasized the importance of early operation. He exhibited apparatus for securing apposition of the ends of the bone. Plates should be stronger. He inserted the screws as far as the medulla and not nearer than ¼ inch of the fracture. External splints were necessary. The less foreign matter there was in the wound the better. He showed stereoscopic pictures on the screen illustrating cases and results.

Dr. BROWN of Santa Barbara exhibited a double flexible steel clamp fitting snugly to the bone for the treatment

of these cases. It was adjusted by screw adjuster and projected only 3-32 inch above the surface of the bone when applied.

Dr. Pearse of Kansas City advised early operation, as screws held better. He emphasized the value of cleanliness. Iodine did not give enough antisepsis. The usual plates were too weak. He recommended a double T-plate which was folded around the ends of the fragments and screwed with six screws. External splints were applied. He advised proving out Lane's technique before trying to improve it.

Dr. Lund of Boston commended Lane's plates and similar methods. It was necessary to study Lane's technique. He commended traction apparatus. A case was illustrated with the stereoscope.

Dr. Wills of Los Angeles recommended a double plate with through and through screws. He exhibited a case with perfect functional result.

Dr. Fuller of Chicago advised non-operative treatment if possible. He commended Drs. Bartlett and Martin, but thought traction apparatus could be dispensed with. It might have a place, however. He emphasized the danger of infection and therefore was afraid of instruments which had been exhibited because of trauma. After operation he placed the limb in splints and suspended it as high as possible.

Dr. Mitchell of Washington suggested local anesthesia if unnecessary to wound the medulla. Otherwise one should use nitrous oxide.

Dr. Rogers of New York advised a complete set of Lane's instruments so that the fringes might be kept out of the wound and infection avoided.

Dr. Warner of Ohio, after plating or wiring, treated just as the closed method to prevent traction of the muscles. Splints should be opened to expose the wound.

A Theory for the Pathological Physiology Involved in Diseases of the Thyroid Gland and Its Therapeutic Application.—Dr. John Rogers of New York said that thyroid functions were only to produce secretion. They had to do with oxidation, carbohydrate and nitrogen metabolism. The thyroid was normally like a sponge. In Graves' disease it was more solid and contained less iodine. The injection of nucleoproteid produced tachycardria, nervous tremor, sense of heat and unrest. It stimulated the sympathetic system. Globulin caused in normal man a feeling of well-being. It was a diaphoretic, diuretic, chalogogue, and a tonic. It was almost a specific for gout in its early forms. In Graves' disease resulting from fatigue the thyroid was enlarged to help out the organs in activating secretion. There was an excess of nucleoproteid and a deficiency of globulin in the fatigued gland. The normal human thyroid histologically contained comparatively a small amount of epithelium and a large amount of calloid; when pulpified and suspended in salt solution it yielded a small nucleoproteid precipitate and a large globulin precipitate. The thyroid of acute toxic Graves' disease showed the reverse of both conditions. The two substances could not be entirely separated but possessed distinct physiological properties. The clinical evidence was overwhelming that fatigue was the exciting cause of Graves' disease. The clinical evidence in untreated patients and the persistence of certain symptoms after thyroidectomy indicated participation of other organs than the thyroid in the original fatigue. The therapeutic problem did not involve rest alone. The treatment was rest and iodine feeding or rest supplemented by organotherapy, as indicated.

Factors Influencing the Safety of Surgical Treatment for Goiter.—Dr. Martin B. Tinker of Ithaca, N. Y., said that the surgical treatment had stood the test better than the medical. The importance of thorough physical examination was emphasized. The internist, surgeon, and laboratory man should compare findings in any given case. As regards anesthesia, various forms were used, but some cases required local anesthesia. If general anesthesia was employed the patient has to be only partly under its influence. Angulation and compression of the trachea might cause death. Rise in blood pressure caused profuse hemorrhage. The speaker preferred local anesthesia. Nitrous oxide was the safest general anesthetic, and was best used in conjunction with local anesthesia. The wound healing was important, as there was little resistance to infection. He did not use iodine, as too much was in circulation already. Harrington's solution was discarded. Skilled assistance was necessary. Team work was important in operating. The results of the speaker's work in this field were 167 operations without loss of life. The risks were slight and mostly accidental.

Dr. Ochsner of Chicago said that Dr. Rogers' work brought out the meaning of hyperthyroidism. Heretofore hygienic and dietetic measures and ligation were the main principles in the treatment. Later removal of part of the secreting gland was considered the proper procedure. Local anesthesia was advisable, since the patient was awake, and no traumatism was used. The speaker used morphine and atropine before operation.

Dr. Rogers emphasized the worthlessness of commercial thyroid. He did not use ether, but used nitrous oxide and local anesthesia.

Dr. Tinker said that local anesthesia in the hands of those with surgical experience should be tried and compared with general anesthesia.

Lymphangiomata of the Omentum and Omental Cysts.—Dr. Stanley Stillman of San Francisco said that cysts had their origin in the lymph vessels of the omentum. He reported cases. There were cyst cavities separated only by a thin wall from the blood vessels, which were dilated over them. The etiology showed these cysts were either lymph spaces dilated, or endotheliomata or congenital structures.

Tumors of the Mesentery.—Dr. H. A. Royster of Raleigh, N. C., said that these tumors were rare, but important. Text books gave an inadequate description of these structures. The difficulty in treatment was due to the fact that they were partly of embryological development. They were mesoblastic in type, and the cystic tumors were more common. As regards their etiology, many were congenital. Trauma also played a rôle. The speaker cited a case where trauma lighted up previously existing ones. He reported four personal cases: (1) A dermoid cyst of the mesocolon. The appendix was adherent to it. This was rare, and of congenital origin. (2) Sarcoma of sigmoid mesocolon. The patient died from cachexia, after the operation. (3) Sarcoma of the mesocolon. The diagnosis was impossible. Exploratory operation was necessary. Pain, constipation, nausea, and vomiting indicated intestinal occlusion. The tumor was characterized by free mobility, especially from side to side. It was separable from the solid viscera. There was resonance above and below, and colicky pain in the region of the umbilicus.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

Wednesday, June 28—Second Day.

DR. H. G. WETHERILL OF DENVER IN THE CHAIR.

The Value of Pyelography.—Dr. W. F. Braasch of Rochester, Minn., read this paper, in which he discussed the limitations of cystoscopy and advocated the injection of an opaque solution into the ureters and pelvis of the kidney, with immediate radiography. The method was not dangerous and had great value in demonstrating the extent and character of renal and ureteral dilatations, calculi, deformities, and congenital anomalies. Most radiographs

required additional data to be of value, and these were obtained by pyelography. The paper was concluded with a demonstration of radiographs obtained by this method, showing cases of dilatation of the ureter and pelvis of the kidney, renal calculi, renal tuberculosis, and some congenital anomalies.

Dr. H. G. Wetherill of Denver suggested that an outline of technique would be of interest to the section.

Dr. Braasch used a freshly prepared 10 per cent. solution of collargol, usually 5 cubic centimeters being sufficient. Pain was usually due to overdistention of the ureter and pelvis of the kidney. A radiograph was taken immediately after injection, usually a 5 or 6 second exposure being made.

Dr. E. E. Montgomery of Philadelphia said that this opened up a new field in the diagnosis and treatment of diseases of the kidney and ureter and greatly reduced the liability of making mistakes in diagnosis and subsequent operation.

Dr. Wetherill also emphasized the importance of the paper and expressed great appreciation to Dr. Braasch for his contribution and demonstration of slides.

Postoperative Urinary Retention and Cystitis.—Drs. J. H. Jacobson and J. G. Keller of Toledo, Ohio, presented this paper, which was read by Dr. Jacobson. They said that postoperative cystitis was more common than would be supposed, often spoiling an otherwise good surgical result. The cystitis was not always due to the catheter, since it was often found in cases where no catheter had been used, but the catheter was nevertheless the most important single factor on account of the injuries inflicted by it on the mucosa. The most common predisposing causes were retention, trauma, and congestion. The most commonly found microorganism was the colon bacillus, which was found in the lower urethra after the recumbent position had been assumed for a few days. Good results had been obtained by using "Frank's bladder laxative," consisting of a 2 per cent. solution of boroglyceride, which irritated the bladder mucosa sufficiently to cause voluntary micturition. From ten to fifteen cubic centimeters of this solution were injected with the urethral syringe, since this instrument did not cause the trauma which a catheter would. Following the paper was a demonstration of slides made by Dr. Keller, showing the pathological appearance of the bladder after various operations.

Pericystitis.—Dr. M. L. Harris of Chicago read this paper, in which he stated that the causes of pericystitis were either direct injury or extension of inflammation from adjacent organs. He cited a case in which a pus-tube was found lying between the uterus and the bladder and draining into the latter. The pus then passed by an extraperitoneal tract down the thigh. These bladder lesions were mostly postoperative, usually from lack of care. The bladder was often involved in suturing other parts. The author cited a case in which part of the bladder was caught under the round ligament where it was shortened, and he urged greater care in pelvic work.

Dr. E. E. Montgomery of Philadelphia said that in the earlier work lack of care caused much suffering from cystitis. Pericystitis was frequent in plevic inflammations of various kinds, causing severe adhesions.

Dr. W. R. P. Clark of San Francisco found that he could avoid adhesions by allowing the patients to change their position in bed continually.

Dr. W. B. Dorsett used great care in hysterectomies to hold the stump in its normal position by the use of the broad and round ligaments so as not to distort the relations of the bladder to other pelvic viscera.

Dr. A. E. Benjamin of Minneapolis said that patients often complained that the resulting cystitis was worse than the original operation. Improper technique was often the cause. He cited cases in which the appendix was found adherent to the bladder, giving symptoms of cystitis rather than those of appendicitis. He had similarly found cystitis following adhesions of the tubes or sigmoid.

Dr. J. B. Frankenheimer of San Francisco said that the horizontal position in bed made it difficult for patients to urinate. He advocated training patients to use the bedpan before operations or deliveries.

Dr. Jacobson, in closing, urged the cystoscopic examinations as a control, so that the operator might estimate the trauma following the operation, even if there were no symptoms of cystitis.

Dr. Harris, in closing, urged great care, especially in round ligament work. It was easy to draw part of the bladder into the wound in which the operator anchored the broad ligament. He urged the making of incisions sufficiently large to avoid this complication.

Chairman's Address: Retrospection and Introspection; Our Opportunities and Obligations.—Dr. H. G. Wetherill of Denver began his address by reviewing the improvements in gynecology and obstetrics in the last decade. Puerperal sepsis had decreased with an increase in asepsis on the part of the general practitioner. He made a plea for conscientious surgical efforts; this necessitated better training and a higher standard of personal integrity in young surgeons. He spoke at length of the evils of the open hospital and suggested a board of physicians to control the privileges of the hospital, investigating the fitness of men who desired to do the major work. Hospitals, especially religious ones, should not allow professional abortionists to operate in them. Commercialism allowed hospitals to do these things, but we could do much by not tolerating these men in our societies or meeting them on the rostrum or in consultation. He suggested that the name of the section be changed to Obstetrics, Gynecology, and Abdominal Surgery. He argued that we could not always be sure of the diagnosis and therefore must be prepared in any laparotomy to do anything in the abdomen or pelvis.

A vote of thanks was tendered the retiring Chairman, Dr. Wetherill, by the Section. Dr. Wetherill moved that the question of change of name be referred to a committee, to report at a later time. The motion was seconded and carried.

Pathological Kinks and Adhesions in the Terminal Portions of the Ileum.—Dr. Franklin H. Martin of Chicago began by stating that the duodenum, appendix, sigmoid, and end of the ileum were most likely to be distorted. He said that Lane's kink accounted for many cases of uncured appendicitis and described the technique of operation. After operation the patient should be kept in bed, adjusted to a fifteen degree Trendelenburg position, while forced feeding should be practised. Gymnastic exercises were resorted to in order to strengthen the abdominal muscles. Belts were applied at once and were worn for some time. He finished his paper by showing slides illustrating his various methods of treatment.

Dr. W. B. Dorsett of St. Louis instructed his patients after laparotomies to move about freely to prevent the reunion of newly separated adhesions.

Dr. Arthur E. Hertzler of Kansas City, Mo., said that this condition was described fifty years ago under the name of sclerosis mesenterica. A fibrinous exudate formed between layers of the mesentery; when it became organized as fibrous tissue, it contracted and formed the shortened mesentery. He suggested that the operator caused this inflammation of the mesentery by trauma when he did an appendectomy, and so produced the resulting kink.

Dr. Hershey of Detroit did not believe in stitching the mesentery of the cecum to the parietal peritoneum. He simply shortened the mesentry by making a longitudinal incision and swing up transversely.

Dr. Chas. E. Barnett of Fort Wayne asked if the Tren-

delenburg position had interfered with the function of the kidneys. He did not believe that the introduction of oil into the peritoneal cavity prevented adhesions.

Dr. MARTIN, in closing, repeated the reasons why his method most closely imitated nature.

Personal Observations in the Treatment of 140 Consecutive Cases of Uterine Myoma.—Dr. WALTER B. DORSETT of St. Louis began this paper by giving the indications for the surgical treatment of myomata. He always urged operation on account of danger of malignant changes. Statistics founded on his cases showed a predominance of this condition between 40 and 50 years in nullipara. Hysterectomy was the operation of choice in these cases. He advocated ligation of large vessels as usual, with the addition of secondary stitches in adjacent tissues to prevent retraction and secondary hemorrhage. He demonstrated slides showing his technique.

Dr. GOLDSPOHN of Chicago spoke of the necessity of leaving at least part of one ovary to prevent premature menopause. He believed that the tubes should always be removed, as well as the cervix on account of danger of malignancy.

Dr. J. O. POLAK of Brooklyn reported a series of 132 cases. He believed that myomectomy tended to incite a recurrence of tumors. When he left the ovary he also left the tube in order to preserve the circulation. He urged firm fixation of the stump to prevent prolapse of the vagina. In high amputations he removed the mucosa of the cervix.

Dr. DORSETT, in closing, said that in operations for fibroids he always removed the ovaries in women at the menopause especially when they were diseased. He left the cervix unless there was a suspicion of malignancy.

Delayed Chloroform Toxemia.—Mr. HAROLD STILES of Edinburgh spoke of the pioneer work done by Leonard Guthrie of London, who wrote on this subject in the early 80's. He described many typical cases, concluding that the condition was more common in septic conditions, consequently many deaths attributed to septicemia were found to be due to chloroform narcosis. He believed that the brilliant results in septic appendicitis operations ten years ago in America were due to the use of ether, chloroform at that time being used in Great Britain with poor results. An extremely rapid fatty degeneration of the liver was followed by a degeneration of the mucosa of the stomach, bowels, kidneys, and meninges.

Dr. GRANT of Denver asked what evidence there was other than clinical to prove that chloroform had caused the reported deaths.

Mr. STILES cited the experiments on animals, and said that enough cases had come to autopsy to prove the point. He especially cautioned against the use of chloroform in children with acetonemia, in whom fatty changes already existed.

The Surgical Treatment of Ptosis of Abdominal Organs by the Hammock Operation.—Dr. R. C. COFFEY of Portland, Ore., read this paper. He discussed the anatomy and embryology of the intestinal tract. In Glenard's disease we had a change in connective tissue causing sagging of all the viscera with no kinks. In surgical ptosis we had a relaxation between definite fixed points in the gastrointestinal tract, forming kinks and causing stasis, with resulting symptoms. He said that we should not operate for anatomical displacement unless symptoms were present. Short-circuiting the bowel was often ineffectual, but the hammock operation had proven successful in all of his cases in which it was indicated. In extreme ptosis of the stomach and liver these organs must first be anchored, and then the shape of the abdomen must be changed by operation. The hammock operation consisted in suturing the gastrocolic ligament to the peritoneum of the anterior abdominal wall.

Dr. A. E. BENJAMIN of Minneapolis stated that he kept his patients in the Trendelenburg position for from four to six weeks before operation in order to accustom the abdomen to the higher position of the viscera. He used the x-ray to locate accurately the displaced organs.

Dr. GOLDSPOHN of Chicago emphasized the necessity of changing the shape of the abdominal walls, since he believed that their relaxation played a more important part in the support of visceral organs than did that of the mesentery itself.

Dr. COFFEE, in closing, said that his patients had been in bed from six months to two years before operation.

Thursday, June 29—Third Day.

Election of Officers.—The following officers were elected: *Chairman*, Dr. C. Jeff Miller of New Orleans; *Vice-Chairman*, Dr. B. Somers of San Francisco; *Secretary*, Dr. F. F. Simpson, Pittsburg, Penn.; *Executive Committee, Dr. H. G. Wetherill* of Denver, Col.

Uterovaginal Prolapse in Elderly Women.—Dr. GEORGE B. SOMERS of San Francisco commonly found this condition in elderly women who had borne many children. He discussed the relative value of total hysterectomy and the interposition of the uterus between the anterior vaginal wall and the bladder. He favored the latter operation, since it prevented the recurrence of cystocele better than any other method of which he knew. It was a comparatively easy and safe operation. He repaired the perineum before the patient left the table, since a good perineum was very essential in all these cases, which as a rule had been badly lacerated.

Dr. PHILANDER HARRIS of New Jersey opened the discussion by saying that he did not believe in the removal of the uterus for slight prolapse or cystocele, since in most cases a less radical measure sufficed. He said his own operation of fixing the uterus into the abdominal wall was not planned to cure cystocele.

Dr. S. M. D. CLARK of New Orleans had done the Watkins operation, but had a recurrence of the prolapse. He then brought the anterior vaginal wall up to the anterior abdominal wall and fastened it there, since which time there had been no recurrence of the trouble.

Dr. L. G. BOWERS of Dayton, Ohio, recommended shortening the anterior vaginal wall to give added strength to the fascia supporting the base of the bladder.

Dr. FRANK TOPPING of San Francisco said that, after all, time was the test of the reliability of an operation. To the clinics came many women who had been repeatedly operated upon, but with several recurrences. He found that the majority of plastic operations failed and relapses occurred.

Dr. SOMERS, in closing, said that he favored saving the uterus whenever possible, because it was a better support for the bladder than anything else so far tried. He did not believe in shortening the anterior vaginal wall, because it did not keep the cervix high enough, and might cause its presentation at the vaginal outlet.

Special Considerations in the Treatment of the Female Pelvic Organs.—Dr. HENRY PARKER NEUMAN of San Diego, in this paper, made a strong plea against the useless removal of the pelvic organs in women. He said the province of gynecological surgery was to preserve all possible structures, and the organs should never be removed en masse, except as a life-saving measure, as in cancer or hemorrhage. He favored shortening the round ligaments at the internal ring, since there were no adhesions at this point, and pulling on the ligaments caused very little or no trauma. He emphasized the fact that early, skilful plastic gynecological surgery was very essential, since it tended to prevent subsequent more serious conditions.

Dr. WHITE of Chicago said that pelvic prolapse was not a pelvic hernia, and should not be called that. He said the pain after herniotomy was due to the implication of

one of the two large nerves in that region, and could be avoided by first isolating these nerves, and so not including them in the sutures.

The Proper Operative Period and Methods of Drainage in Pelvic Infections.—Dr. L. G. Bowers of Dayton, Ohio, read a paper on this subject, illustrating his points with pictures. He believed that an early radical operation prevented much useless office treatment. In the case of a chronic pyosalpinx he drained through the cul-de-sac with a large gauze drain which was removed on the fifth day. In the gonorrheal infections he used palliative treatment during the acute stage, followed by a radical operation a little later.

The Employment in Abdominal Surgery of Two Rubber Drainage Tubes with a Single Stab Wound Exit, Instead of a Single Tube with Exit by Incision or Otherwise Wherever Drainage Is Desired.—Dr. Philander Harris of New Jersey said he used two sets of double rubber drainage tubes, with a wick of gauze, one set of which tubes he placed in the infrafascial, and the other in the suprafascial space, for the purpose of draining the blood and serum which collected in nearly all cases. In intra-abdominal drainage he also used double tubes which had their exit in a stab wound several inches from the incision. He showed pictures of the tubes in place, and also had tubes passed around among the audience.

Dr. Frank T. Andrews of Chicago did not believe in draining every abdominal incision. He said if we prevented mutilation of tissue infection would rarely occur. He used strands of silk-worm gut in draining the abdominal cavity.

Dr. Bowers, in closing, thought we needed no abdominal wall drainage if we were careful to obliterate all dead space and cause as little trauma as possible.

Dr. Harris, in closing, said that in a series of over 2600 cases less than 50 showed no oozing of serum or blood. Therefore intramural drainage was justifiable. He recommended a trial of his method of draining.

Postoperative Complications.—Dr. F. F. Simpson of Pittsburg said there were two things we could do; either prevent these complications or else recognize them early and give them intelligent treatment. He showed some of his charts in the postoperative cases. An exact hourly record was kept of temperature, pulse, respiration, urination, emesis and abdominal distention. Thus one could study each function separately and then study their relations one to the other. By so donig one could recognize complications very early and by the early treatment thus made possible lower the mortality.

Two Years' Experience with Vaccines in Obstetrical and Gynecological Infections.—Dr. John O. Polak of Brooklyn, New York, read this paper. He had used the vaccines in a large number of cases, particularly of postabortive and peurperal infection. Blood counts were taken before and after vaccination and blood cultures of the organisms were obtained whenever possible. Patients reacted to injections by a feeling of well-being even before the temperature and pulse showed any change. Small doses were given at first and were repeated as soon as blood examination showed an indication. His results were better with stock vaccines than with autogenous ones. He reported several series of cases according to groups of infections. The results were excellent, especially in thrombophlebitis, chronic mastitis, and pyelitis due to the colon bacillus.

Dr. Frank T. Andrews of Chicago believed that the vaccine treatment in the acute cases was a dangerous method and wished to know how much of a reaction there was in the local lesion.

Dr. Polak, in closing, said that the vaccines were good in the very early acute cases, but the late acute cases were not improved. In septic abortions the usual operative procedures were instituted and the patients were given a dose of mixed vaccine before they left the table. There was no local reaction at the site of the lesion after the use of vaccines.

Primary Carcinoma of the Fallopian Tube.—Dr. E. E. Montgomery of Philadelphia presented this communication. The cervix and ovaries were very liable to cancer on account of injury and constant physical changes, but it was rather rare to find a primary carcinoma of the tube. It was usually associated with an ovarian cyst. Carcinoma of the tube presented no characteristic symptoms. It was usually preceded by salpingitis, and even if removed by operation frequently did not look pathological, and its nature was diagnosed only by microscopic examination. His case was diagnosed as one of retroversion and prolapsed ovary. Operation showed a mass on the end of one tube, which was removed and shown to be a carcinoma. Subsequently a hysterectomy was performed, with recovery and no recurrence. The opposite tube was tuberculous and there was a myoma of the uterus.

Change of Name.—The recommendation made by the Chairman, Dr. H. G. Wetherill, in his annual address, that the name of the section be changed to "Section on Obstetrics, Gynecology and Abdominal Surgery," was approved and the section ordered it referred to the House of Delegates.

Prolapse of the Gravid Uterus.—Dr. Palmer Findlay of Omaha read this paper. He said that a number of cases had been reported of complete prolapse at full term, but few were other than elongation of the cervix. It was most rare in primiparæ. The uterus might be prolapsed before labor or there might be an acute prolapse in labor. Pregnancy was unlikely in an already prolapsed uterus. There might be spontaneous reposition, but abortion more likely and postabortive and puerperal infections were common. Labor was lengthened and rupture was likely unless the cervix was incised. His case was in a multipara at three months. The entire uterus could be delivered by traction. He emptied the uterus, did an amputation of the cervix and an anterior colporrhaphy and perineorrhaphy. Some uteri could be replaced in the knee-chest position and retained with pessaries. If the head was engaged at or near term there should be no attempt at replacement, but bilateral incisions and version or forceps were preferable. In several cases the organ had been replaced, the cervix amputated and the pelvic floor repaired without interrupting pregnancy. Abnormal presentations were frequent in these cases.

Dr. Arthur E. Hertzler of Kansas City reported a case in a primipara, in which the uterus was replaced and retained by posture in bed, carried to term, with normal delivery. Later the cervix was amputated and the perineum built up.

Dr. W. B. Dorsett of St. Louis related a similar case in which the woman, after being kept in bed for six months, aborted. She was subsequently operated upon, perieorrhaphy, anterior colporrhaphy and Gilliam operation being performed.

Dr. Frank T. Andrews of Chicago had done an extavaginal hysterectomy in a case which had formerly had a normal delivery after the uterus had been replaced and the patient was kept in bed.

Pernicious Vomiting of Pregnancy.—Dr. C. B. Ingraham of Denver presented this paper. He classified these cases as of reflex, neurotic and toxic types. In his case an abortion had previously been performed for pernicious vomiting. In her second pregnancy a dermoid cyst was removed, but the vomiting continued until lessened by suggestion, the neurotic element being marked. He believed that a prominent etiological factor in these cases was an autotoxemia, the cause of which might be one or more of such factors as toxin of placental origin, intestinal

putrefaction, and changes in the thyroid and parathyroid secretion. Starvation might have some influence in determining the nitrogen contest of the urine, but did not explain all of the symptoms. Increase in ammonia was a danger signal, but not in itself an indication to terminate pregnancy. The large amount of ammonia was due to decreased urea formation on the part of the liver, and evidence of impaired hepatic function could be noted in urinary findings after saccharine diet. He mentioned the liver findings after the use of chloroform, which made this drug contraindicated in toxemias.

Dr. JOHN O. POLAK of Brooklyn said that he did not believe there was ever a true neurotic type. Reflex conditions might have an influence. Care should be taken not to let these cases go too far before aborting them.

Dr. T. M. BURNS of Denver had seen these cases cured by suggestion.

Dr. C. JEFF MILLER of New Orleans believed that some of these cases were helped by gastric lavage.

Dr. FRANK T. ANDREWS of Chicago cautioned against the use of bromides on account of the danger of acne of the amnion and subsequent congenital deformities due to amiotic adhesions.

Dr. G. R. NEFF of Farmington, Iowa, suggested the use of salted almonds and peanuts in some cases, in which other food could not be retained.

Dr. CHAS. T. PALMER of Los Angeles had seen thinly sliced, well-browned bacon retained by patients in extremis.

Dr. INGRAHAM, in closing, emphasized the neurotic element as an important factor in some cases.

A Study of Cholecystitis and Cholelithiasis in Their Relation to Pregnancy.—Dr. LAURA H. BRANSON of Iowa City, Iowa, in her communication discussed the character of infections of the gall-bladder. Human bile was not sterile, though animal bile was usually so. Bacteria might exist for long periods in the gall-bladder, in dormant condition. Authorities differed greatly on the true function of the gall-bladder. With progress in the development of symptomatology we had reached a point where accurate diagnosis was usually possible. Ninety per cent. of patients having gallstones had borne children and 90 per cent. of these patients dated the beginning of gallstone disease to some particular pregnancy. Metabolism in pregnancy was greatly altered, in the latter months elimination being decreased. Bile remained sterile only when its flow was unimpeded and pressure on the liver by the gravid uterus impeded the flow sufficiently to account for infections and disease. Cardiovascular changes were common with cholelithiasis. It was possible to operate for the gallstones even in the presence of these changes. The author presented three typical histories and concluded that physiological pregnancy furnished sufficient etiological factor, and pathological pregnancy furnished the etiological agent direct.

Dr. PALMER FINDLAY of Omaha wished to have explained the attacks in early pregnancy, and not in later months.

Dr. BRANSON in closing said that in the later months of pregnancy there was a physiological adjustment which overcame the etiological factors mentioned.

Cesarean Section: Indications and Technique—Report of Eighteen Cases.—Dr. T. MITCHELL BURNS of Denver, in his paper advised section in eclampsia with rigid cervix, central placenta previa, certain cases of ablatio placentæ, persistent nonengagement of the head, and death of the mother. He said that infected cases did as well as after high forceps. He advised the Porro operation in cases complicated with carcinoma, sarcoma, and certain fibromata. The usual preparation was made for laparotomy, an 8-inch incision was made in the left rectus, one-third inch above the umbilicus; a 6-inch incision was made in the uterus, cutting through or displacing the placenta and delivering the child, followed by a small idoform gauze pack of the uterus, which was closed with interrupted sutures; this constituted his technique. The omentum was placed behind the uterus in order to wall off the peritoneal cavity. In clean cases the uterus was not removed from the abdomen. His cases had a very low mortality and little morbidity.

Dr. JOHN O. POLAK of Brooklyn said that the section was performed in the interests of the child, which he did not think were great in ablatic placentæ and eclampsia on account of the high fetal mortality. He did not eventrate the uterus and urged the use of light oxygen and other anesthesia to prevent fetal asphyxia.

Dr. BURNS, in closing, said that he performed the operation early in eclampsia when the fetal mortality was not high.

SECTION ON DISEASES OF CHILDREN.

Wednesday, June 28—Second Day.

The Influence of Summer Heat in the Production of Gastrointestinal Diseases of Infants.—Dr. I. A. ABT of Illinois in reading this paper covered carefully the literature of the subject and stated that bacteriological and dietetic causes could not wholly account for the disorder. He stated that in his experience there were fully seven times as many bottle-fed infants affected as breast-fed. In conclusion he expressed the conviction that temperature was the most important factor, that it should be lowered as much as possible by frequent bathing and light clothing, that home hygiene should be regulated, and the importance of keeping the child out of doors emphasized.

Dr. FOSS of Arizona said that in his State, where the summer weather was very warm and the wet bulb was never below 72 and frequently as high as 115, summer diseases in children were almsot unknown, so that he considered that the question of heat should be eliminated.

Dr. MAGEE of California stated that while in California the humidity was much greater than Arizona, yet in his practice he had practically no summer diarrhea. He said that he did sometimes have gastrointestinal diseases due to improper feeding, but not the summer diarrhea as seen in the East. He believed, therefore, that electrical conditions must enter into the problem.

Dr. WEEMS of Texas thought that the apparent discrepancy in these statements was to be accounted for by humidity, that where it was dry the moisture of the child's body lowered its temperature, while the humidity of the East prevented this natural protection against summer diseases.

Dr. GENGENBACH of Colorado agreed with Dr. Abt that heat did play an important role in these conditions. He said that although in Denver they did not have the excessive heat experienced in the East, still he could see a marked disturbance in the babies under his care during a hot spell. He thought that the question of food could not be entirely left out of consideration, for he had noticed that when he lessened the amount of cream fed to his patients during the disease he had had good results.

Dr. ALLEN of California stated that from her six years' work with the Chicago Children's Home and Aid Society she had observed marked difficulty in keeping the mortality rate low during the excessive heat.

Dr. BUTTERWORTH of Louisiana presented and explained a mortality chart made from statistics gathered in New Orleans and said that, from a study of this, he had come to the conclusion that we must not lay too much stress upon heat.

Dr. ROYSTER of Virginia had noted that in his section of the country where the weather was excessive for a week or two in May and was followed by a cool spell the

patients got better during the cool weather, then in June the highest mortality of the year was reached. He also had remarked that he had no consultations from country practitioners, showing that out-of-door conditions did have a beneficial effect in spite of the fact that the thermometer registered the same. Children practically prostrated in the morning, when taken to the seaside to spend the day come back markedly improved. In his experience the character of the discharges in these cases changed from year to year, watery one year, and bloody and mucous the next.

Dr. Abt in closing said that some very valuable statistical information might be gathered by the appointment of committees from different sections of the country to investigate the matter.

A Statistical Investigation Relative to the Influence of Various Methods of Infant Feeding on the Morbidity and Mortality of Infants.—Dr. W. W. Butterworth of New Orleans said that from August 1, 1909, to July 31, 1910, he had recorded the deaths of 1,314 infants and compiled data of more or less detail as to the feeding in 884 of the cases, the age, sex, color, legitimacy, nationality, and health of parents, the hygienic conditions of the homes, their education, etc. As complete data as possible of the water supply, table food, the ailments of early life, with especial reference to gastrointestinal disturbances and symptoms, and the general development of the child. From this investigation he concluded that the temperature of the summer is but one of many causative factors. Improvement of sanitation reduced the mortality 50 per cent. and he thought that with education regarding the necessity of breast feeding it would be still more lowered. He attributed part of the lowered mortality to the outdoor living and the use of condensed milk which was low in fats.

Recent Experiences in Artificial Feeding of One Hundred Infants During the First Three Months of Life.—Dr. F. C. Neff of Kansas City, Mo., concluded that the regain of birth-weight was no slower in bottle-fed than in breast-fed infants, that the normal rectal temperature was 98.6°, and that a higher temperature should be regarded as pathological. He does not consider peptonizing of milk particularly advantageous in young infants preferring buttermilk, skimmed milk, or malt soup.

Dr. Southworth of New York called particular attention to diagnosing signs of "no milk." He said that the necessity for physiological adjustment between mother and child must not be overlooked and that it would many times account for the child not getting the milk which was really there. He believed that too frequent application to the breast tended to decrease the quantity. He condemned the practice of attempting to fit a proprietary condensed milk to all children and said that he would expect to find rickets in all children so fed.

Dr. McLaren of California had noted that babies under six weeks old would gain in weight rapidly if temporarily fed on condensed milk and would afterward be put upon a modified formula of cows' milk.

Dr. Dranga of California believed that condensed milk had a very definite place in infant feeding because it was essentially clean, lower in fats, and easily adaptable to the needs of the child. He called attention to the lower mortality among poor children of London who were fed on condensed skimmed milk with the addition of cod liver oil to augment the fat. He thought that the common custom of placing children to the breast every two hours had something to do with the lowering of the quantity.

Dr. Sedgwick of Minnesota reported a lower death rate in Minneapolis than that given for New Orleans, but said that it was higher in the summer than during the rest of the year. He also had noted difference in the discharges from year to year, there being distinctly catarrhal one year and changed entirely the next. He considered casein milk of definite value in cases of summer diarrhea and in atrophy.

Dr. Tubbs of Iowa said that condensed milk had nothing to recommend it except its sterilization. He believed that food had as much to do with the etiology of summer diarrhea as anything else.

Dr. Tilton of Arizona said that he had not seen a case of scurvy in cases in which condensed milk was used.

Dr. De Buys of Louisiana reported a high mortality in his section, which he thought to be due to ignorance among the negroes, and to the fact that institutions were under religious supervision rather than medical.

Dr. Abt of Chicago advanced the theory that one was justified in resorting to any form of feeding found to be good in the locality, that the question of feeding was more or less in an empirical stage, an dthat only through careful study and unbiased experimentation could anything like a definite conclusion be arrived at.

Dr. Royster of Virginia said that he had never fed a baby on condensed milk, but that nine out of ten of the children coming to him in pitiable conditions of malnutrition were on condensed milk. He fed them on a solution of milk sugar until a formula of cows' milk could be tolerated.

Dr. Francis of Los Angeles said that he frequently recommended goat's milk when the necessity for weaning arose.

Dr. Magee of California also advocated goat's milk, expressing the belief that if people understood the value of the milk as a food, and the ease of keeping the animal where it could be milked at will, the milk then being fed immediately to the child, it would come more into use. He called attention to the fact that a goat was never tuberculous, that tuberculosis could not be produced by inoculation in a goat.

Dr. Butterworth, in closing, called attention to the fact that he was not advocating condensed milk, but had merely showed the figures. He said that probably if these very children had had a modified milk even a greater percentage of them would have lived. He said that the city having settled matters of sanitation would take up systematically the matter of feeding to conserve the life of its infant population. He contended that there was no greater fallacy than that condensed milk was a sterile preparation, that government reports showed it to be reeking with bacteria. He stated that goat's milk more nearly approached mother's milk than anything yet known.

Dr. Neff, closing the discussion of his paper, said that it was his principle not to boil milk when giving the malt extract, but he did not know whether it had any effect on scurvy or not.

Relation of Gastric to Pancreatic Fat Digestion in Infants.—Dr. J. P. Sedgwick and Dr. F. W. Schultz of Minneapolis presented this paper, which was read by Dr. Sedwick. It reviewed gastric lipase in adults and infants, pancreatic fat digestion, and the importance of lipase in the digestion of emulsified fat in milk. Fat-splitting elements were found in the stomach at least as early as the fourteenth day. He gave a résumé of their studies in lower animals and infants from which he concluded that the function of gastric lipase was not needed in the infant after the duodenum had been reached.

The Neurotic Basis of Juvenile Delinquency Based on Some Special Cases of the San Francisco Juvenile Court.—Dr. Philip King Brown of San Francisco stated that too frequently what was called and treated as crime in children was the natural outcome of environment and bad training. When these conditions were changed, he said, a long step in the right direction would have been taken. He affirmed that it would be a fallacy

to attempt to outline a definite treatment for these unfortunates, and in conclusion he asked that the Section take some action toward recommending that the delinquency of children be placed upon a different footing in the courts.

Dr. Colliver of California said that in an investigation of some 3,000 children it was found that environment played the most important part. Ninety-five per cent. of these 3,000 children, he stated, came from homes which for one reason and another were disrupted and the matter of discipline was neglected or totally lacking. He thought that many of these conditions had their beginning in physical conditions which, by slight operation, such as circumcision, tonsillectomy, or the removal of adenoids, were markedly benefited. He said that in sections of Los Angeles where playgrounds were established the number of appearances in court were lessened.

Dr. Royster of Virginia asserted that delinquency and dullness in school went hand in hand and as contributing factors to these conditions must be taken into account physical development, environment, and heredity. He said that the mentally deficient might be classed into three groups, viz., those which could be corrected, those that might be taught trades and become self-supporting citizens, and finally those of a third class for which nothing could be done. He said that Goddard in his work had examined some 2,000 cases, all of which were traced back four generations, and in not one single instance was there no trace of heredity in the condition shown. As a prevention of this lamentable condition Dr. Royster suggested care and education and the prevention of the unfit from reproduction.

Dr. Burnham of California urged need for attention to the normal boy, giving him a vent for his surplus vitality as the best measure.

Dr. Hanson of Ohio brought forcibly to the front the improvement in the public school systems, the prevailing method of medical inspection of school children, and stated that these measures would aid materially as the delinquent child was usually a pathological individual.

Dr. Chapin of Baltimore said that as a result of his experience with playground work and at the Johns Hopkins University, he had come to the belief that the establishment of playgrounds in all large cities would prove the salvation of the coming generation.

Dr. Philip King Brown, in closing, expressed his belief in the underlying goodness of most boys and agreed that the greatest requisite for their development was a safe channel for the outlet of high spirits which was being rapidly met by the playground.

A Consideration of Obstructions at the Pylorus Occurring in Infants.—Dr. Langley Porter of San Francisco considered the pathology of the condition and discussed the classical symptoms in general which would indicate the necessity for operation, and those occurring in cases which recovered spontaneously. He said that successful operation brought complete and almost immediate amelioration of symptoms and that the greatest number of recoveries were characterized by the regurgitant type of vomiting, but that at best little had been gained which would serve in the matter of treatment. The presence of lipase seemed to have some affect upon the spasm in these cases. External heat was sometimes of value, as was also condensed milk and other modified foods, especially when combined with milk laxatives. In conclusion, he said that, while his experience was too limited to admit of positive statements, still he believed that patients having regurgitant vomiting had a better show than those in whom it was cumulative. He urged the need of further study.

Dr. Butterworth of New Orleans lamented the puzzling nature of these cases as shown by the fact that patients upon whom operation was not permitted, although it was believed by the physician to be the only proper method, frequently recovered. He noted the frequency of this condition in boys and in the first born of families and frankly confessed his inability to draw a line when to operate and when not. He said that his best results had been obtained from frequent stomach washings with bicarbonate solution, antispasmotics, and belladonna.

Dr. Porter, in closing, said that he had used belladonna with some success. He said that he had found much to think about in the occurrence of five deaths in the fourteen cases, two under operation. He said that they used an anesthetic in attempting to find the tumor and had never seen ill results. With the development of gastritis he began stomach washings, and said that from that time on the child was able to digest fats.

The Relation of Meat Ingestion to Indicanuria in Childhood.—Dr. E. C. Fleischner of San Francisco presented this paper which was read by Dr. Porter. He stated that repeated tests showed no indicanuria in normal childhood. That a series of tests in an institution showed no indicanuria when children from three to twelve years of age were fed two meals of meat a day, but in children of three years and younger there was quite a marked percentage of indican present, from which he concluded that the diet of young children should be regulated in this respect.

Dr. Sedgwick of Colorado stated that such experiments were of more value in children than adults because of the tendency to indicanuria in adults.

Dr. Porter, closing the discussion, said that the work of Dr. Fleischner has a distinct value in pointing out that irritability in children was frequently due to indicaturia, and so universally was this case that he had been diagnosing heavy indican reaction in exceedingly irritable children.

Thursday, June 29.—Third Day.

Election of Officers.—The following officers were elected: *Chairman*, Dr. I. A. Abt, Chicago, Ill.; *Vice-Chairman*, Dr. L. T. Royster, Norfolk, Va.; *Secretary*, Dr. J. P. Sedgwick, Minneapolis, Minn.; *Delegate*, Dr. Wm. C. Hollopeter, Philadelphia, Pa.

Rachitis in Its Early Stages.—Dr. J. W. Cokenower of Des Moines, Iowa, called attention to the crying need for more specific attention to the etiology and early treatment of this condition, saying that it should be recognized as a constitutional disorder in which medicines were secondary to hygiene, proper feeding, and fresh air. He said that particular attention should be paid to the probably cause of the condition, its diagnosis, and therapy, and closed with a résumé of the brief literature recently published.

Dr. Follansbee of California also emphasized the need for early recognition and expressed the belief that adenoids played an important part in causation. She said that in her opinion adenoids were not infrequently congenital, that she had had them removed as early as the fourth day with beneficial results to the nutrition of the child.

Dr. Cokenower, in closing, said that although the condition was one to be met with frequently in any practice, it was rare to have it the subject for discussion at a medical meeting, or of a paper in the medical journals. He said that it not only resulted in contortion of bones, but produced muscle changes, causing difficulty in the normal functions of the organs, and that many of the deformities so trying in later life had their origin here.

Report on Brain Cases in Children.—Dr. William J. Butler of Chicago made a report of two cases under his care at Cook County Hospital in which he gave a complete analysis of the symptomatology, physical findings, diagnosis, pathology, and the result of spinal puncture, emphasizing its importance in the analysis of a cerebrospinal lesion.

Dr. C. C. Rogers of Chicago said that the symptoms of these conditions could not be mistaken for anything else.

MALIGNANT ENDOCARDITIS IN NEW YORK CITY; A CLINICAL STUDY.

BY THOMAS E. SATTERTHWAITE, M.D.,

NEW YORK.

MALIGNANT endocarditis is a very serious disease, often difficult of diagnosis, and usually fatal, even if all the resources of the physician have been called into play. Among pathologists it is believed to be a simple endocarditis which has become infected by poisonous germs. It then assumes so grave a type that the word malignant is an apt prefix. How long it has been known under this name is difficult to say; Bouillaud in 1835 found that it had been in use before his day. This great diagnostician described both a typhoid and a septic type, which latter he called gangrenous; he also recognized three varieties, the acute, subacute, and chronic. In 1889 the term malignant endocarditis appeared in Wilkes' and Moxon's Pathological Anatomy, apparently because in 1882 Goodhart of Guy's Hospital found a group of fatal cases associated with typhoid and scarlet fever.

Simple endocarditis, meaning the non-malignant variety, is not to be regarded as a fatal disease, except in so far as it produces death mechanically through embolism of some important organs, the brain or basal ganglia, for example. Even cerebral embolism may occur a number of times before there is a fatal issue, which only results after the embolism has cut off the blood current from important nerve centers.

Malignant endocarditis is so rare a disease that no one person can have had much personal experience with it. Nor can anyone discuss it intelligently without having studied a large number of cases at first hand. I have had the unusual opportunity of studying one hundred cases in the record books of some New York hospitals, and the chief object of this paper is to present a brief analysis of what my examination has yielded. In so doing I take this opportunity of thanking the officials of the several hospitals for the privileges they have accorded me and the facts they have put at my disposal. It is needless to say that I have endeavored to be accurate in the brief analysis I have made. There was no selection of cases; they were tabulated in the precise order in which they occurred in the several hospital books.

With regard to the infecting agent, only those of the streptococcus, staphylococcus, pneumococcus, and gonococcus groups were recorded, either as having been found in the living blood or in the body after death. This list is a limited one, if we consider that the meningococcus, the *Bacillus coli*, the *Bacillus typhosus*, the Klebs-Loeffler bacillus, the gas bacillus, and probably others have been charged with causing the infection. Apparently there are epidemics of the disease, as is implied by the fact that Billings in eleven out of fourteen cases found the pneumococcus as the infecting agent (78 per cent.) Among the associated systemic diseases I found rheumatism in more than one-third of the cases, and suppurating foci, pneumonia, pleurisy, phthisis, syphilis, gonorrhea, influenza, tonsillitis, chronic peritonitis, chronic appendicitis, colitis, and nephritis in varying proportions.

Unfortunately for scientific nomenclature, the affix ulcerative came to be used for this form of endocarditis, though ulceration merely represents one of the regular events in the simple form. In fact, it has been claimed that infection of valves may occur without ulceration of their surfaces, just as in diphtheria we occasionally see a diphtheritic patch on an unabraded surface. Less objection is to be charged up against the words infective and infectious, and yet we have not thus far been able invariably to find the pathogenic germs, so that these terms constitute a begging of the question. In fact, in my one hundred cases the germ was found in only 33 per cent. The same objection applies to the word mycotic, which is sometimes used. In speaking of the septic form, we of course allude to those assigned to the streptococcus, the staphylococcus, and other pus-producing germs.

In this connection I should state that the cases of which I present a brief analysis were sometimes examples of mixed infection. Thus, in my one hundred cases, of which thirty-three showed specific germs in the blood or elsewhere, streptococci were found alone in eighteen; staphylococci occurred jointly with them in one; staphylococci occurred alone in five; pneumococci were associated with them in two; pneumococci occurred alone in six; and the gonococcus in one. It is clear, therefore, that the predominating germs found were of the pus-producing varieties.

In malignant endocarditis there is a poisoning by implantation in the inflammatory deposit of the valves; in adults chiefly those of the left heart, and in infants of the right heart. The poisoned emboli, together with aggregations of bacteria, are carried forward by the blood current into the greater circulation, infecting the entire system.

As to the frequency of malignant endocarditis in this city, in the Babies' Hospital of this city, in a total of 8,775 admissions during the term 1900-1911, the records do not show a single instance of the disease. This institution presumably limits its admissions to those under three years of age. In the New York Hospital and St. Luke's, during a similar term, with admissions numbering 102,631, but one case had been recorded of a child under three years of age. So that under the age of three or four it must be extremely rare; in fact, it almost never occurs.

My statistics, based on 100 cases, are as follows: Under 14, 7 per cent.; between 20 and 30, 25 per cent.; between 30 and 40, 30 per cent.; between 40 and 50, 18 per cent.; between 50 and 60, 4 per cent; over 60, 1 per cent.; age unknown, 15 per cent.

We are led to believe, therefore, that this is largely a disease of early middle life, occurring with greatest frequency between the ages of thirty and forty, almost never under four, and seldom before fourteen or after sixty. Unfortunately, however, it is not possible to verify this statement by any official data obtained by governmental inquiry. For we are confronted by the fact that malignant endocarditis is not mentioned in the international list of the causes of death furnished by the Department of Commerce and Labor, nor does it appear in our National Census tables, or in the reports of our State Department of Health or our City Department of Health. The following abstract of a letter written me by Dr. William H. Guilfoy, Registrar of Statistics in our City Board of Health, under date of February 11, 1911, illustrates the prevailing method by which the returns are made by physicians in our city. He says: "I am unable to furnish you with definite figures in regard to the number of deaths from malignant endocarditis, either acute, subacute, or chronic; and, by the way, I do not remember ever having seen a death ascribed to chronic malignant endocarditis. My impression is that a majority of the deaths which are classified under acute endocarditis are deaths from acute or subacute malignant endocarditis, which have been reported as either acute endocarditis or septic endocarditis or ulcerative endocarditis."

In the Manhattan State Hospital for the Insane, with a total of 58,042 patients treated during the ten-year term ending September 3, 1910, not one case of malignant (infective or infectious) endocarditis was registered as such on the books. On the other hand, in Bellevue Hospital, where between 1902 and 1908 there were a total of 204,690 patients, 222 were registered as infective (malignant) endocarditis, including both the acute and chronic forms.

My statistics were taken from the records of three of the great semi-private general hospitals, where I was able to get from each the number of patients admitted during the last ten-year term available, together with the number of cases of malignant endocarditis registered during that period. The results were as follows: New York Hospital, 50 cases treated, admissions 88,365; St. Luke's, 45 cases treated, admissions 14,266; Presbyterian, 118 cases treated, admissions 33,592; total, 213 cases treated, admissions 136,223, or one in 639 patients.

In Bellevue Hospital the proportion was 1 out of 922, during a six-year term, with 204,690 admissions.

As a rule, with exceptions in very rare cases, malignant endocarditis is accompanied by fever. In one there was a temperature as low as 98° in a woman of 41, who died with symptoms of chronic peritonitis. She was not in the hospital more than one day, and was probably in a state of collapse when admitted. In the larger number of cases the temperature reached or exceeded 104° F., while in 73 per cent. it varied between 103° and 106°; in 14 per cent. it touched or passed 106°, while in 2 per cent. it exceeded 107°. High temperature, therefore, was the rule. In only 7 per cent. was there temperature under 102°. The pulse rate seemed to vary with the temperature

While in my cases germs were only found in 33 per cent. (in one of the hospitals they were found in 42 per cent.), but sometimes not until after death.

Cultures should be made in every case of the disease, and if the early ones are negative they should be repeated at short intervals, as the microorganisms may not be found until the examinations have been many times repeated.

Petechiæ were noted in 19 per cent. But they must be differentiated from the rose-colored spots of typhoid and from purpura hemorrhagica. In this connection it must be remembered that there is also a purpura rheumatica.

Hemorrhages were occasionally noted, but only in 5 per cent. Implication of the spleen was found in 8 per cent. Headache and diarrhea were frequent, as might be expected. The leucocyte count varied from 6,650 to 36,000; it exceeded 20,000 in only 5 instances. In 21 out of 33 examinations it did not exceed 15,000 (63 per cent.). The hemoglobin content was low, most often under 60. Rheumatism was a concomitant in 37 per cent. Pneumonia came next in frequency (6 per cent.). Tuberculosis existed in 5 per cent.; pleurisy and syphilis each in 3 per cent.; gonorrhea in 2 per cent.; acute and subacute nephritis in 2 per cent.; cerebrospinal meningitis in 1 per cent; mammary abscess, suppurative arthritis, colitis, chancre with suppurative buboes, chronic appendicitis, gangrene of foot, and miscarriage each in 1 per cent.; total, 66 per cent.

Sometimes the diagnosis presents great difficulties, and has to be made by exclusion, for often the symptoms are variable and indefinite and lead to the confounding of the disease with tuberculosis, purpura, typhoid or malarial fever. The subacute or chronic form will perhaps for a time be difficult to differentiate from typhoid. It is here, however, that blood culture comes to our aid, for by the discovery of the streptococcus or the staphylococcus, where the Widal, von Pirquet, and malarial tests are negative in the presence of an endocarditis, the diagnosis of the malignant form of the disease may be made with reasonable certainty.

But we cannot depend absolutely upon culture methods. They fail in a certain number of cases, and the germs may not be recovered during life. We must rely on a diminished leucocytosis and enlarged spleen, hemorrhages, a previous endocarditis, some displacement of the heart, precordial pain, headache, rapid pulse, a temperature that is continuously high, a tendency to septic symptoms, and often suppurating foci somewhere. And inasmuch as the pathological diagnosis may be inconclusive, we must learn not to wait for it, but make, if we can independently, a clinical diagnosis.

Basing our prognosis on the 100 hospital cases, we may conclude that in malignant endocarditis 85 per cent. of the patients die, 10 per cent. improve for a time—how long is uncertain—but that in 5 per cent. there is such a degree of improvement that it may be called recovery, so far as the malignant nature of the disease is concerned. While we cannot put it in the same class with pyemia, the disease is to be classed with the severest forms of constitutional infection.

The duration of the disease may be from a few days to several months. Billings has reported a

case in which the patient lived more than two years. In my one hundred cases the number of weeks spent by patients in the hospital before the fatal issue was from one to thirteen, but the majority succumbed before the end of the fifth week.

Antigonococcal serum was used in 1 case, other sera in 3 cases, and vaccines 5 times, of 100,000,000, 60,000,000, and 24,000,000 strengths. In no case was there recovery under these forms of treatment.

Case I was that of a young man 21 years of age, who entered the hospital with suppurating glands in both groins, due to a chancre. He also had rheumatism. His temperature varied from 97.8° to 99.8° F. He remained in the hospital 13 days, when he was discharged "improved." Apparently his treatment was symptomatic.

Case II was that of a girl of 7, in whom the diagnosis was made by exclusion. The von Pirquet, Widal, and malarial tests were negative. Her temperature rose to 104°, and her case was diagnosticated as one of malignant endocarditis. She improved so that when she was discharged after 13 days in the hospital she was nearly well. The diagnosis was clinical.

Case III was that of a man 30 years of age, who came into the hospital with influenza, rheumatism, and enlarged spleen. He had petechiæ, and a leucocyte count of 10,400. His temperature rose to 102°. Sputum negative. After 4 days he was discharged in good condition.

Case IV was that of a young woman 18 years of age, who entered the hospital with pleuritic effusion and rheumatism. The examination of blood was at first negative, but afterward streptococci and staphylococci were found. Her temperature rose to 105°, but after 96 days in the hospital she was discharged improved. She was ill in all 9 months. The treatment was symptomatic.

Case V was that of a man 25 years of age, whose leucocyte count varied from 32,000 to 18,300, while the Widal test was negative. The diagnosis was subacute rheumatism. His temperature rose to 103°, but under symptomatic treatment it gradually fell, and he was discharged improved. He was 28 days in the hospital. How far this improvement was maintained is a matter of interest to us, for of these cases I have no further information.

As treatment by sera or vaccines was employed in only 9 per cent., evidently the value of this form of treatment had not impressed itself very seriously on the minds of our hospital physicians. There is no doubt that success has followed the use of both sera and vaccines in a large number of cases, but it seems likely that we have heard more of the successes than of the failures. In a recent book on "Serums, Vaccines, and Toxines" (1910) it is suggested that in case of failure with one brand of serum another brand may be successful. It is evident that in streptococcus disease we should not use antistaphylococcal serum, yet apparently this has sometimes been done. Some temporary benefit has apparently followed the use of Hiss's serum. But in my nine hospital cases both sera and vaccines were used ineffectually as to ultimate result. Nor was unguentum Credé, used in one instance, successful.

In any event, the indications are for rest, good and abundant food, the liberation of pus when practicable, and the use of sulphate of quinine and perhaps iodine internally, and supporting treatment generally.

In the five cases I have reported as improved or cured it appears from the records that the success was due to the use of expectant treatment. In them no specific was given, but, so far as I was able to judge, each individual symptom was treated as it manifested itself. And yet, in spite of all I have said, and all that I found from the study of hospital cases, I have been impressed with the idea that Wright often gets remarkable results, and that bacterial therapy has probably come to stay. At the same time it remains for us to discover not only the precise cases in which it is applicable, but more particularly the character of the bacterins or sera to be used and the technique required to produce successful results. Meanwhile the study of my cases demonstrate that a cure is possible in 5 per cent. by the use of symptomatic measures.

Note.—Since writing the above, my attention has been called to an article on bacterial therapy (Synnott, Medical Record, June 3, 1911) which the author regards as contraindicated in malignant endocarditis and puerperal septicemia as soon as the invading bacteria have gained access to the blood stream, causing systemic infection. At best, it is thought to be of problematical value in these cases.

7 East Eightieth Street.

PASTEURIZATION OF MILK IN THE BOTTLE ON A COMMERCIAL SCALE.

By CHARLES E. NORTH, M.D.,

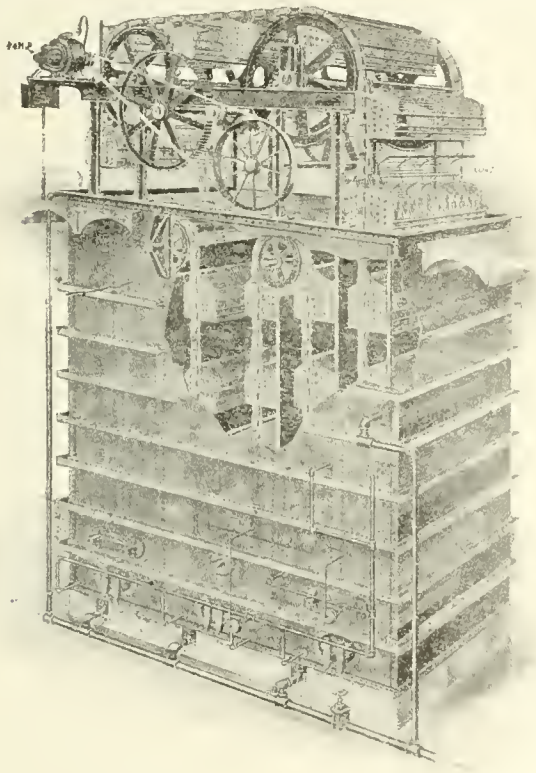
NEW YORK.

During the past three years there has been a large increase in the quantity of pasteurized milk consumed by large cities. The long distances from which milk must be drawn by rail to supply the growing demand of cities have lengthened the time between milk production and milk consumption. The multiplication of dairy farms, which are the sources of supply, has made efficient sanitary control almost impossible. As a consequence, large cities have been brought face to face with a situation which has threatened serious injury to an article of food which is at once the most valuable and the most perishable, and which has latterly proved to be a frequent means for the transmission of infectious diseases. In this emergency it has been proper that public health authorities as well as those interested in the industry should resort to a means for preserving the food value of milk and at the same time protecting the public health, and they have found this in the disinfection of milk by heat.

The application of heat to milk known as pasteurization has gained headway in spite of vigorous opposition from several classes of opponents. Among these, without doubt, the members of the medical profession have raised the most serious objections. On the one hand, there are alleged to be certain injuries to the chemical composition of the milk, and following these are alleged to be injuries to children consuming the milk. On the other hand, the process is said to be a substitute for sanitation and to put a premium on carelessness in milk handling. These objections are, however, not founded on sufficiently substantial ground to offset the important advantages which the process of pasteurization offers. An indication of this is seen in the change of opinion which is going on within the medical profession itself and which is steadily winning new advocates for pasteurized milk.

Perhaps the steadiest opponents of pasteurization are to be found among the physicians practising pediatrics. It was among these that certified milk had its origin, and it is these who chiefly compose the certified milk commissions. In actual practice, however, much of the certified milk which is prescribed is pasteurized in the infant feeding bottle. What has come to be called the "home pasteurization" of milk for infant feeding is widely advocated and practised among this branch of the medical profession. The analysis of their objection to pasteurization shows, therefore, that it is not to the process itself as such, but that it is really an objection to the party by whom the process is performed. In other words, there is a strong sentiment that pasteurization performed by the mother in the home is reliable, while pasteurization by the milk dealer at his milk station is unreliable.

The large milk dealer has given some cause for doubt as to his reliability in this matter. The adoption of pasteurization by the milk industry in the



Beer Pasteurizer: Continuous Submersion Type.

first instance had no other object than the destruction of bacteria-forming lactic acid, and thereby the prevention of loss of milk through souring, particularly during the hot weather. Quick heating by the so-called "flash pasteurization" acts as a preservative, but as commonly practised the process cannot be depended upon to destroy the bacteria causing infectious diseases. This "flash pasteurization" was first adopted secretly because there was no public demand for pasteurized milk, but as pasteurization gained recognition as a public health measure milk dealers gained courage and advertised this imperfect process, and thereby brought reproach upon the term "commercial pasteurization" from which it has not yet recovered.

"Commercial pasteurization," which means the pasteurization of milk by the milk dealer, has some advantages from a public health standpoint which the sanitarian cannot lightly dismiss. These advantages are not guaranteed, however, unless we have in our possession not only a process which is efficient for the pasteurization of milk on a large scale but also a system of supervision which will control the process so that it is always properly operated. It is almost unnecessary to point out that only a small fraction of the milk supply of a large city like New York can be produced under sanitary conditions sufficiently controlled to furnish an insurance against milk-borne infection, either from dairy cattle or from persons handling the milk. The greater part of milk supplied must for a long time to come be of such an uncertain character that the proper application of pasteurization is the only possible guarantee against milk-borne infections. To leave this process to the housewife means a delay of many hours during which there are not only opportunities for additional contaminations to the milk, but for a large multiplication of bacteria in the milk. When one contemplates the varied intelligence among housewives and the fact that in a population like New York City the heating of milk would be done in about 1,500,000 homes, one must admit that the results would vary greatly and in many instances would be ineffective. On the other hand, the large milk dealer has access to the milk from six to twelve hours before the milk consumer. He is also able to pasteurize at one operation many thousands of quarts, and if the operation is an efficient one all of these receive the same guarantee.

In a previous paper ("The Holding Method of Milk Pasteurization," *Engineering News*, May 12, 1910) I pointed out the great advantage which resulted from the adoption by the large milk dealer of the "holding tank," which is a storage tank for heated milk. I showed how by this means it was possible for the milk dealer to pasteurize large quantities of milk in bulk and to have absolute control over the length of time and of the temperature and at the same time make the process a continuous one. From among the numerous comparative tests made of the momentary or "flash process" and the "holding process" of pasteurization, I show below figures which typically illustrate this difference, which are taken from a test of two machines operating in the same plant.

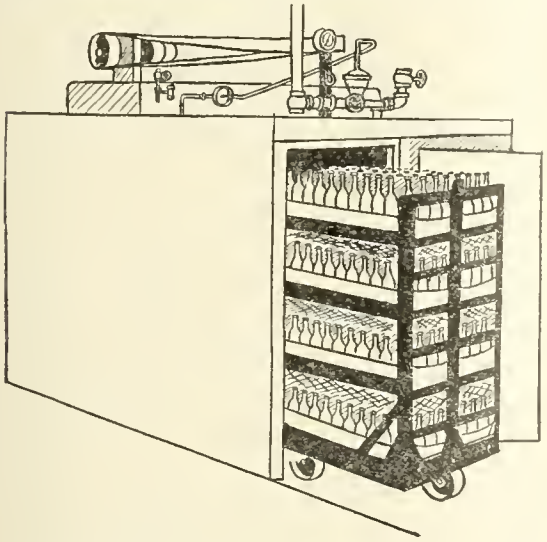
Raw Milk	Momentary Process.	Holding Process.
320,000	50,000	1,500
10,000,000	35,000	1,600
1,670,000	52,000	1,100
940,000	30,000	4,500
360,000	48,000	4,000
330,000	30,000	2,400
Ave.. 2,270,000	40,833	2,518

These figures have been confirmed by the tests which have been made in many of the large cities of this country where the holding process of milk pasteurization has been adopted. The retaining of heated milk in tanks for thirty minutes at a temperature of from 145° to 150° F. has entirely removed the objection raised against the pasteurization of milk by the large dealer on the ground that the milk was not heated for a sufficient length of time. One other great advantage of the use of these retaining tanks has been the fact that it permitted the use of lower temperatures so that while formerly the large dealer heated milk to from 158° to 170° F. momentarily, the temperature can now be reduced to below 150° F., thus avoiding so far as possible injuries to the milk. While this process has resulted in the reduction of bacteria to numbers much smaller than the older processes, yet this has not been the most important result. The time and temperature used have guaranteed the destruction of all of the bac-

teria of infectious diseases transmissible by milk, and this has been the achievement of value from a public health standpoint.

But the large milk dealer has not yet escaped criticism and will not do so until the processes of commercial pasteurization are still further perfected. Within recent years an outbreak of typhoid fever occurred in the upper part of New York City which included eighty-five cases. All of these were persons in households receiving milk from one large milk dealer. The interesting investigation which was carried out by the Board of Health revealed the fact that all of the milk delivered in this section came from one shipping station in New York State in which one of the men employed was a "typhoid carrier." This man's work consisted in putting caps on the glass milk bottles after they were filled with milk. Even if this milk could have been pasteurized by the holding method this outbreak would have occurred, for the reason that the process of bottling and capping takes place after the pasteurization has been done.

A visit to any of the large pasteurizing establishments will show that there are numerous opportunities for the reinfection of milk after pasteurization. When milk leaves the heater it has to pass over



Beer Pasteurizer: Intermittent Shower Bath Type.

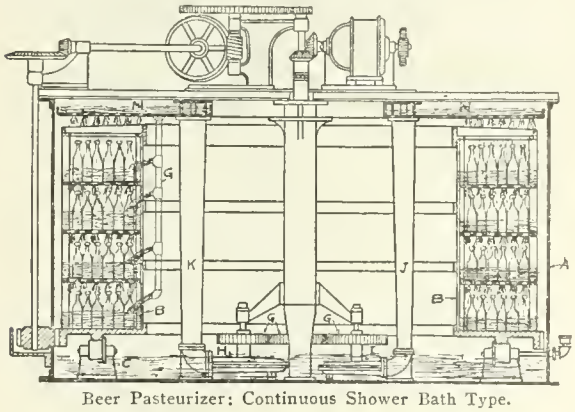
cooling apparatus and through pipes into tanks or bottle-filling machines. From these it runs into the glass bottles, which are then capped. It is exposed to the surfaces of the apparatus and pipes and to glass bottles and caps and to the air of the bottle-filling room and to the fingers of the employees. It may be contaminated by any accidental imperfection in the sanitary control of these sources of infection. In a recent paper published by Dr. Koehler, Assistant Commissioner of Health of Chicago ("The Control of Pasteurization," *Journal of the American Medical Association*, March 11, 1910), the author points out how common this recontamination of pasteurized milk is and gives figures from the large number of bacteriological examinations made under his direction of commercially pasteurized milk in the city of Chicago. A few of his figures illustrate this point. The average of all examinations for the month of January, 1910, at 41 plants, of milk taken directly from the machines was 40,700 bacteria per c.c. Milk from these same plants in bottles on the market gave an average of 277,800 bacteria per c.c. The average of all examinations from 74 pasteurizing plants during July, 1910, samples taken directly from the machines, gave 185,000 bacteria per c. c., while bottled milk on the market from these same plants gave an average of 3,600,000 bacteria per c.c. Dr. Koehler states "as a matter of fact it is impossible in the control of pasteurization on a large scale to eliminate entirely the element of recontamination. Particularly is this true when there are numerous small dealers to be covered who cannot afford the services of bacteriologists. Nevertheless it is obvious that this should be closely studied and an effort made to reduce the recontamination to a minimum. It is, of course, a bacteriological problem and should be handled by trained bacteriologists rather than by the ordinary milk inspector, who has had little or no laboratory experience. That there is much recontamination still going on in Chicago is to be expected considering the fact that the work of pasteurization is at present in a transitional stage."

The "bacteria count" as such is, of course, only an indicator of contamination or of bacterial growth. The real objection to recontamination after pasteurization is the possibility of the infection of milk with the bacteria of disease. If, therefore, the process can be improved to such a point that no reinfection can possibly occur, it is an object to be earnestly desired. This result has already been obtained in the pasteurization of beer. A study of the brewing industry reveals the fact that in the matter of handling perishable fluid on a large scale and distributing the same to the public this industry has gone through a process of development which has carried it many years in advance of the milk industry. Experiences which the milk industry is now passing through are past history in the brewing industry. Brewers have for many years found it necessary to destroy the yeast in beer by heat to prevent the fermentation from proceeding too far. They have also found that the shipping of beer to a distance made it necessary to preserve it from chemical change by the multiplication of organisms, and they applied heat for this purpose. The processes adopted by them in the first instance were very similar to those now practised in the milk industry. Beer was heated in tanks in bulk and was pasteurized before being placed in bottles, but the recontamination of beer through handling subsequent to pasteurization and from imperfectly cleaned bottles and caps gradually forced the brewing industry to adopt measures which would guard against such recontamination. This has resulted in the pasteurization of beer in the bottle. I believe I am safe in saying that all bottled beer on the market at the present time has been bottled first and pasteurized afterwards. A visit to the bottling department of any large brewery will show that the pasteurization of many thousands of bottles of beer in the course of a few hours is a commercial success.

The pasteurization of milk in the home is commonly done in a bottle. The pasteurization of milk in the infant milk depots, and particularly in those operated by Mr. Nathan Straus, is also done in the bottle. These processes are undoubtedly good because the pasteurization includes not only the milk, but also the bottle and the bottle cap, and no further manipulation of the milk is necessary with the exception of refrigeration until it is used by the consumer. But the methods of home and of the milk depots are entirely inadequate for commercial purposes, and for this reason the pasteurization of milk in the bottle has not been adopted by the large milk dealer.

Through the courtesy of some of the large brewers I have had access to their pasteurizing apparatus and have made tests of their process. The pasteurizing of beer is done by several different types of machinery, but in general these are of only two classes. In the first type the beer, after being bottled, is placed in baskets, which are swung from pivots and carried by an endless chain into tanks of water having different temperatures. In this way the bottles travel through water which is lukewarm and warmer until they reach the pasteurizing temperature, which for beer is 142° F. They remain at this temperature for about twenty minutes, after which they pass into the cooling tanks, from which the baskets emerge and the bottles are removed for shipment.

In the other type of machinery the beer bottles are placed on trays which are slid into a compartment of a large wheel revolving horizontally, where they receive a heavy shower bath of water. As the wheel revolves the trays pass into baths of gradually increasing temperatures until the hottest temperature is reached and maintained, after which the baths become cooler until the bottles reach the place of beginning, where the trays are removed. In both types of machine the process may be made a continuous one, and bottles be placed into and removed from the apparatus without interruption.



Beer Pasteurizer: Continuous Shower Bath Type.

It is important to note that the application of heat to beer is accomplished in all types of pasteurizers by means of water. The hot water is applied directly to the external surface of the bottles. The pasteurization of milk in bottles as performed in most of the milk depots is accomplished by the use of steam, and unless raised to a high temperature this does not insure an equal distribution. The pasteurization of milk at low temperatures, I believe, cannot be well performed by steam heating. On the other hand, the temperature of water is much easier to control, and for low temperature pasteurization water possesses advantages over steam, whether the bottles be entirely submerged or whether they be subjected to a powerful shower bath.

The use of water for pasteurization purposes, on the other hand, makes it positively necessary that glass bottles should possess a cap which is watertight. The caps used on milk bottles, while of many varieties, are not such as can withstand the application of hot water for pasteurization purposes without leakage. The brewers have met this situation by placing caps upon beer bottles of tin with a cork lining, which are crimped on to the rim of the glass bottle by machinery. These caps are so formed that they cannot be removed without a special instrument, and they are absolutely watertight.

During the past year the manufacturers of these caps have adapted them to milk bottles and it is now possible to secure these watertight caps in several sizes. The opportunity which the appearance of these watertight caps created for the milk industry was not at once apparent, but it is an event of the utmost importance and opens the way to the adoption of the methods which have proved so successful in the beer industry. In the tabulation below are the results of the pasteurization of milk placed in beer bottles and sealed with watertight caps in a pasteurizer of the submerging type in one of the large breweries in New York City. This machine was pasteurizing many thousands of bottles of beer at the same time at a temperature of 142° F. for twenty minutes in addition to the preliminary heating and final cooling.

	BACTERIA PER C. C.	
Sample.	Before Treatment.	After Pasteurizing.
1	400,000	23,000
2	300,000	9,000
3	57,000	4,500
4	40,000	3,000

From the above table it appears that the process is one which very considerably reduces the number of bacteria in milk. The temperatures used, however, are not as high as those generally used in the holding method of milk pasteurization and consequently the results do not give such low bacteria counts as are sometimes obtained. On another occasion bottles of milk were placed in a machine of the shower bath type in which beer was being pasteurized at the same time in a brewery in Brooklyn, N. Y. The temperature used was 140° F. for fifteen minutes in addition to the preliminary heating and final cooling. The results of this test are given in the table below.

Milk Before Heating.		Milk After Heating.	
127,000	140,000	18,000	20,000
136,000	176,000	23,000	40,000

While the bacteria were reduced, the counts were not as low as desirable, but it must be noted that the temperature and time were less than in the former test and considerably less than is commonly used by milk pasteurizers.

It has been stated by eminent authorities that a temperature of 140° F. for twenty minutes is sufficient to destroy all of the bacteria of infectious diseases commonly transmissible through milk. In practice such a temperature and time do not give satisfactory results in the pasteurization of milk on a large scale, for the reason that the numbers of bacteria are not reduced to a very low figure. Consequently the majority of large milk-pasteurizing machinery is operated at higher temperatures and the ones most commonly in use are from 145° to 150° F. for thirty minutes. As a means of comparison the results which may be achieved by pasteurizing milk in bulk in the ordinary type of machine and pasteurizing milk in the bottle submerged in water I give below the results of a test made for me by Mr. Bixby of Boston.

Bacteria in Raw Milk	Pasteurized in Machine.	Pasteurized in Bottle.
2,000,000	99,000	30,000
2,000,000	102,000	34,000
6,300,000	42,000	6,600
1,960,000	70,000	1,200
6,200,000	65,000	4,000
2,100,000	65,000	8,100

From the above table it is obvious that the submerging of the milk bottles in water gave much better results than the ordinary pasteurization of milk by the large machine even when the same temperatures and the same length of time were used upon the same milk.

It seemed most important to ascertain what would be the results of the pasteurization of milk in the bottle by the use of a beer pasteurizer when the time and temperature were made to correspond with those which are commonly used for milk in commercial practice. Consequently I arranged for such a test at one of the breweries in Brooklyn, N. Y. To reduce the chance of laboratory error to a minimum, forty-eight bottles were filled with milk and were capped with watertight caps. These were placed in the machine in the same position usually occupied by the beer bottles. The temperature of the water applied to these bottles at first was 100° F. This temperature gradually increased until at the end of fifteen minutes it reached 148° F. By means of a controller the temperature was held without variation at this point for thirty minutes, after which it was gradually reduced, so that the cooling process which took place occupied fifteen minutes, leaving the bottles at a temperature of 60° F. They were then removed from the apparatus and placed in ordinary shipping boxes and surrounded with cracked ice, after which they were transferred by wagon from the brewery to the laboratory where they were examined. Samples were taken of the raw milk placed in these bottles and each bottle was separately examined in the laboratory for the results of the pasteurization. One bottle was broken accidentally and two of the bottles were used for drinking to test the flavor of the milk, leaving forty-five of the forty-eight bottles for examination. The results of the test are given below:

Raw milk, bacteria per cubic centimeter in the several samples, 250,000; 450,000; 200,000; 900,000; 70,000.

Pasteurized top layer, bacteria per cubic centimeter, 500; 100; 300; 2,100; 500; 600; 100; 500; 200; 400; 200; 200.

Pasteurized second layer, bacteria per cubic centimeter, 1,000; 400; 200; 600; 1,000; 0; 100; 200; 100; 200; 0; 400.

Pasteurized third layer, bacteria per cubic centimeter, 800; 2,500; 400; 200; 300; 300; 600; 300; 500; 300.

Pasteurized fourth layer, bacteria per cubic centimeter, 600; 400; 600; 300; 1,800; 400; 300; 600; 400; 300; 100.

In making the above laboratory examinations dilutions of milk were used in the proportion of one part of milk and ninety-nine parts of water for the pasteurized milk and, of course, higher dilutions for the raw milk. Consequently, in giving the results of pasteurization, it was necessary to multiply the number of colonies found on the plates by 100 in each instance. A review of the results showed that each plate contained an exceedingly small number of bacteria and consequently from the knowledge which we have of the comparative accuracy of the dilutions it seems fair to assume that if lower dilutions of milk had been used the numbers of bacteria in the pasteurized milk would have been considerably smaller. In any event, the numbers which resulted from this test are very small and perhaps I may be pardoned for saying that among the rather numerous opportunities which have occurred in the past ten years for making examinations of pasteurized milk I have not before obtained from any pasteurizing apparatus of the commercial type results which nearly approached these in excellence.

In less than an hour after leaving the pasteurizer the milk in all of the bottles had developed a distinct cream-line, and the amount of cream appearing at the top of each bottle was sufficient to indicate that the rising of cream had not been in any way impaired. The milk was pleasant to the taste and possessed no odor or taste which would suggest that it had been heated. Of four persons who separately tasted this milk, three stated that the flavor was not altered in any way, while one thought that, although the flavor was pleasant, yet it was slightly different from raw milk.

The control of time and temperature is entirely automatic in a beer pasteurizer. Recording thermometers are used, which register both the time and the temperature and which travel continuously within the apparatus with the bottles while the process is in operation. The records on this chart show the remarkable uniformity and indicate that the process has been brought under almost perfect mechanical control.

It is not customary in the brewing industry to cool bottled beer to the same degree that milk is cooled; consequently pasteurizers of beer are not equipped for cooling to low temperatures. It is, however, only a matter of adjustment to make provision for such cooling as is required in the milk industry. The capacity of the large pasteurizers used for bottled beer is in every respect equal to the needs of the large milk dealer.

The pasteurization of milk in the bottle on a large scale is entirely possible and practicable. The placing of milk in a glass bottle with a watertight seal, followed by pasteurization of the entire package, guarantees against reinfection until the bottle is opened and will place the operation of pasteurization as such above criticism. The adoption of this method by the large milk dealer will, I am sure, be a great step in advance and not only give additional protection for the product, but will also give a guarantee to the milk consumer against milk-borne infections which has not existed up to this time.

30 Church Street.

REMARKS UPON HYPERCHLORHYDRIA AND CHRONIC DYSPEPSIA.*

By CHARLES SUMNER FISCHER, Ph.D., M.D.,
NEW YORK.

The frequency with which hyperchlorhydria and allied states are encountered among chronic dyspeptics would justify the assumption that they exist, or have existed at some period, in most cases of defective gastric digestion. Freud has given us a "Psychopathology of Everyday Life." Some one might give us a Chronic Dyspepsia of Everyday Life, and make the basis of such the hyperacid stomach. The statistics of any gastric clinic will reveal, either by analysis of the gastric contents or by inference from the histories of the cases, that the majority of chronic dyspeptics exhibit this condition, so that we can almost reasonably postulate its existence in an average case of average duration. The literature upon the subject is enormous and more or less confusing as to causes, frequency, variety, and consequences. Each enthusiast has encountered and described a type of his own, with the result that numerous supposititious clinical entities have been evolved ,to follow which would lead to obfuscation of the intellect. In this regard, undue ardor of specialization has effected

*Part of paper read before the Associated Physicians of Montclair, N. J., and Vicinity, December 19, 1910.

a loss of the proper sense of proportion as to the actual existing conditions. To counteract this laboratory enthusiasm and to steady our medical judgment, we may have recourse to the impressions produced by clinical observation of the general trend of these conditions over periods of years.

While such conditions as hyperchlorhydria and hypersecretion do exist apparently in different types, the impression we receive from the observation of large clinical material as to their nature, course, common etiology, and universal treatment would seem to indicate that we have to deal with one process in all, that differences in type are simply varying stages of the same condition, that the excessive secretion *per se*, is but an exaggerated physiological activity, brought into existence by conditions rather than defects. In this connection, it should be remembered that a hyperchlorhydric stomach is a good stomach in the sense that it can perform its enzymotic function properly. Whatever there may be pathological in the condition is due to excessive capability, for while the results may be abnormal, on account of local circumstances, the fundamental principle of the process is one of intense physiological activity for special purposes. Every normal stomach responds to irritation at first by hyperactivity, that is, it pours out sufficient normal secretion to counteract the insult. A stomach which does not do this is defective as to either its secreting structures or its constitutional inspiration, and it can be safely assumed that most cases of subacidity began as hyperacid conditions. The original insults to the mucous membrane produced isolated attacks of hyperacidity, which in the course of time changed to subacidity for local or general reasons. This natural tendency of the normal stomach to hypersecrete upon irritation is, in itself, sufficient reason for the frequency of these conditions. Its digestive functions can be regarded as protective agencies and hyperchlorhydria is an exaggerated digestive function called into existence as one of such. It is a local manifestation of the endeavor of the organism to protect itself through a scheme of general acidity.

The hydrochloric acid of the stomach is but a massive exposition of this plan of defense, for digestion implies self-preservation and self-preservation postulates protection. It is immaterial whether this is accomplished in the digestive tract or in other cellular structures. The antibodies formed for general organic protection are found in the globulin faction of the native proteins. These globulins are acid and give rise to the antitoxins, agglutinins, and precipitins. These latter are produced whether food or toxin be injected into the circulation. Native proteins injected into the blood stream often act as toxins. Certain foodstuffs when first introduced to civilization have acted as poisons. The food which nourishes our bodies gradually merges into the toxins which destroy them and Erlich classifies the toxins as spoiled foodstuffs. The side-chain theory fits the digestion of food as regards the distintegration and assimilation of the protein molecule. "Leistungskern," receptors, haptophores, all act in the process of digestion and assimilation of food as they would in the defense against toxins, so that in its struggle for existence the organism follows a certain general law, either nutritional, as in the process of digestion and assimilation, or antitoxic, as in the operation of immunization. Whether the reactions involved are purely chemical remains to be demonstrated. With the secretions of the pathogenic bacteria largely alkaline and the tendency of animal protection largely acid, it would seem that such were the case. Judged in the light of this knowledge, we must regard the hydrochloric acid of the gastric juice, formed from the common salt of the circulating medium and adapted quantitatively to progressive biological development, as a natural protective agent against bacterial invasion or as a means of self-preservation in the sense of digestion. These facts may appear to be irrelevant to a consideration of such a prosaic condition as chronic dyspepsia with hyperacidity, whereas, in truth, they have a distinct bearing upon the extreme frequency of hyperchlorhydria and the proneness to this state under nervous influences, and may throw some light upon the question of priority in advanced associated disturbances of the motor and secretory functions of the stomach.

If the normally constructed stomach must respond to insult by hypersecretion of acid as a result of progressive biological development, we can readily understand the effects of the tangible and practical influences affecting this organ in the course of daily life. In the hyperchlorhydric temoprary state we have the secret of many of the lesser evils of occasional defective digestion. In this category we may include most cases of common acute indigestion. The vulgar sour-stomach, the popular bilious attacks, and many of the so-called old-fashioned sick headaches. This is not surprising when we consider that the normal human stomach pours out hydrochloric acid in the course of twenty-four hours in sufficient amount, if taken internally in one dose, to produce symptoms of acute poisoning.

The operating causes of hyperchlorhydria or hypersecretion do not differ from those of other affections. They are either remote or immediate. It is only in the ease and rapidity with which the stomach responds physiologically to external influences that this organ differs from the others. The reasons for this have been stated. They are largely biological. These characteristics, however, give to the predisposing causes a certain importance which they otherwise would not possess. We are very apt to disregard hereditary influences in the production of these conditions because there is no evidence of direct transmission, when, in reality, such transmission indirectly through the nervous system is of far greater importance than habit or environment. There is an ancient proverb which says: "When the fathers have eaten sour grapes the children's teeth are set on edge." Outwardly, this is not demonstrable. The classic symptoms of hyperchlorhydria are either masked or unrecognized during the early years of life. That the condition does not exist at this time is not probable, for it occurs acutely at times during the first months of existence. The general lack of inhibitory control inherited by many children is more likely to exhibit itself during adolescent years in general motor disturbances. Vagaries of secretion are not so evident. In the case of the stomach secretions any irregularities may remain dormant until the latent defects of nervous

organization are exposed by the tremendous psychic readjustment occurring at puberty. As a result of the psychological development of this period, a latent hyperchlorhydria may reveal itself or the inborn tendency to the same receive the necessary stimulus for its development. This development will depend somewhat upon subsequent events. If the course of life is laid so smoothly that no great drain is placed upon the nervous system, there may be no symptomatic evidence of irregularity. If, however, as is usually the case, the daily struggle for existence is a strenuous one, any latent tendency will sooner or later reveal itself, habit and environment to the contrary notwithstanding.

With a certain propensity for hyperacidity present in the average normal stomach from birth, it can readily be understood that all indiscretions later will tend to foster this. The foundation for many of these cases is laid during childhood. In the uncontrolled dietetic habits of the average child we may find the primary inspiration. Whereas, in a certain small proportion of children these habits are carefully regulated, in the great majority there is a general lack of supervision, with the result that most children eat more or less continuously and irregularly. The constant presence of food calls for continuous secretory activity, which in the course of time may constitute a habit. This more or less habitual hypersecretion remains physiological just so long as conditions demand it and need give no disagreeable symptoms. There comes a time, however, when a regulation of the diet becomes desirable and a continuous gastric secretion undesirable. From this time on a primary physiological hypersecretion becomes a pathological one. If, at the same time, any latent defects of the nervous system are unfolded, we have the very best conditions for the initiation of the most common form of dyspepsia. Man occupies a position midway between the herbivorous and carnivorous animals. If his habits approximate those of the former, he will secrete gastric juice more or less continuously. If they resemble those of the latter, there will be intermittent secretion. In either case, there will result an adaptability and reciprocity of all the digestive secretions to the chosen scheme. He cannot, however, vary the procedure from day to day without inharmonious action of the whole and functional derangement in general. The symptoms of such derangement will fluctuate according to individual disposition.

It is useless to go into a consideration of the immediate or exciting causes of the ordinary dyspepsias. That they will be likely to cause hyperacid conditions we have seen. They are either physicochemical or psychoneurotic. They act either from within or without the organism. Contrary to popular belief, however, it may be said in a general way that the great majority of our ordinary stomach troubles are due to conditions of life rather than dietetic indiscretions. With the exception of a small proportion of fortunately placed individuals, the average chronic dyspeptic is underfed, not overfed. Under proper conditions the ordinary insults offered to the stomach would have very little effect, for the organ is a very tolerant one. It is insensitive to ordinary heat, cold, mechanical or chemical irritation, in which capacity it is living up to the functional requirements of its development. When it does react to insult it produces its physiological secretion in excess in a purely defensive attitude. Hence, the average chronic dyspeptic always starts with a hyperacid state unless there are very decided constitutional reasons to the contrary. In the course of time this may change to subacidity on account of the structural changes, functional fatigue, or general malnutrition, dependent upon the character of the producing causes. Hence, in a given case, of short duration, without hyperacidity, we are justified in suspecting structural changes in the stomach itself, provided there is no constitutional basis for subacidity.

The conditions hyperchlorhydria or hypersecretion as expressions of physiological hyperactivity may occur in every form of stomach disease irrespective of the original causes. Whether these causes in the beginning operated through the nervous system or through the habits of the individual is absolutely immaterial. A time will come when the two are merged. An original neurosis eventually results in local organic changes from hypo- or hyperactivity and a primary organic lesion will sooner or later involve the nervous system through nutritional and psychological disturbances. Hence, old cases exhibit defective digestion, defective innervation, and defective metabolism. They represent a great class of our chronic dyspeptics, and, as such, belong to the gastrologist, neurologist, and general practitioner. Neglect of any one of these phases or fanatical devotion to any one of them will result in failure to cure. Arrived at this stage they cease to be stomach disease in a strict sense, and treatment amounts to a careful regulation of an inharmonious whole. Often too great laboratory zeal or specialistic enthusiasm does more harm than good.

Much has been written concerning reflex influences upon the acid secretion of the stomach, and attempts have been made to establish a direct connection between such conditions as appendicitis and gallstones and certain abnormalities in the quantity of hydrochloric acid secreted. That excessive gastric acidity and these conditions should coexist many times is not surprising when we consider the frequency of hyperchlorhydria in the general run of gastric diseases. The *modus operandi* of these reflexes has never been satisfactorily explained, but it can be assumed with air safety that, whatever the stimulus may be, the average stomach will respond to it to the extent of its secreting capability, which in an organ of normal strucure means natural hyperacidity. In cases where such hyperactivity does not occur we hear nothing of reflex action. If, however, any causal relation exists between foreign conditions and the gastric-acid secretion, this latter should be affected in different ways and to different degrees. Very little is written about reflex unacidity in this connection. It is far more probable and may be regarded as a general law that under reflex influences a given stomach will secrete acid according to its capability and usual habit under direct irritation.

This same rule applies to gastric secretions in their relation to constitutional conditions. Except in cases of advanced cachexia or dyscrasias these secretions follow a more or less independent course. No relationship has been estab-

lished between gout, rheumatism, diabetes, tuberculosis, chlorosis, etc., and gastric acidity. In advanced stages of these conditions marked excess of acid may be exhibited in the gastric secretions, at times, so that no empirical conclusion can be drawn as to the condition of digestive function at any stage of these diseases. In those conditions, where, as a result of defective metabolism, a general acidity is supposed to result no influence whatever is exerted upon the acid secretion of the stomach. It may attain to any degree, plus or minus.

It is in the functional neuroses that the greatest degree of variability is exhibited in the gastric secretions. The reasons for this have never been determined. Why the emotional state should cause hyperacidity in one case, and hypoacidity in another, or the same variation at different times in the same individual, has never been solved. It is a problem so intimately connected with intracellular protoplasmic activity, that is, with life itself, that it has so far resisted all efforts at explanation, theory, or laboratory refinement. We know, however, that the tendency of the gastric secretions in these conditions is toward excess in the majority of cases. Fully seventy-five per cent. of so-called nervous dyspepsias are hyperacid conditions, and yet these occur in individuals a good percentage of whom comprise what the neurologists have called physiological inferiors. Why an organism which is physiologically inferior should be able to exhibit in such marked degree one of its most active defensive agents, either in the sense of digestion or in that of a purely chemical agent, is an enigma. Clinically, we may regard this tendency as another evidence of lack of inhibitory control, with which so many are born. Acquired neuroses seem to be losing ground. Heredity is the main feature in these conditions, so that, in this connection, excessive acid secretions may be allied with all the other uncontrollable muscular, sensory, and psychological phenomena associated with neurasthenia, psychasthenia, and hysteria. As these latter are aggravated by the lesser evils in life, by the daily small irritations, so is the tendency to hyperacidity increased by these same. Decided shocks cause cessation of secretion entirely. On the other hand, there seems to be no direct relation between depressed or irritated states of the nervous system and the gastric acidity. Intense nervous and mental depression causes no corresponding depression in the degree of acidity exhibited. On the contrary, the two states may show pronounced contrariety. The relation existing between the functional neuroses and gastric acidity displays the same independence which exists in purely reflex conditions and constitutional diseases.

In associated motor and secretory disturbances of gastric digestion the question of priority always arises. Which function is affected first? In a given case of hypersecretion, with food retention, which is the primary affection, hypersecretion or retention? It is not always possible to decide this question in an individual case, nor is it necessary to do so in advanced cases, for the conditions become retroactive in the course of time. Judging, however, from the natural tendency of the normal stomach to hypersecrete upon slight provocation, it is probable that in the majority of cases we have to deal with a primary excessive secretion and secondary retention. The tendency of every hyperacid stomach is to empty itself slowly for purely physiological reasons. The duration of pyloric contraction depends upon the neutralization period in the duodenum. If this is protracted by a high degree of acidity of the gastric contents, pyloric contraction will be prolonged. The resulting retention causes gastric irritation with increased secretion, and we have a vicious circle within the narrow limits of the stomach, pylorus, and duodenum. This explanation does not apply to all cases, but the principle of it is present in all cases. It is immaterial, in this connection, whether the primary exciting cause be remote or immediate—that is, physicochemical or psychoneurotic. Once the excess of acid is established the subsequent course of local development will be the same in most cases.

It has seemed advisable to review the general principles involved in hyperacid conditions of the stomach because the literature has become more or less confusing. The various descriptions of different types have served to obscure the underlying basis of biological facts which is present in all of them, and most variations are largely questions of degree. Chronic dyspepsia and hyperacidity are almost interchangeable terms, for excessive secretion is the feature of the great majority of our ordinary stomach troubles, whatever may be the operating causes.

TOP-MILK AND WHEY FOR INFANT FEEDING (ONE QUART OF MILK DAILY UP TO THE END OF THE FIRST YEAR); WITH SOME OBSERVATIONS ON MILK PURITY AND PRESERVATION.*

By RANSFORD E. VAN GIESON, M.D.,

Brooklyn, N. Y.

At this season of the year, with midsummer heat rapidly approaching and with it the conditions most favorable for bacterial growth and possible infection of the food of bottle-fed infants, the question of the best methods of artificial feeding with clean milk properly modified becomes one of the most serious import. It needs no reference to statistics to prove that the annual increase of the death rate among children under three years of age is almost wholly due to three factors: Heat combined with humidity, unclean milk, and improper feeding, producing intestinal infection and diarrheal disease. The climatic conditions are beyond our control, but much may be done to control the remaining factors. Since the days of Dr. Rotton Percy, who successfully led the crusade of the medical profession against swill milk from stall-fed, diseased cows, we have gradually but surely, through the strong hand of legal enactment, erected year after year barriers against the entrance of impure milk. That more has not been done is more the fault of the consumer than the producer. Stronger than laws to restrain the entrance of unclean milk and unwholesome cold-storage food, greater than periodical inspection of herds, is the will of the consumer educated to realize the death-dealing possibilities of germ-laden milk and food decomposed from prolonged cold

*Read before the Medical Association of the Greater City of New York, June 5, 1911.

storage. If the consumer tenders his money and demands its equivalent in untainted food and clean milk he will eventually receive it. The purveyor has his ear to the ground and when the popular murmur, united and intense, reaches him, the law will be obeyed and not evaded. There is no power stronger than the concentrated force of enlightened public opinion. Our duty then as medical men in all this matter of foodstuffs is a ceaseless campaign of education. Artificial feeding is based upon the use of milk of the greatest obtainable purity—the discussion of this question would be but a fatuous fallacy, if such milk is not obtainable. The problem is difficult enough with the purest and best milk; but when this is contaminated the solution is an impossibility by any method whatever. The prevention of the entrance of the grosser impurities is not difficult. The entrance of disease germs under the strict enforcement of our present laws should be an impossibility, barring a single portentous fact which is certainly very difficult to control. Coincidently with the summer heat, and remaining with us with more or less fatal activity, appears that most pestiferous member of the suctorial insect family, the common house-fly, long simply regarded as only a nuisance, but now known to be a dangerous foe. We are not far from the true facts when we venture to state that as transmitters of disease germs they are the most potent and difficult to combat. Born and bred in disgusting, decomposing, excrementitious products, perching on the dying and the dead, rioting in filth and corruption, feeding on germ-bearing material—omnipresent, of astounding fecundity, their feet shod with death-dealing bacteria—these winged assassins are active agents in food contamination, and against them there is but one defence, namely, a relentless war of extermination, and the destruction or making unfit as breeding places of the stable refuse. We have conquered the mosquito, we can also conquer the fly.

What simple cleanliness and cold can do in furnishing pure milk is strikingly illustrated by the following facts: "At the Paris exposition of 1900 there was an exhibit of dairy products under the care of Major Alford of the U. S. department of agriculture, which consisted of *fresh* milk and cream shipped from Illinois, New Jersey, and New York in hot weather (July), coming some 3,000 to 4,000 miles. The cream and milk were perfectly sweet a fortnight after being bottled, while the only other competitor was the French with a local supply which did not keep a day after reaching the grounds. In the Chicago national dairy show a sample of cream shipped over 1,000 miles was still sweet at the end of seven weeks. Cleanliness and cold were the only methods used in so wonderfully preserving the milk."

From whatever standpoint we may study the principles upon which successful artificial feeding should be based we eventually arrive at the main fact involved, and that is the gradual adaptation of the infant's digestive organs to a number of foreign substances by nature fitted for the nurture and growth of a lower animal. One cardinal principle must stand prominently in the foreground when we are dealing with cow's milk as a substitute for that of the mother, and that is that the ingredients of the former are practically altogether different from those found in human milk. This applies to all the substances except the water and the salts. Also, the milk of *any* animal in its living gland differs in some degree from dead milk in the test tube of the laboratory. Mechanical processes separating it into its supposed component parts, reassembling them in any desired proportion does not produce, even when the original proportions are preserved, the *same milk*. Something has disappeared. That something, clinical experience has proven, is essential to complete the full nourishing quality of the milk. It eludes the most elaborate chemical research. We therefore must arrive at the conclusion that milk, that most perfect of emulsions, is a very complex fluid about which much remains to be learned. Nevertheless, clinical experience and laboratory research unite in proving the basic fact upon which all successful modification depends in order to adapt it to the limitations of the infant's digestive ability —and that is, that, although animal milk contains substances apparently similar to those found in human milk, they are not chemically or even physically identical. This applies especially to cow casein. It is so radically different from human casein that it must be considered practically as a foreign body capable of nourishing an infant only after it has been modified and adapted to a stomach of feeble power designed by nature for an easily digested food. Cow casein readily coagulates into large, tough masses, insoluble armor-clad clumps, against which the feeble attacks of the gastric juice are impotent. Rebellion is at once proclaimed. The foreign intruder may be ejected by vomiting, and hostilities for a time are suspended. If not, it storms the weak fortress of the pylorus, passes victorious into the lower intestine, to become a culture medium of germs, a breeder of toxins, colics, diarrhea, and all the long train of evils which arise from forcing an unprepared foreign body into a stomach unable to digest it. Human casein coagulates slowly in very fine, soft flocculi, almost semifluid, pultaceous masses, easily digested.

To overcome and render innocuous this foreign body and yet preserve its nutrient properties is the main problem of milk modification. The central idea is to prevent its formation in solid masses. Cow casein is comparatively harmless if we can keep its particles separated. Our best method of doing this is the very simple one of dilution whereby we expose in a finely divided form much smaller quantities than the average amount of casein in mother's milk, to the digestive action of the gastric juice, and feeble peristaltic movement of the stomach. This is the condensed teaching of nearly a century of clinical experience. It is wise and safe to accept it, all study, analysis, comparison of calories to the contrary notwithstanding. Laying aside all theory it is sufficient to say that the stomach of the infant and that of the young calf are adapted by nature to their respective normal foods, and as we cannot, in changing from the calf to the infant, alter the organs we must modify the food to the organ. Dr. Louis Starr's comment upon this phase of the question is concise and appropriate. "We certainly should not sacrifice everything to chemical accuracy." The modern tendency is decidedly towards somewhat weaker dilutions than were used by our fathers, reducing the casein proteid to one-half per cent. and reaching slowly 1 per cent. at the end of the first month. If we thus lay the foundation, the main difficulty in modification is overcome, and having thus made casein digestible, subsequent success is assured; the proportions will remain nearly the same, the amount and frequency of the feedings varying according to the average capacity of the stomach.

The second form of proteid in cow's milk is the soluble one of *lactalbumin*. This is important and deserves special consideration. It more nearly resembles that of human milk than any other ingredient. It requires no modification. It is the chief ingredient of whey to the extent of 1 per cent. and is the most valuable asset in the top milk and whey mixtures, mainly because it enables us to give the needed amount of soluble digestible proteid with a minimum of casein—an achievement that insures success. The presence of lactalbumin in whey makes the latter one of the best diluents for casein that we possess—holding it in finer suspension, and preventing clumping in hard masses—thus obviating the use of weak cereal solutions until the amylolytic function is sufficiently developed to convert starch into sugar. Schlossman estimates total proteids in human milk at 1.56 per cent., of which 63 per cent. is casein and 37 per cent. lactalbumin. He considers that this large proportion of soluble albumin is of great help to digestion, since the infant obtains a considerable part of the nitrogen it requires in a form in which it can be directly absorbed, whereas casein has to undergo complicated changes before it is ready for absorption. In my preparatory formula for the first month, I have endeavored to approximate these proportions. It is estimated to contain 0.66 per cent. casein and 0.40 per cent. lactalbumin in total proteids of 1.06 per cent. The large percentage of fat in the top milk used in the formulas differs materially from that of human milk but is less troublesome to modify than the casein; when properly diluted with whey containing 1 per cent. lactalbumin, giving 2 per cent. to 3 per cent. fat, it produces no noticeable digestive disturbances. It is usually given somewhat in excess of what is really needed. Fat-free milk long continued, though containing over 6 per cent. of sugar, is sooner or later followed by unmistakable evidences of malnutrition. Dilutions of milk make it necessary to add some form of sugar to bring the total amount in the mixture from 5 per cent. to 6½ per cent. Here, as in almost everything else connected with infant feeding, there has been considerable dispute. Personally I have always used pure granulated white cane sugar. I am not prepared as yet to believe that cow lactose and human lactose are identical in composition or effect. It is contended vaguely and without sufficient proof that cane sugar is more liable to set up fermentative changes. It is also frankly admitted that it is often better borne than cow lactose. After using it for many years I have found no reason to change my views as to its superiority over cow lactose.

The lime water used must be the liquor calcis of the United States Pharmacopoeia. In combination with the lactose of the whey and the added cane sugar to 6 per cent., it is an anticoagulant of casein of feeble power and antacid.

The top milk used in the formulas is ten, twelve, fourteen, and sixteen ounces. The remainders are used for making the whey.

The percentages are calculated from 4 per cent. market milk, bottled and usually delivered before 6 A. M. Lowest measure of cream line from top of bottle 3⅛ inches, highest 3⅞ inches. Lowest price 9 cents per quart, highest 10 cents. The fat is figured from Chapin's middle column for 4 per cent. milk. The proteids are made somewhat lower than the estimates generally given. The writer agreeing with Holt (Judson and Gittings, p. 131) that they are usually figured too high.

TOP MILK PERCENTAGE.

Ounces.	Fat.	Proteid.	Lactose.
10	10	3.30	4.50
12	9	3.50	4.50
14	7.50	3.70	4.50
16	7	4.00	4.50

The whey is made from the milk remaining after the top portion is removed.

I have found Hansen's junket tablets the most convenient and cheapest form of rennin for this purpose. According to the maker they consist solely of rennin and common salt. One of these coagulates a quart of unsterilized, unpasteurized milk at a temperature of 98° F. in some eight minutes. When the surface of the milk begins to appear glossy and glistening and the whole mass moves from the side of the vessel when the latter is slightly tipped over, it is firm; it is then broken up in fine pieces with a fork, stirred rapidly for some twenty minutes, then replaced over the gas or alcohol stove, brought carefully to 130° F., and immediately removed. The curd gathers in a tough mass. It is now strained through two thicknesses of clean bleached cheese cloth, the curd being gently pressed, and when cooled to the temperature of the room is bottled and placed by an equal supply of top milk for the day's feeding. Thirty-two ounces of milk thus treated will yield 28 ounces and 2 drams of whey and smaller quantities proportionately the same. The whey must not be made from top milk, as it will give too much fat, and moreover this very valuable portion is needed—from 10 to 16 ounces for the child, according to its age.

One of the objects of this paper is to demonstrate how a baby may be successfully reared up to the fourteenth month on one quart of good fresh, clean bottle market milk. As the necessary safeguarding of the milk by proper sanitary surroundings and precautions at its source, the country farm, will entail, for a time at least, increased expense of production and consequent rise in price, milk for babies will become a somewhat precious fluid, and economy will become a necessity for parents of limited means. In cheesemaking, the curd is cut with a sharp knife into small strips or cubes, and the temperature is not raised above 98°. The whey drains off slowly and the curd contracting gradually retains nearly all the fat, the whey is clear and limpid. It will contain 1 per cent. lactalbumin and a minimum of fat, about 0.30 per cent. It is the so-called gravity whey, not adapted to the present method as it is lacking in fat. Whey prepared by my method yields a chylous-looking fluid, opaque from the presence of fat. From the remainder left after ten ounces are removed, the whey thus prepared from it will give 1 per cent. fat. The remainder from 12 and 14 ounces about eight-tenths of 1 per cent. I have calculated my mixture at eight-tenths of 1 per cent. fat to avoid unnecessary figuring. It is essential, however, that the whey should be prepared as nearly as possible according to the directions given and be decidedly opaque. This method also gives a maximum of whey from a given quantity of bottom milk and we need all we can get, especially when we reach maximum feedings of nine or ten ounces of the mixture.

An important and necessary feature in this process is the *inhibition* of the enzyme in the whey which may curdle the mixture if kept too long before feeding. Now an enzyme cannot be neutralized or saturated like acids and bases; when we consider that two or three ounces of an ordinary solution of rennin will curd effectually 1,000 pounds of milk at 98° F., we see at once that we are dealing

with a ferment that acts by contact, and any chemical that destroys its action will also make the whey unfit for feeding of infants. There is then no harmless method of inhibiting the action of the ferment except that of heat, but in doing this it is essential that we should not also coagulate the lactalbumin; when this happens it is of no more food value than so much sugar water. The lactalbumin must remain in solution; as such it is a valuable proteid, coagulated in suspension; it is changed into something, we know not what, but we may infer that insoluble, it is about as indigestible as the casein proteid. Monti heats the whey to 155° F. to destroy the lab ferment, cools and strains through a silk cloth. It is then mixed with one or two parts of milk put in sterile bottles and pasteurized at 158° F., cooled to 50° F., and kept at this temperature until used. No doubt the enzyme is destroyed and unless great care is observed, to some extent also, the lactalbumin which should be kept in solution. A clear limpid gravity whey when heated grows opaque at 158° F., at 160° F. it coagulates.

Whey prepared by my method at 130° (135° maximum) *inhibits* the enzyme sufficiently for all feeding requirements. Its total destruction (at 145° F.) is not necessary, as the whey and top milk are not mixed until just before feeding. When a traveling supply is needed sufficient whey is prepared at 135° F.; the top milk, an equal quantity is heated to 140° F., placed in separate bottles, and used as required. On general principles, with any system of feeding, it is better to keep the ingredients separate until feeding. With this method it is *imperative*.

Addition of Starch.—This may be coarsely ground wheat, barley, oatmeal, or granum. I have usually used the latter. Its analysis (Leeds, quoted by Judson and Gittings) gives, in percentages: Water, 8.38; albuminoids, 13.13; fat, 1.40; starch, 76.11; soluble carbohydrates, 1.80; ash, 0.39.

It has the advantage of being easily prepared, requires no straining, and has about the same value as wheat. Modern authorities on infant feeding all agree that there is no rule more important than that which fixes the time and regulates the amount of starch to be given. Some prefer to wait until the amylolytic function is well developed, others begin when it is sufficiently developed to convert *small quantities* into sugar. The experiments of Korowin in 1873, confirmed by Shaw in 1904, prove that young infants can convert starch in ½ per cent. solutions. Rotch says that starch should not be given before the eleventh or twelfth month. Between these two extremes there is a safe period when it can be made available as a nutriment in small amounts, and that is, in the healthy infant, at about the sixth month. It must be given tentatively and increased very gradually in the same watchful manner that we accustom the child to live and thrive on cow casein.

The cereal solution is made by adding four rounded teaspoonfuls of granum to one pint of water in a quart agate-ware open boiler and boiling twenty to thirty minutes. An indicator is hung over the edge of the boiler showing the height of the water before boiling. After twenty minutes the water will be reduced nearly one-half. Water is now added to the pint mark, brought again to the boiling point, removed, and bottled when cool. This makes a 4 per cent. solution, a dram of which will contain about 2½ grains.

The formulas constructed upon the preceding principles are measured in drams. They are *initial, preparatory, intermediate,* and *permanent,* designed to feed a child all it may require to the end of the year or fourteenth month.

Initial Formula.—First to third day: Whey, 6; boiled water, 3; lime water, 1; total, 10 drams. Sugar, 20 grains = 1/3 teaspoonful. Contains: Fat, 0.48; lactalbumin, 0.60; sugar, 6 per cent.

Preparatory Formula.—Introducing casein from 10 ounces top milk; to end of fourth to fifth week proportions increased as may be needed: Top milk, 2; whey, 4; boiled water, 3; lime water, 1; total, 10 drams. Sugar, 1/3 teaspoonful, or 20 grains. Estimated to contain: Fat from top milk, 2; fat from whey, 0.32; total fat, 2.32 per cent. Proteid from top milk, 0.66; lactalbumin from top milk, 0.40; total protein, 1.06 per cent. Sugar (20 grains), 6 per cent. Total solids, excluding salts, 9.38 per cent.

Permanent Formula.—At the second month the child having been accustomed to the casein proteid, tempered and attenuated by the soluble lactalbumin, we begin with the basic formula consisting of equal parts (drams) of top milk, whey, and boiled water, to which is added lime water from 6 to 10 per cent. and sugar 6 per cent. The proportions will remain the same. The percentages will vary as we pass from ten ounces to twelve, fourteen, and sixteen of the top milk, the fats slightly decreasing, the proteids increasing. At the sixth to eighth month starch is added gradually to balance the decrease in fats. The lowest basic formula will be ten drams, the highest eighty drams, or ten ounces.

BASIC FORMULA (IN DRAMS).

Top milk	3		24
Whey	3		24
Boiled water	3	× 8 =	24
Lime water	1		8
Total	10		80

The lime water will vary when units are added to the equal parts. Multiplying *all* the parts will of course give 10 per cent. In order to prevent confusion I usually give the mothers feeding cards calculated for six to eight weeks from their last. The basic formula, total drams multiplied by 2, will give total grains of sugar to be added to bring the mixture to 6 per cent. total sugar. For domestic feeding we estimate an even teaspoonful dry granulated sugar at sixty grains or one dram. The results are sufficiently accurate. It is estimated to contain:

Ten Ounces Top Milk.—Fat from top milk, 3; fat from whey, 0.24; total, 3.24 per cent. Proteid from top milk, 0.99; lactalbumin from whey, 0.30; total, 1.29 per cent. Sugar (20 grains), 6 per cent. Total solids, excluding salts, 10.53 per cent.

At about the fifth month we will be feeding seven feedings of 9-9-9-3 or 12-12-12-4, or from four to five ounces, and ten ounces will not suffice, so we pass to twelve ounces, and after this time rarely give night feedings. The estimate of this formula shows it to be slightly decreased in fat and increased in proteins, or casein.

Twelve Ounces Top Milk (sixth to ninth month).—Fat from top milk, 2.70; fat from whey, 0.24; total, 2.94 per cent. Proteid from top milk, 1.05; lactalbumin, 0.30; total, 1.35 per cent. Sugar (20 grains), 6 per cent. Total solids, excluding salts, 10.29 per cent.

The feedings will be five to six ounces six times daily giving 12-12-12-4 = 40 drams, or 15-15-15-5 = 50 drams.

We can now introduce a fraction of 1 per cent. of the 4 per cent. granum solution by substituting one dram for one of the boiled water. Top milk, 15; whey, 15; boiled water (14 + Granum Sol. 1), 15; lime water, 5; total, 50 drams. Sugar, 1½ teaspoonfuls.

In six feedings the total granum is 2½ × 6 = 15 grains, or 1/12 of 1 per cent.

These additions of one to two drams are continued so long as no intolerance is noticeable, until all the boiled water is replaced by the granum solution, when the percentage will be 1.20, which is the limit of the basic formula. This happens normally at about the fourteenth month, when the feeding capacity and needs of the child will begin to exceed the quart allowance and it may be safely weaned. When two bottles of milk can be afforded there are two intermediate formulæ having well balanced proportions of fat and proteids that can be introduced after the preparatory formula, estimated from ten and twelve ounces of top milk. With one bottle we have to pass on to the fourteen and sixteen-ounce formula, adding more granum water in place of boiled water to balance fat decrease, say 0.80 per cent.

Basic Formula, 14 Ounces Top Milk.—Fat from top milk, 2.25; fat from whey, 0.24; total fat, 2.49 per cent. Proteid, 1.11; lactalbumin, 0.30; total, 1.41 per cent. Sugar, 6 per cent.; starch, 0.80 per cent.; total solids, excluding salts, 10.70 per cent.

Basic Formula, 16 Ounces Top Milk.—Fat from top milk, 2.10; fat from whey, 0.24; total, 2.34 per cent. Proteid, 1.20; lactalbumin, 0.30; total, 1.50 per cent. Sugar, 6; starch, 1.20 per cent. Total solids, excluding salts, 11.04 per cent.

In the sixteen-ounce formula *all* the boiled water has been replaced by the 4 per cent. granum solution giving the highest starch percentage and total solids percentage.

Intermediate Formula, 10 Ounces Top Milk.—Top milk, 3; whey, 4; boiled water, 2; lime water, 1; total, 10 drams. Sugar, 1½ teaspoonfuls.

Fat from top milk, 3; fat from whey, 0.32; total fat, 3.32 per cent. Proteid, 0.99; lactalbumin, 0.40; total proteid, 1.39 per cent. Sugar, 6 per cent. Total solids, excluding salts, 10.71 per cent.

Intermediate Formula, 12 Ounces Top Milk.—Same formula. Fat from top milk, 2.70; fat from whey, 0.32; total fat, 3.02 per cent. Proteid, 1.05; lactalbumin, 0.40; total proteid, 1.45 per cent. Sugar, 6 per cent. Total solids, excluding salts, 10.47 per cent.

Results.—Of some ten cases, all but one were typical examples of malnutrition. Three are weaned. One after having entirely recovered from all digestive disturbances contracted whooping cough and died of broncho-pneumonia at the end of the fifth month. Six are still under observation; from these I select two, one of medium severity and the other requiring very careful treatment.

Medium severity, simple malnutrition.—Mrs. B.'s adopted child. Taken from a home when four months old; had been fed on modified milk from birth, but did not grow well, suffered from colic and diarrhea and occasional vomiting. Mrs. B. gave it commercial artificial food without improvement and it seemed to grow weaker and worse. Colic and diarrhea remained about the same. The child was brought to me at five and one-half months. I prescribed the preparatory formula with excess of whey with top milk from eight ounces. In two weeks the basic formula. It is now sixteen months old, taking three nine-ounce feedings and two meals of bread-and-butter pap with equal parts of whey and twelve ounces top milk.

Mrs. S.'s eighth child.—Her first born is living, six intervening children have all died between the third and fourth month. All were born plump and well, averaging seven to eight pounds at birth; two took the breast for two months, four for five weeks, when milk dried up. All were given artificial commercial foods and modified milk, but all food disagreed; to use her own words, "they cried almost constantly and everything ran through them." This last child was not put to the breast and the best commercial artificial food was given with the same symptoms—colic, diarrhea, and emaciation. At the fifth week it was brought to me in a pitiable condition. It seemed to me that the only prescription fitted to such a case was human milk from a healthy wet nurse. I gave top milk, 2; whey, 4; boiled water, 2; lime water, 1, from six ounces top milk five drops cod liver oil between feedings and inunctions of the same twice daily. There was slight gain in a week. In a month there was a decided gain. I then gave basic formula from ten ounces top milk. At the present time (June, 1911), after six months, it is taking the basic formula from twelve ounces top milk. The cod liver oil inunctions are continued and if there is no tuberculous infection we may make a favorable prognosis. It is the only child of the seven that has lived beyond the fourth month.

The third case has been under my personal supervision since birth, April 6, 1910, face presentation and instrumental delivery followed by partial facial paralysis and rather feeble suction. Breast milk, none. Put immediately on initial formula third day, preparatory ten ounces top milk; starch at six months; is now taking top milk, 22; whey, 22; granum solution, 22; lime water, 7 drams (total, 9 ounces) × by five feedings = (forty-five ounces daily ration), with a nibble of stale bread between feedings. It has never had the slightest digestive disturbance. It measures thirty inches, weighs twenty-five pounds, and is well and happy.

To sum up: (1) The central idea of these formulæ is gradual adaptation of foreign substances to weak digestive powers; (2) the great value of lactalbumin solution as a diluent and nourishing soluble protein; (3) the necessity of preserving it *intact* by using *moderate temperatures* to *inhibit* the action of the enzyme; (4) to preserve as nearly as possible the proportions of one-third lactalbumin to two-thirds proteids.

Finally, to anticipate some objections: (1) That it is too complicated for domestic use. Answer: It is more complicated in theory than in practice: one lesson usually suffices. The mothers follow their cards and make few errors. (2) It is expensive and troublesome. Answer: No; the chief expense is clean pure milk. This is essential with any method employing milk. The expense is one dairy thermometer, 25 cents; a two-ounce graduate, 30 cents. The remaining implements are found in every household. No trouble is too great that may save an infant's life.

94 Kent Street.

Experimental Influenzal Endocarditis.—Porrini produced endocarditis in rabbits by means of injections into the veins of the ear of mixtures of influenza bacilli and toxins with an indifferent powder (Ribbert's method), or with adrenalin (de Vecchi's method).—*Gazzetta degli Ospedali.*

THE SIGNIFICANCE OF FEAR IN MENTAL DISEASES. REPORT OF A CASE WITH CLAUSTROPHOBIA.

By MAX A. BAHR, M.D.,

INDIANAPOLIS,

CENTRAL INDIANA HOSPITAL FOR THE INSANE.

The condition of fear has not until recent years been given serious consideration in psychiatric practice. It occurs either as an emotional state or as in the various phobias in the form of compulsory concepts or ideas. The fear of emotional origin may occur at times without any kind of accompanying physical perception, at times it is associated with the greatest multiplicity of sensations. The latter is generally more frequent. Very often it is joined with a painful feeling of oppression in the region of the heart which has been designated by Professor Ziehen of Berlin as *Præcordialangst* (præcordial fear). Many patients complain of constriction in the neck accompanying the fear, others of a feeling of uneasiness in the abdomen. Others complain only of a feeling of unrest which at times appears in the entire body, at times in the legs, and at times in the arms. According to the seat of perception they are designated as præcordial fears, thoracic fears, abdominal fears, etc. At times the localization of fear is also determined by accidental coexisting sensations or pains which have already existed long before the appearance of the fear. In those cases where accompanying perceptions are entirely wanting, the patients state either that the fear is "seated everywhere," or it is a "mental fear," or finally they also locate their fear in the head in spite of the absence of the accompanying perceptions. There has been much dispute regarding the relation of fear to the accompanying perceptions mentioned, and it has even been designated that these accompanying perceptions acted directly as the cause of every fear, and designated for example especially the præcordial fear directly as a vasomotor neurosis of the heart. This conclusion is erroneous from the fact that the accompanying perception can at times be entirely wanting in profound fear. Primarily fear, like all normal and pathological emotions, is much more frequently of cortical origin. It more frequently and more intensely than other emotions exerts an influence upon the striated and unstriated musculature of the body. This manifests itself in the so-called movements of fear, the apprehensive rubbing of the hands, and the to-and-fro movements of the limbs as is so characteristic in the melancholia of involution. The respiration is frequently altered during the fear of the patient as he breathes more rapidly, and thus arises the accompanying perception of "thoracic fear." Finally still more important is the influence of fear upon the circulation. The peripheral arteries undergo a stronger contraction, the heart action becomes accelerated, irregular and less forcible. Consequently here arises the "paroxysms of fear" and the "cardiac unrest," of which so many patients complain.

Fear can also induce a condition of motor inhibition resulting in a state of complete catatonic stupor. Why it produces in one case a motor inhibition and in another an agitation has not yet been fully explained. In not a few cases the influence of fear upon the individual varies at different times, inhibition and agitation alternating with each other. Fear also induces so-called secondary delusional concepts; the patients seek in a manner an explanation of the fear, and consequently the delusional ideas of having sinned, of impoverishment, of being incurably ill present themselves as welcome attempts at explanation. In rare cases there also occur secondary hallucinations with corresponding content. Such are the fears of emotional origin in counterdistinction to the various phobias which make their appearance in the form of compulsory ideas. These phobias are always characterized by the sudden appearance of pronounced anxiety in connection with the general idea of fear. When subjected to them, patients may suffer from palpitation of the heart, become pale, tremble, have cold sweats, nausea, faintness, polyuria, weakness in the legs, and finally may even lose control of themselves and collapse.

The conditions in connection with which such attacks of fear arise are varied, yet there are some forms which recur with notable regularity. Thus there is the fear of open or closed places, fear of high places, fear of men or women, fear of crowds and of solitudes, fear of animals, fear of insects, fear of darkness, fear of accidents, fear of fire, fear of travel, and in fact fear of anything. There is no end to the absurdity of acts which may be occasioned by these persistent ideas of fear. Those that possess the fear of riding on a train find no pleasure in traveling, those that have fear of closed places do not enjoy going to church, and generally always sit near the door ready to fly at the first sign of danger. Various fears may also develop in connection with the occupation of the patient; for instance, barbers sometimes suffer these attacks whenever they see a razor, or telegraphers when they catch sight of their instruments, which finally necessitates giving up the occupation. Among women, especially, there occurs the fear of dirt, contagion, or infection. The countless bacteria always present in the air are the chief source of annoyances. The patients are always complaining of bad air and are always throwing open the windows. Books are especially avoided as a possible source of contagion. In patients with fear of injury they will throw away all needles in the house, or they will no more wash windows for fear that the glass might break and cut them. The intellect in these cases is not only undisturbed, but may be unusually good. Patients exhibit throughout a pronounced feeling of mental illness and frequently a clear insight into the morbidity of the individual symptoms.

The more common of the various phobias as classified by Beard are as follows: Claustrophobia, fear of narrow or closed places; agoraphobia, fear of open places; astraphobia, fear of lightning; monophobia, fear of being alone; pathophobia, fear of disease; mysophobia, fear of contamination; siderodromophobia, fear of railroad travel; acrophobia, fear of being at a high height or looking over precipices; thanatophobia, fear of death.

It is to be emphasized that the phobias in question are not normal fears, based, as normal or natural fears are, on some reasonable justifying experience. A reasonable and justifiable normal fear of lightning might arise after the experience of having been at some time in a house struck by lightning. Other fears, such as the fear of riding in a buggy after having been in a runaway, or the fear of a voyage at sea or railway after a frightful shipwreck or railway accident, is a more or less

natural or reasonable fear, as the fear of hoodoos and ghosts are among the superstitious or those accustomed to ghost stories and tradition of goblin visitation, etc. These fears do not require a warped brain for their lodgment or entertainment, though the weakened brain may be more vividly impressed and markedly swayed by them. The morbid phobic symptoms to be of diagnostic value must be groundless in their inception or continuance so far as influences external to the brain are concerned. They must be of intercerebral and not of extraneous origin. They must proceed from a morbid state of the brain and not from properly exciting external causes. They must be fears peculiar to the individual under peculiar circumstances of cerebral disturbance and not fear common to others and due to causes that naturally cause alarm and frighten. The fear, for example, of microbic infection from distrust of perfect cleanliness in an establishment, in a barber, in a cook, etc., may be normally founded. There is a normal, natural, scientific and medically legitimate mysophobia which must be differentiated from the morbid fears of an abnormal brain.

These various phobias have so frequently been complicated with neurasthenia that all such cases have at times been regarded as such. This, however, is not the case, as not a few cases exist in which all neurasthenic symptoms are wanting. Such is the case to be described below. It is to be emphasized that these various phobias only represent a symptom and that they may be found in various psychoses, as in melancholia, in the beginning stage of dementia paralytica, at times in the course of paranoia, furthermore in hysteria, etc., and especially in neurasthenia. Hereditary taint is exceedingly frequent and occurs in about 80 per cent. of the cases. The outbreak occurs most frequently at the time of puberty. Occasionally the first phobias already present themselves at childhood. Now and then the beginning of the disease takes place at the climacterium. Very frequently it deals with individuals who at times already before the phobias, manifested an abnormal love of order, an extreme conscientiousness and indecision, and a peculiar deficiency of self-confidence. Masturbation, nicotine abuse, alcoholic excesses, intellectual overexertion, physical fatigue, anemia, accumulated emotional excitations frequently are superadded upon the hereditary endowment. Further satisfactory etiological research has still to be made in regard to this type of mental condition. The presence of these phobias generally signifies an unfavorable prognosis. Long intermission may occur, but relapses are most inevitable. Usefulness is seriously impaired, but patients may continue for many years to be self-supporting. Exclusive of the chances of suicide, the average duration of life is not specially shortened. Transition into secondary dementia also does not take place. Such a condition is at times simulated, in that the patients after many years finally become weary of the struggle and mechanically give way the whole day to their morbid fears. Because of this, other interests and other emotions in the patient are lost. It is sad to say that many of the patients become addicted secondarily to alcoholism and morphism after they have once learned the otherwise wholly transitory favorable action of the alcohol or the morphine upon these morbid fears. Apart from the hereditary susceptibiliy and instability of the cerebral centers, no definite pathology can be assigned. These various phobias, as already stated above, may occur in many forms of insanity, but they do not constitute the gravamen of the mental disease, as is the case of fears which originate in the form of compulsory concepts or ideas. The following is a case with pronounced and persistent symptoms of claustrophobia: A male, age 48 years, was admitted to the Central Hospital the following dates: June 7, 1895; June 7, 1910, and again on September 21, 1910. His family history was negative excepting that his brother died a rather mysterious death in which there was suspicion that he had committed suicide. There was nothing unusual in the early history of the patient. He was ill but very little as a child and was an average pupil at school. It was stated that as a young man he was somewhat more seclusive than his associates, that he cared very little for company, and that he would rather be alone. Married at the age of 23 and has three children living, all in good health. One child died at birth and the mother died at the same time. This has worried the patient a great deal, and as he states: "I have never had a cheerful day since." This was about seventeen years ago, or about one year previous to his first admission to this institution. No history of alcoholism, but he has used tobacco somewhat excessively. At each admission of the patient the entire psychical process has been dominated by the feeling of fear that he will be caught in a burning building or that he will be killed by the roof of a building falling on him. He has lived in this state of fear almost constantly since 1894. He has a complete insight into his condition. Says that he realizes the fallacy of his belief but cannot rid himself of this morbid fear. "At times this fear will leave me and I will feel better, but I know that I have not been entirely well since leaving the institution the first time." Question. Are you insane? "I am not insane, but I know that I act queer, but I can't help it." On several occasions the patient has had hallucinations during the course of the illness, but they have not materially influenced the disease. His emotional state has been chiefly one of depression and anxiety in consequence of these morbid ideas. "I would have to carry out my queer ideas or I would never have peace of mind." The patient was a farmer by occupation and frequently when these compulsory ideas of fear would come over him, that he would never be able to come out of a building alive, he would avoid entering the same and for weeks and months at a time he would sleep out in the open. He would also take his meals outdoors for the same reason. Later he also developed the idea that people were going to kill him and he secluded himself from everyone for weeks at a time. He had no systematized paranoid ideas of persecution nor was there any plot to kill him. "Just this feeling of being afraid and that someone might kill me." Also developed compulsory ideas that he must count the trees and their branches as he walked along the roadside. Frequently when these ideas came over him he fought against them, but he would never have peace of mind until he gave in to them. Question: Have you ever thought of suicide? "I have frequently thought of it, but I don't believe that I would ever attempt it." "Doctor, just send me away, a thousand miles away from all civilization and I will be all right." "Afterwards, when I feel better, I fully realize that these are only imaginations on my part." There is absolutely

no dementia present. Patient answers all questions correctly within his educational sphere, and is also well orientated as to time, place, and persons. The patient's abnormal action and conduct has always been in consequence of his morbid fears which would crowd themselves upon him and over which he had no volitional control. Physical examination was negative excepting that he was troubled considerably with insomnia. Examination of the urine at various times showed considerable indican to be present.

AUTOINOCULATION;

ITS PRACTICAL APPLICATION IN THE TREATMENT OF VARIOUS INFECTIONS AND AS A SUBSTITUTE FOR BACTERIAL VACCINES.

By MARTIN J. SYNNOTT, A.M., M.D.,

MONTCLAIR, N. J.

It has been demonstrated at various times by Sir Almroth E. Wright that in active immunization there are three great agencies by which immunizing responses may be evoked in the human organism: (1) The inoculation of bacterial vaccines; (2) artificially induced autoinoculation, and (3) spontaneous autoinoculation.

Autoinoculation means the escape of bacteria or their products from the focus of disease into the adjacent lymph or blood stream. The result of such an escape is usually to increase the opsonins and other bacteriotropic substances in the blood by stimulation of the machinery of immunization. In this way Nature endeavors to cure or relieve the infective process.

When a patient fails to recover from a bacterial infection this is due (1) to excessive autoinoculations, causing a profound or permanent "negative phase," with lowered resisting power in the blood, making possible the rapid extension of the disease processes; (2) to an inadequate or tardy immunizing response; or (3) to the fact that the infective bacteria occupy a nidus so sheltered from the by-circulating blood that the antibacterial agencies (opsonins) in the blood do not have free access to them, and thus phagocytosis is interfered with.

Immunizing responses may be evoked artificially by hypodermic inoculations of bacterial vaccines, which are either derived from (autogenous), or correspond to (exogenous), the infecting microorganisms. In strictly localized infections we have generally no autoinoculations, and consequently no natural immunizing responses. It follows, therefore, that all such infections are preeminently adapted to treatment by therapeutic immunization with appropriate bacterial vaccines.

In generalized infections, on the other hand, Nature is producing a succession of autoinoculations, because bacteria or their products are being set free in the organism from the infected area, and these in turn evoke immunizing responses in the organism, as a result of which the antibacterial elements (opsonins) are increased in the blood. In this type of infection vaccine inoculations may do harm, except in the hands of an expert immunizator.

Spontaneous and artificially induced autoinoculations are destined to prove important factors in the treatment of many diseased conditions, in which vaccine inoculations are refused or are contraindicated, and an interesting field for experimental therapy along these lines is thus opened to the intelligent and observant physician. Moreover, it is important in treating all infectious diseases to find out if possible, before resorting to bacterial inoculations to produce active immunity, what the body itself is doing and to what extent extraneous circumstances such as exercise, massage, motion, Bier's apparatus, etc., may influence these attempts on the part of the body.

In most active infectious disease processes, such as febrile phthisis pulmonalis, spontaneous autoinoculations are almost continually taking place, even though the patient may be at rest. Such patients are, according to Wright, living in a succession of negative and positive phases. The degree of autoinoculation is in proportion to the activity of the disease. There are other cases in which autoinoculations cease when the patient is at rest, but reappear after any movement sufficient to stir up the disease foci (such as exercise, coughing, talking), and to let loose into the general circulation either the products of the microbe or the microbe itself. This fact explains the high or variable opsonic index often found in acute phthisis, a phenomenon also observed in other diseases after local stimulation.

This variation in the opsonic index may be made use of for diagnosis and in skilled hands is a valuable sign. Thus in cancer of the tongue prolonged reading may influence the opsonic index curve to Doyen's *Micrococcus neoformans,* enabling us to differentiate between malignancy and syphilis. Again, as pointed out by Matthews, an obscure joint swelling may be so treated by massage or Bier's bandage as to cause an increase of the local circulation when, if tubercle bacilli are present, a variation in the tuberculoopsonic index will occur; or if the gonococcus is the cause a variation will occur in the opsonic index to the gonococcus. A variation distance at least equal to three-tenths of unity will be positive proof that tubercle is the cause of the swelling or at least is present as a secondary infection. Thus a variation from 0.8 to 1.10 would be considered diagnostic. In suspected tuberculous peritonitis deep kneading of the abdomen may be resorted to. In suspected phthisis active exercise for one-half hour may induce the required autoinoculation. An enlarged lymphatic gland may be carefully massaged or stirred up by hot fomentations, and the blood examined before and after.

In other words, when a focus of infection is stirred up by massage or passive motion or exercise or in any other way, or if the blood by active or passive hyperemia is forced into the lesion in increased amount, we have variations in the opsonic index which indicate that something has occurred in the body to elicit a protective response against the organism to which the index varies. Passive hyperemia induced by Bier's bandage thus becomes a valuable diagnostic measure when combined with the opsonic index. The bandage is applied for one-half hour and blood specimens obtained before and at varying times after. The opsonic indices are then estimated against the suspected organisms, and whichever organism shows a variation from the normal in the index is the probable cause of the disease. If the index is low before the application there will be a rise and later a fall. If the index is high at the start there will be a drop after the application, following by a rise. This technique in the hands of an experienced opsonist is one of the most delicate and accurate that can be applied.

It must be borne in mind, however, that general

and indiscriminate massage of infected joints or lymphatic glands is not advocated, each being weighed on its own merits. At St. Mary's Hospital Bier's method of passive congestion is constantly used as a means of producing a diagnostic autoinoculation, and cautious exercise of a previously immobile joint has been shown by Matthews and others to give valuable indications as to the nature and activity or otherwise of any infection, if opsonic indices before and after movement are taken.

Spontaneous and artificially induced autoinoculations have been made use of by skilled immunizators not only for purposes of diagnosis, but also as agents to bring about a cure. The treatment used to stimulate the infected area, whether it be exercise or massage, not only produces an inoculation with effects similar to those produced by an appropriate bacterial vaccine, but by increasing the local circulation through and about the focus of infection causes an increased outflow of lymph, whereby a greater quantity of protective substances is carried into the infected areas and thus healing tends to result.

Bier thought when he devised his apparatus that he did good by flushing away toxins from the joints of his patients by inducing hyperemia; whereas according to Wright he is in reality inducing an autoinoculation each time he uses his apparatus by letting loose into the general circulation live bacteria or their products from the infected area or joint.

The successful application of this theory depends upon the judgment of the physician as to the proper amount of massage, Bier's bandaging, or exercise applicable to a given case. Thus in the case of a badly or acutely swollen and inflamed joint our treatment must be very gentle and for a short time only; while in chronic inflammations and subacute conditions the treatment must be more frequent and more prolonged if beneficial results are to be obtained. This fact explains why certain tuberculous patients improve under moderate periodic exercise or massage, followed by a period of complete rest, whereas the patients who overexercise or who take exercise at too frequent intervals do not improve or may even be harmed. This is demonstrated experimentally by estimating the opsonic index before and after Bier's bandaging in the one case and exercise or massage in the other, and bears out the analogy to an overdose or to too frequent doses of a vaccine doing harm where bacterial inoculations are employed.

Very complete experiments have been undertaken and interesting reports made as to the part played by autoinoculation in pulmonary tuberculosis by Dr. M. S. Paterson, medical superintendent of the Brompton Hospital Sanatorium at Frimley, near London, England, and Dr. A. C. Inman, superintendent of the laboratories of Brompton Hospital for Consumption and Diseases of the Chest, London.* Their observations convince them that many patients suffering from tuberculosis of the lungs are benefited, and many others cured by systematic exercise and graduated labor. Experiments with the patient's blood and determination of the opsonic indices before and after exercise or work have enabled them to demonstrate that the work or exercise causes an autoinoculation of the patient, which is indicated by the rise of temperature. This is followed by a period of improvement, if the exercise was of the right amount, corresponding to the negative and positive phase following a vaccine inoculation. It frequently happens that patients who fail to improve on a certain grade of work do improve on harder work, on the theory that the harder work gives rise to an autoinoculation, whereas the lighter work fails to do so. In other words, the work must be adapted to the exact medical condition of each patient. The examination of the blood with determination of the opsonic index is an essential element of success in the treatment of cases in this manner, because by it we are enabled to pick out the patient who is autoinoculating himself properly as indicated by a normal or high index, and also patients who from excessive autoinoculations have continuously low indices.

In Dr. Paterson's scheme the work-exercise is very carefully graduated, beginning with gentle walking and ending with concrete making, excavation work, etc., the last grade being full navvy work, almost as severe as it is possible for even a healthy individual to accomplish. The treatment has been remarkably successful. The essentials for success are (1) The most careful graduation of the exercise, and (2) close observation of the temperature chart, work being at once stopped if fever appears. In this way we produce carefully graduated, artifically induced autoinoculations. The autoinoculation induced by the stimulus of exercise and its systematic graduation may with the aid of the opsonic index be regulated with scientific accuracy and results obtained most certainly and accurately.

The index is important because it saves time by determining within a week whether the patient is fit for harder work, when clinically we might hesitate to come to such a conclusion. Many patients who do not improve on light work show marked improvement on harder work, and even patients who overexert themselves, thus getting an overdose of an autoinoculation, if they are kept at rest for a few days, do themselves no lasting harm. The difficulty is to determine the correct amount of exercise and the proper intervals of work and rest. The temperature must be carefully watched and the above treatment applies only to patients whose temperature does not exceed 99° F.

While the opsonic index, when estimated by a careful and well trained worker, is the best and safest guide, many successful immunizators have learned to dispense with it, except as an occasional confirmatory control. The careful and correct interpretation of the clinical signs becomes then a sufficient guide to the experienced inoculator.

The thorough comprehension of the phenomena of autoinoculation enables us to explain many clinical problems hitherto obscure. An intelligent understanding of its *modus operandi* will be a valuable aid to the general practitioner. Thus in all active febrile infections autoinoculations may be excessive, and measures to control them, such as ice, absolute rest in bed, etc., are imperatively indicated. Poultices or other measures to induce increased circulation through the diseased focus may do serious harm in generalized infections by causing still further escape of bacteria or their products into the circulation. For example, in a severe pneumonia with hyperpyrexia, fomentations to the chest may induce excessive autoinoculation and retard recovery by causing a prolonged negative phase.

In chronic conditions and in all non-febrile con-

The Lancet, January 25, 1908.

ditions, in which bacterial vaccines are indicated, much good may be accomplished by periodic autoinoculations, artificially induced by exercise, Bier's apparatus, massage, or any of the various measures at our command for the production of an increase of circulation through the infected part.

Unless the protective substances in the circulating blood have free access to the infected area, a high opsonic index may not necessarily react in the direction of a cure. The walls of an old sinus with a poor blood supply by reason of pent-up discharge, due to obstruction to outflow, or coagulation, offer the infective microorganisms a highly suitable nidus in which to multiply. Again the contents of an infected cavity, whether it be the peritoneum, pleura, or an ordinary abscess, may be low in protective substances while the by-circulating blood may contain an excess. Lymphogogues are indicated in such cases. Flushing the sinus with a solution containing 4 per cent. of sodium chloride and 1 per cent. of sodium citrate in sterile water promotes by its hypertonicity increased osmosis through the sinus walls, and a more copious flow of lymph ensues. Inasmuch as the sodium citrate prevents coagulation, the lymph, rich in protective substances, will find its way to the surface uncoagulated. In the case of a cavity, on the other hand, drainage is followed by the introduction of fluids from the blood, containing an excess of protective substances, and the cavity is quickly healed.*

The same precautions must be observed against inducing an excessive negative phase from an autoinoculation as are followed in using vaccines.

In comparing the respective advantages of autoinoculation and inoculations with bacterial vaccines as a means of treatment in bacterial infections, we must not forget Wright's warning that in the former method we use unmeasured doses of living cultures and therefore it must be uncertain and can never be altogether dissociated from risk.

SOME METHODS OF PHYSICAL EXAMINATION IN THE DIAGNOSIS OF SURGICAL DISEASES OF THE KIDNEY.†

By HAROLD NEUHOF, M.D.,

NEW YORK,

SURGEON TO THE HEBREW INFANT ASYLUM; ASSISTANT SURGEON TO THE NEW YORK NEUROLOGICAL INSTITUTE; ADJUNCT ADMITTING PHYSICIAN TO MOUNT SINAI HOSPITAL.

For the past two years the large number of patients suffering from renal affections that have been examined in the Admitting Department of the Mount Sinai Hospital have been studied in order to determine whether by some methods of physical examination not generally employed, vague and obscure symptoms complained of by patients could not more frequently be connected with surgical disease of the kidney‡ as the cause of the symptoms. It is hardly necessary to state that when a patient first appears for examination and suspicion of surgical disease of the kidney is aroused, the more refined methods of renal examination, cystoscopy, ureteral catheterization, etc., are not at once employed. It is, therefore, of importance that at the first examination of the patient one should have at his disposal methods of physical examination of the kidney which may be termed gross methods. It is with these methods that we are here concerned.

I. *Inspection.* Regarding the ordinary methods of physical examination of the kidney—inspection and palpation—there is little to add to what is generally known. It is, however, of interest to observe that when one kidney is the subject of an acute affection, the corresponding lumbar and abdominal regions remain almost or quite immobile, whereas there is normal respiratory mobility on the opposite side. If the patient be placed on his back in a light so cast that the lateral chest and abdominal walls are in shadow, we have sometimes observed, in such affections of the kidney as acute pyelonephritis, for example, that the shadow overlying the lateral abdominal region moves with respiration on the normal side, but remains immobile on the diseased side. This phenomenon corresponds to Litten's sign.

II. *Cutaneous Hyperalgesia.*—In an article published by Dr. Elsberg and the author on the "Diagnostic Value of Cutaneous Hyperalgesia (Head's Zones) in Abdominal Disease,"* the following statements were made concerning kidney and ureter zones: "The kidney zone is widest at the posterior median line, where it begins, and gradually narrows anteriorly. Its greatest breadth is at the spinal column, where it extends from the 10th to 12th dorsal spinous processes down to the lowest lumbar spine. It narrows to make a triangular area, with a rounded apex, situated a little to that side of the anterior median line on which the zone lies. We have never seen the kidney zone quite reach the anterior median line. Each zone is strictly limited to its half of the body. There is no difference in contour between the right and left kidney zones. The kidney zones are complicated by the additional ureteral zones that are present in certain cases. The ureteral zone springs, so to speak, from the lower margin of the kidney zone at the anterior axillary line. In an average adult it is about three inches wide at this beginning. It narrows in its downward course and passing obliquely downward and forward, it terminates on its side of the penis and scrotum in the male; the labia in the female. After the first narrowing it widens again well below the umbilical level. In the male, after this swell, it can be ascertained that the zone spreads fanshape to the anterior median line over the pubic area and its half of the scrotal and penile skin. There are anterior and posterior kidney maximal areas. The ureteral zone seems to be made up of a series of maxima. The kidney and ureteral zone is most often present, as in the other intraabdominal affections, in the presence of pain and tenderness. We have examined fourteen patients with renal calculus and have found a more or less marked zone six times. In most of the cases in which the symptoms were slight no hyperalgesia could be demonstrated. Two of four cases of pyelitis had zones, as had one patient with an acute pyelonephritis; one of infected hydronephrosis due to calculi, one of septic infarct in acute endocarditis, one of pyonephrosis. The more acute the renal affection the more apt is there to be a cutaneous hyperalgesia. Thus we have not found a zone in the large majority of patients with tumors of the kidney, with the exception of one case, in which the operation showed that there was a large fresh

*John Matthews, *The Lancet*, September 26, 1908.

†From the Admitting Department of Mount Sinai Hospital.

‡By surgical disease of the kidney is meant all suppurative conditions within the kidney and its pelvis, calculus, tuberculosis, and new growths.

*Elsberg and Neuhof: *American Journal of the Medical Sciences*, November, 1908.

hemorrhage into the tumor. When a calculus passes into the ureter from the kidney the kidney zone is apt to disappear and a ureteral zone develop. We have observed this in several instances and have been able to follow the passage of the calculus along the ureter by means of the skin hyperalgesia. Of eight cases of stone in the ureter, there was a more or less well-marked zone in six. In a case of rupture of the kidney there developed a well-marked ureteral zone after a severe colic. The colic and zone disappearing after the passage of a blood clot. The diagnostic value of localized areas of skin hyperalgesia in kidney and ureteral affection is not as great as in other abdominal affections, but in some patients it has had practical usefulness."

My additional experience in the main bears out these observations. Cutaneous hyperalgesia, however, has provd to be at least of equal value in the diagnosis of acute renal affections as of other acute abdominal conditions. In some of the less acute diseases of the kidney, pyelitis or calculus pyonephrosis causing pain, for example, we have frequently found more or less marked cutaneous hyperalgesia in the corresponding lumbar region. Such areas of hyperalgesia may be of irregular shape and distribution and thus may not conform to the typical zone as described by Head. Indeed, there is such variation in the shape and size and intensity of these irregular areas that they can scarcely be referred to as zones. They have, however, aided us in localizing disease to the kidney in not a few obscure instances.

III. *Muscular Spasm and Rigidity.*—Although rigidity and spasm of the lumbar muscles may sometimes be observed on inspection, the muscular contraction is much more readily discoverable by light palpation. There may be spasm not only of the quadratus lumborum group, but also of the corresponding erector spinæ and of the lateral abdominal wall. In very acute cases the entire hypochondrium on the affected side may be rigid, but however slight, it is the spasm of the quadratus lumborum that is of special significance in the diagnosis of obscure renal disease. When this physical sign is found correlated with the patient's history, we have learned to consider it almost pathognomonic of surgical disease of the kidney.

IV. *Lumbar Tenderness.*—Attention has been directed by Brewer and others to the point of tenderness in the costovertebral angle in cases of so-called unilateral septic nephritis. We have had but small experience with this disease. In the few instances in which it could with fair probability be diagnosticated, tenderness was present over the entire lumbar region on the affected side. We wish, however, to call attention here to a small area of tenderness that we have found many times in milder or subacute surgical diseases of the kidney, for example, in cases of pyelitis, renal tuberculosis, or tumor of the kidney associated with pain. This area of tenderness overlies the lowest two or three ribs at the margin of the erector spinæ or partly overlaps that group of muscle. It varies in size from the diameter of a dime to that of a silver dollar. Deep palpation may be required to elicit the physical sign. It is best accomplished by pressure by the tip of the crooked thumb. This tender area overlying the lowest ribs has often been found when tenderness in the costovertebral angle has been absent. It is apparently dependent upon the anatomical position of the kidneys, situated, as they are, in largest part in front of the lowest ribs. The physical sign has proven of considerable diagnostic value, especially as one of the signs that first calls attention to the kidney as the seat of disease in mild and obscure cases.

V. *Movements of the Trunk.*—It is, of course, only in ambulant cases not suffering much pain that one will attempt to employ movements of the trunk as an aid in the effort to associate vague symptoms complained of by individuals with disease of the kidney. The method is as follows: The patient stands with hands on his hips, is asked to hyperflex and hyperextend his spine and to bend his spine to the right and to the left. The hips may be supported by the observer, in order to permit of extreme trunk movements. In several otherwise obscure instances of surgical affections of the kidney this method has aided us in the correct localization of the disease.

VI. *Percussion of the Kidney Regions.*—Scant mention is made of this subject in text-books and monographs devoted to disease of the kidney and to the physical diagnosis. When at all mentioned renal percussion is generally dismissed with the statement that it is of no diagnostic value. Nevertheless, in our experience, percussion of the kidney regions has sometimes yielded very definite results. As far as can be ascertained from the literature, the only contribution to the subject of renal percussion in which a positive opinion as to its value is expressed, is a recent article by Lerch.* This observer employs "plexor-pleximeter" percussion (percussion hammer and an ivory plate) and uses a drop stroke and not the generally employed tapping method. He finds "that these organs (kidneys) can be mapped out with accuracy and ease, showing changes in size of a small fraction of one centimeter." According to this observer even the pelvis of the kidney can be outlined by percussion and "it is immaterial whether the colon is filled with fecal material or distended with gas." We have devoted considerable attention to the subject of renal percussion, but our results have not been at all comparable to those of Lerch. It is, however, but fair to state that we have only employed the ordinary percussion methods. In our earlier experiences we often found it difficult or even impossible to note if in any given case we were actually dealing with an area of dullness dependent upon the kidney. At that time many observations were made that were proven incorrect by further examination or by subsequent operation. It was found, however, that areas of renal dullness could be fairly well outlined in the lumbar regions if the colon was inflated. Since we have employed inflation of the colon as an aid to renal percussion, marked prolapse of the kidney or great enlargement of the organ (by a tumor, for example) have been correctly diagnosed in a number of instances. In obese individuals the method has usually proven of no value. It is in but one connection, however, that we believe percussion of the kidney to be of distinctly practical value, and that is in determining the presence or absence of the organ on one or the other side. Especially when combined with colonic inflation percussion of a kidney region will give a clear tympanitic note if the organ is absent on that side. We have seen this strikingly illustrated in three cases, one of which is the following: A thin, unmarried female, aged 20 years, applied

*Lerch, Otto: "On percussion and percussion of the kidneys," MEDICAL RECORD, February 4, 1911.

for admission to Mount Sinai Hospital, complaining of pain in the right iliac region where she had felt a tumor. She was referred to the hospital with the diagnosis of solid ovarian tumor. Upon physical examination, in the Admitting Department, the lower pole of the right kidney could just be felt in its normal position. In the right lower abdomen was an orange-sized mass that appeared to rise from the pelvis. From its contour suspicion was aroused that the tumor was an ectopic kidney. Percussion of the kidney regions demonstrated pure tympany on the left side, dullness on the right. The subsequent course of the history in the hospital proved that the diagnosis of left ectopic kidney was correct. Only by further experience with instances of completely displaced or absent kidney can an estimation of the practical value of percussion in the diagnosis of these conditions be made.

It has not been our object to decry the value of the more refined methods of renal examination: cystoscopy, ureteral catheterization, examination of the segregated urines, pyelography, etc., but to call attention to some methods that we believe should first be employed in cases of suspected surgical diseases of the kidney. No great originality is claimed for the methods of eliciting physical signs above described. Yet they are not in general use and when taken together they have aided greatly in pointing to the kidney as the seat of surgical disease in many otherwise indefinite cases. If an attempt be made to determine their value in obscure instances in which surgical renal disease is suspected, the aim of this paper will have been fulfilled.

1275 Madison Avenue.

A CASE OF ABORTIVE POLIOMYELITIS.

By RICHARD STEIN, M.D.,

NEW YORK,

VISITING PHYSICIAN TO THE GERMAN HOSPITAL.

Although the virus of acute anterior poliomyelitis has not as yet been demonstrated nor the mode or modes of transmission of this disease definitely traced,[1] considerable advance in the nosology of this disease has lately been made: infantile paralysis is an infectious as well as contagious disease; its early diagnosis and careful isolation will go far toward preventing the spread of the epidemic. Of especial interest are those cases of poliomyelitis of the abortive type, the nature of which is very difficult to recognize; in fact their relation to typical cases of poliomyelitis during the existence of an epidemic is often the only evidence we possess that they belong to the epidemic. Completely isolated cases of the abortive type will, as a rule, pass unrecognized. A communication of the American Orthopedic Association and American Pediatric Society states in its circular to the health authorities[2]: "Of particular significance are the so-called abortive cases . . . . (they) are undoubtedly a source of infection, and their record and study is of much importance. In a community where cases of infantile paralysis occur cases of illness with sudden onset of fever and meningeal symptoms should be closely watched and regarded as possibly infectious." Such a case was observed by me in my summer service at the German Hospital, New York:

J. W., six years old, born in the United States and residing on the upper east side of New York City, entered the hospital September 4, 1910, and was discharged cured September 21, 1910. Diagnosis: Acute dysentery, meningism. Family history: Father alive and well, mother died of consumption. Personal history: Born at term, breast-fed; measles last February. For the last few weeks he has been restless at night. On September 3 at noon he was seized with a chill, then complained of headache which gradually became very severe. He also gave evidence of drowsiness and gradually became unconscious. At the same time vomiting and diarrhea set in. Examination: Medium sized, pretty well nourished boy; he is in a state of coma, but responds if aroused. No general enlargement of glands. Rigidity of the neck and tenderness of spine. Examination of eyes, ears, and nose, negative. Pupils small, but there is tardy reaction to light. Pulse regular, not retarded, never accelerated. Examination of abdomen, negative. Spleen not enlarged. Slight Kernig sign of both lower extremities and Babinski reflex. Other reflexes normal. The highest temperature recorded was 103°. Further course of the disease: The case ran the course of an acute dysentery with hourly evacuations of a mucoid-blood, and, later, purulent nature. Microscopic examination showed an absence of amebæ. The number of stools gradually decreased. The urine never showed more than a trace of albumin. The complicating symptoms referable to the nervous system became very marked: opisthotonus, delirium, sleeplessness, and periods of extreme restlessness. Meningism, as a complication of acute dysentery, was noted as a rare occurrence. Lumbar puncture was made the day after admission; a clear fluid was obtained, which escaped under moderate pressure. The number of stools gradually diminished and the temperature and pulse became normal in the course of a week. The symptoms of meningism—stiffness of neck, Kernig's sign, etc.—subsided; the reflexes were never absent at any time. The patient was discharged cured after two weeks' illness. At no time was there any sign of paretic or paralytic condition of the extremities.

Although meningism occurs in many infectious diseases, especially in children, its occurrence in the course of acute dysentery was considered very remarkable, and hitherto not noted. On reading some of the literature on poliomyelitis, and hearing some reports of the gastroenteric type of this disease which occurred during the summer of 1910 on the Jersey coast, it was thought possible that this case of dysentery, described above, may have been a case of abortive poliomyelitis, on account of its cerebrospinal complications. This suspicion was strengthened after hearing the lecture by Dr. Flexner on poliomyelitis, October 24, 1910. After communicating with Dr. Flexner, Dr. Blumgarten, my house physician, and myself visited the residence of the patient. As far as could be ascertained, there were no other cases in the tenement at the time. The patient was perfectly well. Two ounces of blood were taken from the median cephalic veins and subjected to the neutralization tests by Dr. Flexner.[3] These tests showed a positive result. As there was nothing in the patient's history pointing to an attack of poliomyelitis previous to the illness for which he was treated by us in the hospital, it can be inferred that we were dealing with a case of abortive poliomyelitis.

ALBUMINURIA OF ADOLESCENTS IN RELATION TO LIFE INSURANCE.

THE question of the nature and prognostic significance of the various forms of albuminuria, usually of intermittent type, occurring in adolescents and young adults, is one involved in much obscurity. Formerly albuminuria was albuminuria and its occurrence was regarded as a sign of impairment of kidney function prejudicial to the health or life of the subject. Today there is a tendency to belittle its importance, although the insurance companies are not yet ready to ignore it as a factor in determining the acceptance or rejection of risks. The question was very thoroughly discussed and possibly brought nearer a definite solution, at two recent meetings (April 25 and May 2) of the Medical Section of the Royal Society of Medicine of London. The discussion was opened by J. F. Goodhart with a paper entitled "The After-History of Cases of Albuminuria Occurring in Adolescence." The author based his remarks upon a review of his case-records for the last twenty-seven years embracing 237 cases, though several of these were excluded for various reasons. He preferred the term "cyclic" as applied to these cases, rather than "postural," for he was not inclined to regard posture as influencing the excretion of albumin. He was of the opinion that the fault is largely a digestive one, due to the fact that defectively prepared products or even acceptable materials reach the kidney in too great an excess for the secreting cells to deal with. He was able to obtain a definite after-history in only 38 of his cases. In these the last observation was separated from the first by intervals of from thirty years down to two, 28 having more than a five-years' after-history. In all of these cases the report stated that the albuminuria had disappeared, and the author believes that in many if not in most of the other cases the outcome was equally favorable, for the patients were in the hands of competent observers and had they turned out badly he would no doubt have heard of it, at least in a certain proportion of the cases. His conclusion was that the albuminuria of the adolescent has no sinister effect upon health or upon the duration of life, and that with due circumspection such cases ought not to be excluded from the advantages of life insurance.

The majority of those who took part in the discussion differed from the reader of the paper in his explanation of the condition of adolescent albuminuria, regarding it as, in most cases, purely postural or orthostatic. They were, however, in accord with him in looking upon it as a condition of little gravity and of no serious prognostic significance, for it almost invariably disappeared with the termination of school life and the abandonment of strenuous athletic contests, and sometimes after the marriage of the subject. Saundby stated that he had been able to follow up 24 of his cases, extending over a period of from five to thirty years. Of these patients only one had died, the cause being acute myelitis, but the albuminuria had disappeared several years before the onset of that disease. All the others were living and in good health. His opinion was that, if each case of albuminuria was carefully studied and set down as albuminuria of adolescence only when all means of investigating it had been exhausted, a good prognosis could be safely given. Clement Dukes expressed the conviction that adolescent albuminuria does not lead to organic disease, but is of a temporary character during growth. He repeated what he had written in a paper read at the meeting of the British Medical Association in 1905: "I enter a decided protest against these albuminurics having their education interfered with, their games prohibited, their food supply curtailed, with consequent insufficient nutriment for growth, and their life insurance deferred." Mitchell Bruce had gone through a certain number of his case-books and had found 13 cases of typical albuminuria of adolescence. Two of these cases he could not trace, one patient had died of Bright's disease, the remaining ten were now freed from albuminuria. Nestor Tirard was not inclined to regard the condition as lightly as did most of the other speakers, and he thought great caution was necessary in accepting cases of so-called functional albuminuria for life insurance, notwithstanding that he admitted having seen a number of instances in which albumin disappeared from the urine after marriage. Many interesting points were brought out in the discussion regarding the varieties of adolescent albuminuria, its nature and mode of causation, and the associated mental and physical conditions, but space forbids more than this reference to them here.

The general consensus of opinion of the many experienced clinicians of London and the Provinces who took part in this discussion, as to the benign character of the albuminuria of adolescence, can but be consoling to the individual subject, if he takes any serious thought of his condition one way or another, and especially to his physician, but how far it will go toward solving the problem as it is presented to the medical examiner or director is another matter. The family physician, when meeting with a case of albuminuria in one of his young patients, can study the case at his leisure, examining the urine passed at different times of the day, and over long periods, observe the relation of albumin excretion to the varying conditions of exercise and rest, study, mental anxiety, etc., and note its association with the ups and downs in the general physical state. The insurance ex-

aminer, however, sees the applicant but once, and if he finds the urine loaded with albumin his report is likely to be unfavorable. If the general health is otherwise good, a second urinary examination may be made, but unless the morning urine is examined the report will probably be the same. A long-distance diagnosis by the home office of adolescent albuminuria would, in such a case, be a risky procedure, and so the application would in all probability be turned down or deferred. In the meantime the applicant might go elsewhere, and then, if the urine happended to be examined at an albumin-free period, he would be accepted, and another company would secure a good risk. It is evident that the problem of albuminuria of adolescence is one of great practical interest to insurance medicine, for the diagnosis of the condition is not easy, even to the family physician and still less to the medical examiner or director.

THE SERUM TREATMENT OF INFLUENZAL MENINGITIS.

Within recent years many cases of influenzal meningitis have been reported as the result of the increasing practice of bacteriological examination of the cerebrospinal fluid. The recovery of only six out of fifty-eight cases of influenzal meningitis indicates the high mortality of this disease. In view of these facts considerable importance must be accorded to the recent investigations which have resulted in the preparation of an immune serum with a specific curative action in the case of experimental influenzal meningitis in the monkey.

These investigations have been performed by Martha Wollstein, who describes her results in the *Journal of Experimental Medicine*, July 1, 1911. Her preliminary experiments had shown that it is possible, with the aid of virulent cultures of the influenza bacillus whose pathogenicity has been maintained by frequent passage through the rabbit and occasional passage through the monkey, to produce influenzal meningitis in the latter animal by introducing suspensions of the cultures into the subarachnoid space in the lumbar region. This injection is followed by a meningitis which is identical with the clinical form in human beings, and which terminates fatally in from thirty-six hours to four days. Dr. Wollstein's next step was to produce by means of repeated injections, over a period of eighteen months, of living virulent cultures of the influenza bacillus into the goat, an immune serum possessing moderate agglutinating and high opsonic power, which is capable, when injected into the subdural space, of arresting the progress of experimental influenzal meningitis in the monkey and of bringing about recovery. As the result of the serum injections the influenza bacilli are more freely taken up by the leucocytes, their number is reduced, their capacity of growth diminished, and their invasion of the blood arrested. At the same time the local inflammatory process subsides, and rapid recovery of health ensues.

The use of this serum has not yet been resorted to in the case of human beings, yet there can be little doubt that it will prove as efficacious in influenzal meningitis as the antimeningococcus serum in the epidemic form of the disease. Dr. Wollstein emphasizes the importance of applying the serum early and by repeated injections, by means of lumbar puncture, after the prompt bacteriological diagnosis has been made by the immediate microscopical examination of the cerebrospinal fluid, without the employment of cultural methods. This diagnosis may be confirmed later by cultural tests. It is to be hoped that a supply of this serum will soon be available for use in human beings.

METASTASES TO THE BRAIN.

The laws which govern the formation of metastases, especially those of proximal location, are by no means fully understood. That such laws exist and apply equally to neoplasms and pyemic abscesses is sufficiently evident; and it is of great clinical interest that the proximal metastases are often in evidence before the primary focus, and that in rare cases no primary focus can be found.

At a recent meeting of the Freie Vereinigung der Chirurgen Berlins (*Deutsche medizinische Wochenschrift*, May 25) Groth read a paper on cerebral metastases which provoked an extensive discussion. He stated that in a preponderance of cases both metastatic abscesses and metastatic neoplasms proceeded from primary foci in the pulmonary organs. It appears at first sight paradoxical that in endocarditis metastases to the brain are relatively rare. In cancer of the lung the metastases are usually limited to the brain. A case was cited in which, six months after operation for a metastatic growth in the brain, the primary focus in the lung first made itself evident clinically. The fact that metastatic cerebral abscesses may be multiple need not deter the surgeon from operating.

Neumann called attention to the fact that cerebral abscesses may represent true metastases even though the primary focus be seated in one of the nasal sinuses. One cannot straightway conclude that all such lesions develop as a result of phlebitis. Borchardt called attention to the association of a metastatic tumor focus with suppuration. In such a case the clinical diagnosis may be metastatic abscess. In an example cited the primary focus was a carcinoma of the lesser curvature of the stomach. Mühsam showed a preparation of a metastatic brain tumor following a deciduoma malignum which had been successfully removed. Most of the viscera participated in the metastases. In such cases the brain deposits are not proximal in character, but part of a general process. Zeller, quoting from Prof. Sonnenburg's material, stated that it was extremely rare for the surgeon to operate successfully in metastatic abscess. Much of the discussion dealt with localization symptoms, from which it appears that our knowledge of centers of associated movements is notably asymmetrical. Much is known of some centers and little of others.

Ochronosis as a Familial Disease.

The tendency of rare and newly described diseases to appear in blood relatives, and of some of them to occur only in children of a single family, is well

known, and is exemplified in the fact that the very rare affection known as ochronosis has been reported as affecting three sisters. This endogenous ochronosis must not be confounded with an exogenous type due to chronic carbolic acid poisoning. Ochronosis was first known as a pathological affection, and as such has been mentioned in textbooks on pathology since Virchow's time as a species of pigmentation. At a later period a clinical syndrome of the affection was isolated. Not over twenty-six such clinical endogenous cases are upon record for analysis. Five others are not sufficiently described. Of the twenty-six cases, sixteen presented alcaptonuria. Other clinical phenomena are a discoloration and hardening of the external ear and a diffuse macular gray discoloration of the sclerotic coat of the eye. Less common are a blueness over the nasal cartilages and a comedo-like appearance of the face, a brown discoloration of the palms, black ear wax, and greenish axillary perspiration. At autopsy pigment changes in the bones and cartilages are found, in frequent association with cardiovascular changes. Kolaczek, from whom we have cited the above data, read his paper before the Tübingen Society of Naturalists and Physicians last February (*Münchener medizinische Wochenschrift*, April 25) and reported three cases of the affection in sisters aged between thirty and forty-six years. He controlled a total family membership of thirty-five living individuals of three generations, all of whom were tested for ochronotic changes and alcaptonuria. Aside from the three sisters, who presented both ochronosis and alcaptonuria, all these individuals were normal. The parents of the sisters were first cousins. Simple alcaptonuria, occurring without ochronosis, has already been placed on record both as a family affection and as one connected with consanguineous marriages. It may therefore be a sort of parent affection to ochronosis.

Pyretogenic Action of Sodium Chloride.

A generation ago works on materia medica did not recognize such a class of drugs as pyretogenics. It was of course understood that in severe cases of poisoning the heat center might be affected; but of a class of remedies acting especially on this center, or otherwise able to cause pyrexia, there was no general recognition. The tuberculin febrile reaction was perhaps the first phenomenon to call attention to such a possibility, but with biological reactions so-called we have nothing to say in this connection. It is quite apparent that bacterial toxins should be able to produce fever, whether generated without or within the organism. The power of nuclein-containing substances to produce fever when injected subcutaneously, and of adrenalin to induce the same phenomenon in animals need not be discussed here. It must, however, be remarked that our knowledge of the pyretogenic power of drugs is derived very largely from animal experiments. At a meeting of the Heidelberg Union of Natural History and Medicine (*Deutche medizinische Wochenschrift*, April 27) Freund discussed salt fever. Sodium chloride can induce fever in rabbits, which fever is antagonized by calcium and other salts. The salt phenomenon belongs under the head of aseptic fever, and occurs in mankind in certain cases with special predisposition. The resemblance to adrenalin fever is so marked that the author entertains the supposition of the power of sodium chloride to mobilize the adrenalin in its native glands. Both fevers are accompanied by glycosuria, and both are antagonized by calcium salts. But salt fever is offset specifically by the action of cholin and pilocarpine, which may suggest that sodium chloride acts pyrogenetically through the vasomotor system.

Exhaustion of the Chromaffin System.

The chromaffin system comprises the suprarenal bodies, carotid glands, and paraganglia, all of which structures produce adrenalin. It receives its name from the fact that certain cells in these organs color immediately with solutions of chromium salts. The product of the chromaffin cells or adrenalin exerts a tonic influence throughout the organism. This is shown by the fact that in Addison's disease, sepsis, pneumonia, and diphtheria, where there are much prostration and threatened collapse the natural supply of adrenalin is largely exhausted, and this deficit may be antagonized by the prophylactic use of artificial adrenalin. At a recent meeting of the Verein für wissenschaftliche Heilkunde of Königsburg (*Berliner klinische Wochenschrift*, June 12) Carl after summing up our knowledge of the chromaffin system mentioned an autopsy upon a bicyclist who died in collapse after extreme exertion. The cells in the adrenal bodies refused to stain with chromium. Again, when frogs were exhausted from strychnine convulsions the same refusal to stain was apparent. In discussion two of the members pointed out a possible source of fallacy as far as the strychnine experiment is concerned. The alkaloid may possibly affect the chromaffin cells directly and without the mediation of exhausting convulsions. It is possible to strychninize a frog without the production of reflex convulsions. If strychnine is an antidote to adrenalin, as has been claimed, it might exert a direct action on the chromaffin cells.

News of the Week.

Cholera in New York.—Because of the development of a case of cholera after the patient had been detained in Quarantine for five days, it has been decided that it will be necessary to lengthen the period of detention to ten days. The patient in this case arrived in New York on the Italian steamer *Duca degli Abruzzi*, and after the usual detention was allowed to proceed to Brooklyn. Four days later she was taken ill with symptoms of cholera, and was removed to the Quarantine hospital, where she died. On several other steamships arriving from Mediterranean ports suspicious cases have been found, and the United States Public Health and Marine-Hospital Service is cooperating with Dr. Doty in safeguarding the port.

Deaths in New York.—To the excessive heat in New York during the week ending July 8, 197 deaths were ascribed, the total number of deaths in the city being 1,746, or 74 more than during the corresponding week of 1910. The deaths from heat were almost entirely among persons over forty-five years of age, the mortality among infants seeming to be but little affected by the unusual weather conditions. During the week there were 343 deaths among children under one year of age, whereas a year ago there were 438, and the deaths due to diarrheal diseases decreased 50 per cent. During the first six months of 1911 there were 7,337 deaths from all causes among infants under one year of

age in New York, a decrease of 10 deaths as compared with the same period of 1910, though the death rate fell from 121 per thousand to 117.

Plague in Manchuria.—Dispatches from Irkutsk announce that a fresh outbreak of pulmonary plague has appeared in Manchuria.

School of Tropical Medicine.—Beginning with the next session, the Medical Department of Tulane University, New Orleans, will inaugurate laboratory and systematic courses in tropical medicine, hygiene, and preventive medicine, which it is hoped will in time be expanded into a full School of Tropical Medicine and Hygiene. The initial course will open on September 29, 1911.

The Rockefeller Institute.—Announcement is made that the Rockefeller Institute for Medical Research, New York, will devote its resources very largely during the present season to the study of infantile paralysis or anterior poliomyelitis, and to the treatment of acute cases of this disease in its hospital. Physicians and health officers desiring to cooperate in this investigation may do so by sending information concerning the occurrence and prevalence of this disease, or by referring acute cases to the hospital of the Rockefeller Institute. Dr. Flexner renews his request of last year, that whenever possible a portion of the spinal cord and of the nasopharyngeal mucosa derived from fatal cases of the disease be sent to him. Specimens should be preserved in glycerin and sent by mail to Simon Flexner, M.D., Sixty-sixth street and Avenue A, New York, N. Y.

Experiments on Pike's Peak.—Dr. J. A. Haldane and Dr. Gordon Douglas of Oxford University, England, who intend to conduct a series of experiments during the summer on the summit of Pike's Peak to determine the effect of high altitudes on the human blood, arrived in Colorado Springs on July 7. They will be assisted by Dr. Yandell Henderson of Yale University and Dr. E. C. Schneider of Colorado College.

Dr. Herbert Fox has been elected director of the William Pepper Laboratory of Clinical Medicine in the University of Pennsylvania. For the past five years Dr. Fox has been the first Chief of Laboratories of the Pennsylvania State Department of Health.

Dr. Robert Lamb, medical superintendent of the Matteawan State Hospital, tendered his resignation to the Superintendent of State Prisons on July 7, to take effect immediately. Dr. Lamb has been in the State service since 1891, and was formerly superintendent of the Dannemora State Hospital.

A Sane Fourth.—The New York State Department of Health announced on July 5 that for the first time in the history of the department no cases of tetanus had been reported following the celebration of the Fourth of July. Eighteen cases were reported in 1910.

University of Pennsylvania.—The following changes in the Medical Department of the University of Pennsylvania have been announced: Dr. T. Turner Thomas has been promoted to be associate professor of applied anatomy, and Dr. George W. Norris to be assistant professor of medicine in succession to the late Dr. A. O. J. Kelly. Dr. J. Rex Hobensack, Dr. P. G. Skillern, and Dr. Nate Ginsburg have been made assistant demonstrators of anatomy, Dr. Norman L. Knipe, assistant instructor in obstetrics, and Dr. Oscar H. Plant, demonstrator in pharmacology. Dr. J. H. Austin, demonstrator in pathology, is to become associate in research medicine; Dr. A. B. Eisenbrey, associate in research medicine, is to become instructor in gynecology; Dr. J. G. Hickey, absent on leave, will resume duty as assistant in physiology; Dr. A. H. Hopkins will become assistant instructor in gynecology; Dr. Ralph S. Lavenson, absent on leave, will resume duty as instructor in medicine; Dr. W. H. MacKinney will become associate instructor in genitourinary diseases; Dr. W. C. Rose will become instructor in physiological chemistry, and Dr. A. H. Woods will become lecturer on electrotherapeutics in succession to Dr. A. R. Allen.

Summer Courses in Medicine.—The College of Physicians and Surgeons, Columbia University, New York, opened its summer session on July 5, courses being offered in bacteriology under Prof. Wadsworth, in clinical pathology under Prof. Wood and Prof. Vogel; in physiological chemistry under Prof. Gies and Mr. Rosenbloom; in nutrition under Dr. Foster, and in physical and medical diagnosis under Dr. James A. Miller, the last course being given at Bellevue Hospital.

Slaughter Houses in New York.—The Bureau of Municipal Research of New York has been investigating the conditions in the East Side slaughter houses in the city, and has reached the conclusion that the law is being violated, and that the "Department of Health has not only not stopped but has permitted the violations in one instance," in permitting the rendering of shop fat. The report says that blood is allowed to flow into the East River from the slaughter houses, and that tuberculous cattle have been slaughtered, and the meat sold in the Brooklyn slaughter houses, although this practice has been stopped for the time being. In conclusion the report says that it is possible to conduct every legitimate part of the slaughter house business without committing a nuisance, and that the "fundamental deficiency is with the attitude and manner of supervision of the Department of Health."

Crusade Against Smokers.—The Non-Smokers' Protective League of America has asked for incorporation papers in New York State. The stated purpose of the organization is the enforcement of all laws and regulations against smoking in public and semi-public places, to attain which end it promises to cooperate with boards of health and police and other peace officers. Lecture bureaus will be conducted, and the organization will publish books and magazines, and establish auxiliaries in all parts of the country.

Gifts to Charities.—St. John's Guild and the Adirondack Cottage Sanatorium receive bequests of $10,000 each under the will of the late Mrs. May Cossitt Dodge, and also share in the residuary estate. The Lincoln Hospital of New York also receives a bequest of $25,000.

The Roosevelt Hospital, New York, receives a bequest of $500 under the will of the late Josephine Clay Strong of Setauket, Long Island.

Mt. Sinai Hospital receives $1,000, and the New York Medical School for Women, St. John's Guild, and the New York Skin and Cancer Hospital $500 each by the will of the late Mrs. Esther Hermann of New York.

The Seventh International Congress on Tuberculosis will be held in Rome, Italy, on September 24 to 30, 1911, under the presidency of Prof. Guido Baccelli. The congress will be divided

into three sections: I, Combined hygienic work; II, pathology and therapeutics, with two sub-sections, (1) medical, and (2) surgical; III, etiology and epidemiology.

Montreal (Quebec) Medico-Chirurgical Society.—At the last regular meeting held on June 24 the following officers were elected for the ensuing year: *President*, Dr. J. M. Elder; *Vice-President*, Dr. D. J. Evans; *Treasurer*, Dr. R. P. Campbell; *Secretary*, Dr. S. Handford McKee; *Trustee*, Dr. C. J. Martin.

The Georgia Association of Physicians and Surgeons was organized recently at Atlanta with Dr. George Brown of Atlanta as *President*, and Dr. C. M. Curtis of College Park as *Secretary* and *Treasurer*.

Obituary Notes.—Dr. Edmund L. Cocks of New York, a graduate of the Bellevue Hospital Medical College in 1885, visiting dermatologist to Randall's Island and the Harlem Hospital, and clinical assistant at the Skin and Cancer Hospital, a member of the New York State and County Medical Societies, and of the New York Academy of Medicine, and professor of dermatology in Fordham University, died at his summer home in Far Rockaway, on June 5, after a short illness, aged 55 years.

Dr. Abner C. Matthews of Earlville, N. Y., a graduate of the University of Vermont College of Medicine, Burlington, in 1894, died suddenly at his home on June 27.

Dr. Walter S. King of Cedar Rapids, Ia., a graduate of the Rush Medical College, Chicago, in 1894, attending physician to St. Luke's Hospital, coroner of Linn County, and a member of the American Medical Association, the Iowa State and Linn County Medical Societies, and the Iowa Union Medical Society, died in St. Luke's Hospital, Cedar Rapids, on June 16, from injuries received in an automobile accident a few days before, aged 59 years.

Dr. Thomas S. Mitchell of Pensacola, Fla., a graduate of the Atlanta Medical College, Georgia, in 1866, and a member of the Florida State and Escambia County Medical Societies, died suddenly of apoplexy at his home on June 20, age 75 years.

Rear Admiral Edward Shippen, United States Navy, retired, a graduate of Princeton University and of the Medical Department of the University of Pennsylvania in 1848, a surgeon in the Navy since 1849, at one time Chief Medical Inspector of the Naval Academy at Annapolis, and from 1872 to 1879 in charge of the Philadelphia Naval Hospital, and a member of the College of Physicians of Philadelphia, died at his home in Chestnut Hill, Philadelphia, on June 16, aged 85 years.

Dr. Thomas Hunter of Philadelphia, a graduate of the Medical Department of the University of Pennsylvania in 1872, died at his home on June 20, aged 61 years.

Dr. Robert Carter, formerly a surgeon in the United States Navy, died at his home in Philadelphia on June 22, aged 84 years.

Dr. J. W. Coble of Tamaqua, Pa., a graduate of the Medical Department of the University of Pennsylvania in 1867, and a member of the Pennsylvania State and Schuylkill County Medical Societies, died at his home on June 22, aged 69 years.

Dr. Julia Hibben Flagg of Vancouver, Wash., a graduate of the Medical College of Indiana in 1890, a member of the Clarke County and Washington State Medical Societies, and of the Portland, Ore., City and County Medical Societies, and an ex-member of the Indianapolis Medical Society, died at her home on June 2, of cerebral laceration as the result of an accident. Dr. Flagg had seen much service in the Philippines with her husband, Major Flagg of the United States Army Medical Corps, and was at one time connected with the Division Hospital at Dagupan.

Dr. James Carmichael Hutchison of Troy, N. Y., a graduate of the College of Physicians and Surgeons in 1866, a member of the New York State and County Medical Societies, and for twenty-three years attending physician to the Troy Hospital, died at his daughter's home in Rockford, Ill., on June 11.

Dr. Mason Thomson of New York, a graduate of the Bellevue Hospital Medical College in 1876, died at his home on July 6.

Dr. Thomas H. Wilde of Baldwin, L. I., N. Y., a graduate of the Long Island College Hospital in 1906, died at his home, of pneumonia, on July 4.

Dr. Samuel Zeigler of Greenville, Pa., a graduate of the University of Pennsylvania in 1899, and a member of the Pennsylvania State and Mercer County Medical Societies, was killed in an automobile accident at Dunkirk, N. Y., on July 2.

Dr. Henry P. Calhoun of Cottonwood, Ala., a graduate of the Atlanta Medical College in 1895, and a member of the Alabama State and Houston County Medical Societies, died at his home of paralysis on June 26.

Correspondence.

ELABORATION OF HOSPITAL ORGANIZATION.

To the Editor of the Medical Record:

Sir:—I have just read in your issue of June 24 Dr. Blake's and Dr. Thompson's articles on the organization of hospital staffs, as well as the discussion of their papers at the meeting of the Practitioners' Society.

It may be that in some directions and for good reasons the plans outlined with much talent and clearness and indeed now in practice at Bellevue Hospital, may be found desirable to give accurate, systematic instruction of advanced kind to those who are able to follow it closely and sufficiently. On the other hand, will it be found especially useful later to many who are obliged to practise their profession outside university or other hospital wards and for the benefit of private patients? I do not believe it will unless it be understood and insisted upon that many things which are daily routine in hospitals are almost impossible to follow elsewhere, unless means are large and assent is given to their practical value. If this be true, whatever additions must occur in further scientific medical pursuit will only add to the difficulty.

Again, science is one thing; art another. Science of medicine teaches in heart disease, for example, that the time, intensity, rhythm, and variation of every heart murmur are significant. Art of medicine declares these findings, so far as treatment of and consequences to patients are concerned, have frequently little importance. Science would make it essential to analyze stomach contents after a test meal and follow this procedure frequently with other physical interference, such as the exhibition of large doses of bismuth, the taking of an *x*-ray picture, and inflation of the bowels, whereas art

recognizes that despite their revelations symptoms may be and are relieved until diagnosis is evident and without previous doings of advanced knowledge. In any event, and not to multiply examples, it should be widely disseminated that the best practitioner is not necessarily the man who is expert in newest methods—which experimentation, pure and simple is constantly producing—but is the man who has observed long and well and who holds his judgment in reserve while utilizing everything valuable that is acquired for the benefit of his patients. Such a one is the medical Judge of the Court of Appeals, so to speak, who decides what is best to do for the patient when all the facts are known. Among these facts—and here science is often sadly amiss and art triumphant—the personal equation of the patient stands out as a subject for closest study and interpretation. I claim, and rightly, that sympathy in our daily walks of practice, hospital or other, should essentially control, and this need is largely ignored when we follow ceaselessly science in medicine with faint consideration for the art which always notes the variable, trustful, emotional human aspect in every case of disease.

Beverley Robinson, M.D.

New York.

LONDON LETTER.

(From our Regular Correspondent.)

CORONATION HONORS—THE INSURANCE SCHEME, REPRESENTATIONS OF MEDICAL CORPORATIONS AND INDIVIDUALS—EFFECTS OF DRINKING HARD WATER—RESEARCH DEFENCE ASSOCIATIONS—THE BUTLIN DINNER—OBITUARY.

London, June 23, 1911.

Coronation week! The long anticipated event has arrived and is past. It has seemed to displace almost all other subjects of conversation but you will have had full descriptions by cable The one medical point of interest is that in the long list of honors conferred on the occasion the profession is not left out. Among twenty baronetcies the following well-known names are found: C. B. Ball, H. T. Butlin, J. F. Goodhart, William Osler, and W. T. Stoker. There are fifty-five knighthoods conferred and among them on A. A. Bowlby, A. Dempsey, F. W. Hewitt, and F. C. Wallis. Promotions from C.B. to H.C.B. are Ronald Ross and A. Whitelegge; to the K.C.M.G., J. Pringle, and J. R. Bradford. The C.M.G. is given to J. W. Barrett (Melbourne), T. Zammit (Malta), and D. Christie of the Chinese missionary body. The agent-general in London for Tasmania is a doctor, viz. Hon J. McCall, M.D., and he is knighted.

In the Military Division of the Bath, C. C. Godding, William May, J. G. MacNeece, G. W. Robinson, C. F. Willis, and T. Grainger become companions, and A. S. Reid, W. L. Gubbins are promoted to the upper rank. In the civil division, H. Todd, W. Bassett-Smith, P. B. Giles, H. R. James, and G. S. Elliston are made companions.

In the Royal Victorian Order, B. Dawson becomes knight, A. R. Bankart, R. N. M. Rees, and Mayo Robson are made companions, and William Fairbank becomes a member. In the territorial force J. R. Thomas, M.D., and Damar Harrison, F.R.C.S., are appointed as Honorary Physician and Surgeon to the King, respectively.

Sir James Reid, Bart., who has been physician to the late King Edward and to the late Queen Victoria, has been authorized to add to his armorial bearings a special honorable augmentation, in consideration of his services to those sovereigns. But these honors and even all the magnificent ceremonies of the coronation cannot diminish the intense interest and excitement produced in the profession by the state insurance scheme. Meetings of medical men all over the country, articles and letters in the press and other evidence of this is being forced on the attention of Parliament and the public. Mr. Lloyd George has replied to the representations of the General Medical Council in a letter to the president, Dr. Macalister. In this "considered reply" he makes some apparent concessions, such as that he has always intended to put doctors upon the advisory committee, adding that the bill provides that they should be on the local health committee. But other points he passes lightly over, partially agreeing or saying it is "not proposed," or he "will consider," or similar expressions. He refuses a wage limit and his remarks about the free choice of a doctor are insulting. Moreover, he seems determined to rush his bill, if possible, through its remaining stages as recklessly as he has so far pushed it, and that in spite of the general demand for delay which I told you was urged. The Royal College of Physicians has added its voice to the call for delay and has invited its licentiates to supply it with facts as to how the scheme will affect their practices to enable the college to deal with the question.

The Edinburgh College of Surgeons, which led the demand for delay, has sent a second letter to the Chancellor urging that it is increasingly evident that reconsideration is necessary and that "if this measure be rushed through Parliament with all its imperfections it will, we fear, produce a deadlock greatly to the disadvantage of the general public."

The Central Hospital Council for London has passed a resolution with regard to the work of the hospitals all over the country to "impress on the government the necessity of sufficient time being allowed for the consideration of the bill in all its aspects." Other bodies are putting forward their objections and individual members of the profession are expressing their views in the public papers or addressing their representatives in the House of Commons. Sir T. Barlow, as I mentioned, thinks that medical attendance had better have been left out of the scheme, a view which not a few hold. Payment for services rendered is a just plan and has always worked well, while contract practice has proved by long experience intolerable.

Sir Alfred Pearce Gould, who would make a splendid leader if all would rally to the support of his views, has pointed out that a mistake has been made from the first by objecting to details, when the principle of the bill should have been opposed. He would say to the government "we will have nothing whatever to do with contract practice or *per capita* payments." The profession, if united, could thus settle controversy and continue its beneficent work as heretofore.

The influence of calcareous water in health and disease has lately been much talked about. It was, therefore, an appropriate subject for the Balneologists who held an annual meeting at Folkestone which situated by the sea and on chalk has been reported by the public to cause gout, eczema, constipation, and numerous other maladies. Dr. Percy Lewis of the town opened a discussion in a paper

stating a number of antitheses, such as A. says hard water does harm in, etc., while B. says the contrary. Dr. Pernet followed and held that drinking calcareous water did not excite eczema though locally its effect was bad. At the seaside the climate was often responsible for aggravating the disease. Dr. Bagshawe said hardness was not always due to calcium; at Hastings there were no chalk rocks and the water was only hard at times from an irregular quantity of iron dealt with by magnetic filtration. Dr. Tyson pointed out that in inland towns calcareous water did not seem a factor of the diseases attributed to it by the sea and he thought they were due to climate. Dr. Clippendale from a study of the Chiltern Hills concluded that the process used for softening the water had diminished the tendency to calculus but increased that to gout. Dr. Lennox Wainwright said there were three factors to consider—the diathesis of the patient, the climate, and the water supply. Londoners who had led strenuous lives came to Folkstone and required individual care as to diet including water. Hard water was usually free from contamination. Softened and distilled waters were hardly possible in town supplies. Chalk could be got rid of but lead and disease might still be carried. Dr. Leonard Williams said the acids, uric and oxalic, were responsible for the formation of calculi—not the calcium base which could not be got rid of even if one wanted to. Dr. Bateman said Folkestone water contained from 2½ to 3 grains per pint, but when boiled only about ½ a grain—not enough to be deleterious. Dr. A. F. Street said if water from chalky soils had the ill effects some alleged the people and the practitioners around must be familiar with them. The evidence was against the allegations.

The Research Defence Association held its annual meeting on Monday at the Royal College of Physicians, when Lord Cromer presided. Mr. Sydney Holland moved the report and said the membership had increased to 4,600 and its importance grew every day. It was monstrous that their opponents should have opened shops exhibiting wilful distortion of truth. Dr. Sandwith seconded, Sir F. Treves and Mrs. Garrett Anderson supported. Lord Cromer said one set of opponents distorted facts and wilfully calumniated a noble profession. Another set adopted an impossible ethical standard and might be respected but nothing would influence their prejudices. A third category of critics admitted the necessity of experiment but urged that pain should be obviated as far as possible. Here they were on common ground. In reference to his being vice-president of the society for preventing cruelty to animals, he did not think it inconsistent with the presidency of this association as some extremist had declared. He would admit any reasonable safeguard that the Royal Commission would suggest. Dr. Sandwith bore testimony as an eye-witness to the reforms Lord Cromer had effected in Egypt as to the treatment of animals.

The dinner to Mr. Butlin on the 13th inst. was a remarkable success. I do not remember a compliment of this kind so universally approved. In reply to the toast of his health he touched on the absorbing subject of the Insurance Bill and disposed of the assertion of the Chancellor that the loss inflicted on some could be balanced by gain in increase of the number of poorer patients. He said many doctors living on practices of £200 a year would be ruined and it was no comfort to them that some others might be better off. The gain of A. was no consolation to the loser B. He would not support threatening language but he thought trade unionism as legitimate for the medical as for the legal profession. Everyone seems specially gratified that the name Henry Trentham Butlin, President of the Royal College of Surgeons, appears in the list of coronation honors. He now ranks as Baronet.

Sir Rubert Boyce, F.R.S., M.B., London, dean of the Liverpool Tropical School, and professor of pathology in the University, died on Saturday morning. His special researches on tropical diseases and his work in organizing the expeditions of the school will be familiar to you. He was founder of the school in conjunction with Major Ronald Ross and the late Sir Alfred Jones and in 1906 he was knighted as a slight recognition of his services in these matters. He had also been awarded the Cross of Leopold II and was on the Commission on Tuberculosis. He wrote a "Text-book of Morbid Histology," "Mosquito or Man," and "Health Progress in the West Indies." This year he published a work on "Yellow Fever and Its Prevention," intended as a manual for students and practitioners, in which he relates his experience and investigation in Honduras, New Orleans, Central America, the West African colonies, and other parts from 1905 to date. In this he goes very thoroughly into a number of questions concerning yellow fever, its epidemiology, entomology, and prevention. He held that the disease was not always recognized because many cases of bilious or remittent fevers were in reality mild forms of the more grave infection. He thought that African natives acquired immunity through such mild forms in early life, but might when adults furnish a supply of virus to the stegomyia, which abounds on the African coast, and speedily attacks new arrivals. There is general regret at his loss just as he had submitted his views to the consideration of the profession.

Dr. Moses Thomas, one of the senior practitioners in Glasgow, has died in his 82nd year. He took the License of the Faculty in 1857 and in 1862 the M.D. of St. Andrews. He was superintendent of the Royal Infirmary from 1867 to 1902, when he resigned. In 1874 he published an account of the results of amputations in the infirmary for 80 years preceding, covering the time of the introduction of Listerism and its effects.

Deputy Surgeon-General Arthur Grey Elkington, who died on the 31st ult., in his 79th year, served in the Crimean War, was wounded at the battle of Inkerman, and was present at Balaklava and at Sevastopol. He received medals and clasps and the Turkish Order of the Medjidie. He was in the Guards from 1853 to 1887, when he retired.

THE CANADIAN MEDICAL ASSOCIATION; FORTY-FOURTH ANNUAL MEETING.

(From Our Special Correspondent.)

MONTREAL, June 19, 1911.

THE address in surgery was given by Dr. A. Primrose, professor of clinical surgery in the University of Toronto. The speaker said, in part, that the present status of surgery in Canada had been one of gradual evolution from the time when the country was sparsely settled up to the present time. Being a young country, something of the spirit of the pioneer settlers had been inherited and Canadian

surgeons were more ready to develop along lines which might be new and revolutionary in character. The consequence of this adaptability and willingness to learn had been that nowhere was work in surgery done with more uniform efficiency than could be found in the hospitals of Canada to-day. Speaking of conservatism in surgery the speaker said that conservatism was good, but pure prejudice often passed as conservatism and, therefore, it was fitting that no prejudice should be harbored and that conservatism should in no way hinder our better judgment. We should preserve an open mind, abandon incorrect ideas, and "hold fast to that which is good." Scientists of old well represented extreme conservatism or prejudice and all new ideas had to undergo bitter criticism. Better equipment had enabled one to better test the validity of any claim that might be made of things new. Prejudice, however, still existed. The greater part of the speaker's address was devoted to Lister and his works, taking him as an example of the modern scientific man. Lister had difficulty in establishing the germ theory of disease for he met considerable opposition from his medical contemporaries of his own country. The speaker pointed out that, although the views of many eminent physicians were not unanimous in upholding the germ theory of disease, it was a remarkable fact demonstrating the genius of Lister that he had seldom found it necessary to recede from any position that he had once assumed. It was, too, a remarkable circumstance that foreign surgeons had been more quick to be convinced of the great value of antiseptic treatment than those of his own land. The speaker cited Lister as the possessor of the almost perfect type of the logical scientific mind, urged for students a prolonged and efficient course of instruction in the preliminary sciences, and combated the view held by many that such training was unnecessary. He regarded the fact that some of the Canadian surgeons still alive were closely associated with Lister in his life work as one of which Canadians should ever be proud. Among Lister's old house surgeons were Mallock of Hamilton, Stewart of Halifax, and Grasset and Baldwin of Toronto. In conclusion the speaker said: "I desire to emphasize the fact that we, as surgeons, are required to-day more than ever to possess the true scientific spirit. Conservatism is surely to be commended, but that type of conservatism which is tempered with an ability to use calm and deliberate judgment in determining what is best for our patients, and when new light is thrown upon some obscure problem we should be ready to abandon any erroneous ideas which we may have hitherto held and be prepared to advance, seeing no finality in our present-day methods, but always endeavoring to attain the ideal."

An address on the surgical treatment of gallstone disease was given by Dr. William J. Mayo of Rochester, Minn. The speaker said that in reviewing 4,000 operations which the Mayo brothers had performed upon the gall-bladder and the biliary passages they had been impressed with the fact that the mortality was due to the complications incident to the disease rather than to the removal of gallstones from the otherwise normal gall-bladder. Not only was the mortality greatly increased by the involvement of the deep bile passages, the liver, pancreas, and neighboring viscera, but the gall-bladder might also be found in such a condition as to render an attempt to save it impracticable and fraught with a possibility of a recurrence of symptoms. The gallstones were, however, the responsible agents in the production of these complications, inasmuch as they set up a train of events which would not have occurred had the gallstones been removed early in the history of the disease. It was in this early period that operation furnished an easy, safe, and efficient cure. Cholecystostomy with temporary drainage of the gall-bladder to the surface was the operation preferred because it saved this valuable organ for future function. The danger of reformation of gallstones after cholecystostomy was exceedingly small. In their series they observed but three cases in which stones had reformed in the gall-bladder and it was probable that in most cases of supposed reformation of gallstones the stones had not reformed, but were incompletely removed at the primary operation, an accident which did not often happen when the operation was done early. In the class of cases in which the gall-bladder was contracted down upon a mass of stones secondary carcinoma was liable to develop. In their experience two and one-fourth per cent. of all operations upon the gall-bladder and biliary tract had shown malignant complications. The danger of carcinoma alone was five times greater than the mortality following operations for the relief of simple gallstone disease. So long as the stones were confined to the gall-bladder the trouble remained local in an organ which was not essential to life, but with the entrance of stone and infection into the deep duct of the liver two fundamental organs which were essential to life were liable to be involved in the process, namely, the liver and the pancreas. Stones in the common duct not only impaired the health of the patient, but complications directly threatening life might arise at any time. In the 4,000 operations the average mortality was 2.75 per cent. In 2,920 the disease was local and confined to the gall-bladder and cystic duct. The operative mortality was 1.8 per cent. In 2,165 of these cystostomy was performed with a mortality of 1.5 per cent. In 755 cases cystectomy was performed with a mortality of 2.4 per cent. These data were contrasted with 492 cases in which the common duct was involved, with an average mortality of 8 per cent.; a mortality which depended not so much upon the operation itself as upon the extent of involvement of the liver and pancreas and the bad general condition of the patient. Pancreatitis as a complication occurred 359 times in the 4,000 cases.

The address in medicine was delivered by Sir James Barr of Liverpool in the Gallery of the Art Association of Montreal on the evening of June 8. The speaker, in addition to being a well-known British surgeon, has made for himself somewhat of a reputation as a speaker and as a wit. The title of the address was "Preventive Medicine the Medicine of the Future."

The speaker began by saying that the great advances of medical science had been of enormous advantage to individuals and had enabled innumerable persons to live who would otherwise have succumbed to the stress of circumstances, but how far that had been an advantage to the evolution of the human race as a whole was a disputable point. He claimed on behalf of the medical profession that whether they had always been right or not they had ever had been actuated by a spirit of altruism. The process of vicarious charity at the expense of the medical profession had gradually so grown that

in the present day at least, a fourth of the population of England received free medical advice. The reason why such a large proportion of the human race was being pauperized was because an inferior race was being produced. Professor Arthur Thomson had said that what children usually died of was their parents and what a nation died of was lack of men. In future medical men must not be content with treating the diseases of the community, but must also point out the lines along which the nation was to be improved by encouraging the multiplication of the fit and controlling the increase of the unfit. The maintenance of health was much more important than the treatment of disease. That prevention was better than cure was one of those half truths which readily commanded public acceptance as axioms which could not be gainsaid; but it was not nature's method and medical men were incessantly talking about following the laws of nature. The prevention of disease was very important to the individual, but when it enabled undesirables to go on generation after generation propagating their species it could be of no advantage to the race. If the public were alive to their own interests they would pay medical men liberally for directing them in the paths of truth and in the ways of health, rather than for treating their diseases. If the money which was spent in the treatment of disease had been devoted to the preservation of health, our huge hospitals would not have been half filled, the necessity for surgeons and specialists would largely have disappeared, and physicians would have been fully occupied in advising their clientèle on the preservation of health and in looking after the aged. The speaker said he was afraid we were still a long way from those halcyon days when hospital buildings would be pointed out as relics of a decadent age; but still one should at least aim at transmitting high ideals to one's successors. These ideals could be best attained by improving the stock; no environment would produce a genius. Referring to Canadians in particular, he remarked that they had a young country, a virgin soil, and they should see that it was peopled by a vigorous and intellectual race. They should shut out all degenerate foreigners as they would a mad dog. Dealing with tuberculosis the speaker said: Dr. Osler, in a recent lecture in Dublin on the fight against tuberculosis, said: "And, lastly, for our great consolation, we know that the disease is not hereditary, and for this let us be thankful." Sir James retorted: "We know nothing of the kind, although we are constantly having it dinned into our ears by medical men who ought to know better. We know that the tubercle bacillus, which is a necessary element in the production of tuberculosis, is not transmitted in the germ plasma, but the long, narrow, flat chest, delicate lungs, and feeble resisting power to the tubercle bacillus and to many other germs are undoubtedly inherited, just as much so as the shape of your nose or the color of your hair." Medical men who were shutting their eyes to the truth and encouraging matrimony and the propagation of the species by mental and physical weaklings were incurring fearful racial responsibility, and their action should be condemned in no uncertain language. Both for the prevention of insanity and consumption one should discourage and prevent the propagation of the species by mental and physical weaklings and raise up a race which would not be catching tuberculosis or anything else. While showing all possible kindness to the insane and mentally defective, they were to be given clearly to understand that with them their breed must come to an end. Insanity and mental deficiency were largely questions of inheritance. With the insane and other mental and physical degenerates prevention was certainly better than cure, but success could never be reached in either prevention of cure by maudlin sentimentality. Commenting on the large death rate from pneumonia, the speaker remarked that alcohol was a strong predisposing factor to pneumonia, because it immeasurably lowered the resisting power of the individual and increased the mortality rate. Another common cause of the high mortality from pneumonia arose from the lack of proper treatment, often owing to the fact that some medical men took two or three days to diagnose the disease and then called it congestion of the lungs, treating it carelessly as a matter of no great importance for fear of frightening the patient until the unfortunate individual was too ill to be frightened by anything. In conclusion the speaker said he was not now so much concerned with the prolongation of life as with the preservation of health. They as medical men were not concerned with any useless attainment of longevity, but with the prolongation and efficiency of life. When a life ceased to be efficient it could retire into obscurity, be withdrawn from circulation, or receive an old age pension. Alluding to Paul Bert's dictum that the aged deserved congratulations, ease and consideration, but that the prolongation of their lives did not demand any special solicitude from society, he remarked that if Bert had lived longer he would have modified his opinion. The speaker, in the course of his address, made several shrewd hits at surgeons. Among others he remarked that surgeons lived largely on the failure of physicians and he admired intensely their worth and envied their fees, which, like the falls of Niagara, were magnificent. He advised surgeons to make hay while the sun shone for fear that the millennium would arrive sooner than they expected. In reference to Ireland and tuberculosis, the speaker said: "If you abolish the tubercle bacillus from Ireland, then it will certainly become a question of 'God Save Ireland.'"

(To be continued.)

SANITATION IN AUSTRALIA.

(From Our Philippine Correspondent.)

PERTH, WESTERN AUSTRALIA, April 20, 1911.

PROBABLY nothing occasions more surprise in Australia in connection with public health matters than the small amount of vaccination against smallpox that is being done. In a country that has made such exceptional progress in supplying itself with weapons against preventable disease, it seems scarcely possible that such a vulnerable point in the public health armor should be left unprotected. The medical men of Australia have been valiantly protesting for years against such a state of affairs, but so far their recommendations have gone unheeded or such weak laws have been placed upon the statute books that nothing much could be expected from them. During the year 1909 the official records show that only 21,344 persons were vaccinated throughout the whole of Australia. No doubt quite a number were vaccinated by private physicians or for other reasons did not get into the official records, but at best these factors would not swell the total so very much. It appears that the small number vaccinated is not due to any general

or well defined anti-vaccination sentiment, but rather to general apathy. This is due to the fact that smallpox is scarcely known in Australia. In years past, due to its great isolation, it has remained virgin territory. But in more recent years it has been in frequent communication by swift vessels with the great Oriental endemic centers of the disease. So far the very efficient maritime quarantine has prevented smallpox from gaining a firm foothold. It is however too much to expect that quarantine will always prove effective and when the disease is once planted successfully upon that fertile soil many lives will be uselessly offered and probably an equally large number will go through life disfigured, all as the price for the present indifference.

In Queensland there is a vaccination act but it has not been proclaimed, and from 1901 to 1910 no official vaccinations have been reported. In New South Wales there is no compulsory vaccination act. In Victoria vaccination is indirectly enforced under the Health Act of 1890, and it is estimated that 70 per cent. of the children whose births are registered are vaccinated. South Australia has a vaccination law but the "conscientious objection" clause renders it of little value. Only 13 per cent. of the children are reported as vaccinated. In Western Australia there is a compulsory law but it has never been enforced. Tasmania has a vaccination act, but the "conscientious objection" clause makes it almost a dead letter.

In view of the fact that meat, and especially fresh meat, is comparatively very cheap in Australia, and in consequence its use probably very much more general than in any other country, it may be interesting on account of meat being frequently associated with cancer to note the incidence of this disease. In 1908 the total number of deaths reported in the Commonwealth was 46,426. Of this number 2,921, or 6.29 per cent., were due to cancer. If the population is estimated at 4,500,000 the incidence would be one death per annum in every 1,540 of the population. This rate is very much lower than that of the United States, Great Britain, or Germany.

The typhoid rate for the Commonwealth is also very low. During 1908 there were 736 deaths from this cause reported, which gives an incidence of one in 6,114 of the population.

The water supply of Australia, at its best, must be regarded as very unsatisfactory, and it is therefore interesting to note that as this is improved there is a coincident reduction in the water-borne diseases. Almost the entire continent is surrounded by a fringe of high coastal hills. The slopes toward the sea shed their water by the means of short rivers into the ocean and the water collected upon the inland slopes soon becomes lost beneath the surface of the great desert interior. To overcome such natural disadvantages it has become necessary to undertake water projects which are simply colossal when the size of the population is taken into consideration. One of the largest of these projects is the so-called "Coolgardie Water Scheme," which consists of a pipe system 351 miles long and capable of delivering daily 5,000,000 gallons of water. The water is pumped from the Helena River, near Mundaring, in Western Australia, to Bulla Bulling, which is 1,200 feet higher than the river from which it is pumped. This means that 5,000,000 gallons of water, weighing approximately 22,300 tons, are lifted 1,200 feet and propelled 351 miles. The water is first pumped into the Mundaring reservoir, which has a capacity of 4,600,000,000 gallons. In order to make the water available to towns that have sprung up along the route, twelve smaller reservoirs, with a total capacity of 31,500,000 gallons, have been constructed. The total cost of this project was over $15,000,000. The return realized from the water amounts to about $1.18 per thousand gallons. The actual cost including interest upon capital, depreciation, and operation expenses was $1.75 per thousand gallons. The annual loss, which is at present about $400,000, is borne by the government.

Lately it has been found that by means of artesian wells much of the water that disappears in the great sand wastes of the interior may be recovered. These wells have been an important factor in improving the public health and at the same time they have transformed vast barren areas into fertile land upon which valuable crops are now being grown. Practically all of these wells are over 500 feet deep and some of them reach a depth of over 5,000 feet. The average wells yield 70,000 gallons of water daily. In a few instances a daily capacity of 4,500,000 has been reached. Unfortunately much of the water is very alkaline or strongly impregnated with sulphuretted hydrogen.

The only one of the major quarantinable diseases in Australia is leprosy, and this only prevails to a limited extent. Queensland, the most of which has a tropical climate, has the majority of the lepers. Seven new cases were reported during 1910. In New South Wales there were two cases reported during the same period. The remaining states of the Commonwealth reported no new cases.

There is a federal law for the segregation of leprosy and this is rigidly enforced.

New South Wales takes care of its 23 lepers at the Coast Hospital, which is located upon the outskirts of Sydney. Here these unfortunates have excellent quarters and receive good treatment. Gynocardate of magnesia is used in ascending doses and the physician in charge believes that its use is as satisfactory as chaulmoogra oil and is much better borne by the patient.

Suprapubic Intraurethral Enucleation of the Prostate. J. B. Squier.
The Value of the Guinea-Pig Test in Genitourinary Tuberculosis. J. D. Barney and E. L. Young, Jr.
Remarks on a Forbidden Case of Cancer, Involving Tongue, Tonsil, and Pharynx, Permanently Cured by Radical Excision. M. H. Richardson.
A Case of Diabetes Treated by Feeding of Calves' Pancreas. W. N. Cowles.

Enucleation of the Prostate.—J. B. Squier states the perineal route of operation is not the ideal one. The average end results of the suprapubic operation are more brilliant than those of the perineal and postoperative incontinence of urine never occurs. The author describes his technique of performing the suprapubic operation.

Guinea-Pig Test in Genitourinary Tuberculosis.—J. D. Barney and E. L. Young state that the guinea-pig test for tuberculosis, when carefully done, is by far the most delicate and invariably accurate diagnostic weapon at one's disposal and that a negative test is of indisputable value.

Cancer of Tongue, Tonsil, and Pharynx.—M. H. Richardson reports a case of this condition permanently cured by radical excision.

Pancreas Feeding in Diabetes.—W. N. Cowles reports a case of diabetes in a man twenty-three years old, in which improvement followed the administration of

fresh calves' pancreas. Three years later the patient died from the effects of a large carbuncle of the neck, and at autopsy the pancreas was found to be represented by a fibrous cord about one-fourth the size of the normal gland.

Pseudochylous Ascites.—By F. P. Henry. See MEDICAL RECORD, Vol. 79, page 1118.

Carcinoma of the Rectum.—J. A. Blake states that in all growths necessitating the destruction of the sphincter it is preferable to institute a permanent inguinal anus and extirpate the remainder of the rectum. He has done this in fourteen consecutive cases without mortality. This he would consider the operation of choice for all cases were it not for the formation of a permanent artificial anus. It has a low mortality because there is no secondary infection of the wound, the fecal current being deflected from the site of operation. In the case of neoplasms lying above the anal canal so that it, or at least the sphincter, can be left, the competency of the latter can be even better conserved by the abdominal than by the perineal method on account of the extent of the incision and the risk of injury to the nerves in the latter operation. If the lower limit of the growth is three inches or more from the anus, the gut can be divided below the growth through the abdominal incision and the operation completed without a perineal wound other than a stab drainage opening.

Selection of Operation in Biliary Disease.—H. Lilienthal concludes that, as a rule, any gall-bladder which is worth operating on at all for biliary disease may with advantage be removed; that in the majority of cases this removal may be safely accomplished at the primary operation; that when for any reason this procedure appears dangerous or otherwise undesirable one should look forward to completing the work at a subsequent sitting, surely at the first sign of disorder of the bile passages.

Perforating Duodenal Ulcer.—By J. A. Lichty. See MEDICAL RECORD, Vol. 79, page 1025.

Alcohol Injection in Trifacial Neuralgia.—F. C. Keller states that a successful injection, or series of injections, is followed by relief for about the same length of time as that following a first resection of a peripheral nerve. Reinjection for recurrence gives a longer period of relief than a repeated resection. In cases in which it might be deemed advisable to do a resection of the Gasserian ganglion, or the Frazier operation, the injection would no doubt be a valuable preliminary treatment to put the patient in better condition for the radical operation.

Metastatic Growths of the Central Nervous System.—B. Sachs states that these provide one of the saddest chapters in all medical practice, and for the neurologist the helplessness in the presence of slight spinal symptoms seems almost mortifying. In several instances in which root pains of the lumbar or sacral plexus signalized the invasion of the central nervous system the author has been sorely tempted to ask that an exploratory operation be done to remove at least these foci of the disease, and perhaps for the time that the patient was to live to prevent the invasion of the cord itself and the subsequent paralysis and other distressing symptoms, but the surgeon is not willing—and properly so—to attempt the removal of such growths. In cases of sarcomatosis he injected Coley's fluid, but the results observed were not satisfactory.

Clothing and Regulation of Body Temperature.—H. F. Wolf states that clothing tends to make the skin more sensitive and may thus prevent the so-called "hardening." By proper hygienic measures the skin can recover to a great extent its adaptability to changes of climate. One must recommend to the public clothing which is sufficiently porous and yet does not prevent evaporation and more especially change of air about the body. Proper protection against cold should be accomplished not by heavy underwear but by suitable outer garments.

Salvarsan.—A. L. Wolbarst presents a comparative study of a case of paresis and of a case of tabes, in both of which salvarsan was used. In the former there was a decided but temporary improvement after the injection; in the latter an immediate ill effect was observed, which continued up to the patient's death twelve days after the injection.

The Academy of Medicine in Paris.—F. Dowling states that this institution is the official advisory council of the French Government in all matters pertaining to public health and sanitary science.

Prolongation of Heart Life.—W. F. Waugh states that the basal facts in the treatment of heart diseases are the reduction of cardiac duty and the regulation of the tonicity of the vessel walls.

Organized Medicine.—By J. B. Murphy. See MEDICAL RECORD, July 1, page 44.

Race and Alcoholic Insanity.—G. H. Kirby reports an analysis of 1,762 cases of alcoholic insanity of both sexes, and the racial divisions recognized were the Irish, German, Italian, negro, Jewish, and those born of native parents, all other races being lumped together under one head. He finds the largest percentage of alcoholic cases (20 per cent.) in the Irish; next comes the mixed group, with 10 per cent., followed by the German with 9 per cent., the Italian and the American with 5 per cent. each, the negro with 4 per cent., and the Jewish last with only 0.6 per cent. Alcoholic insanity was most frequent among males in all groups except Americans, where there were as many women as men.

Chronic Pancreatitis with Gallstone Disease.—J. B. Deaver states that chronic pancreatitis may be suspected of having complicated gallstone disease when the symptoms point to severe recurrent disease of the cholcdochus with marked emaciation and disturbance of the carbohydrate metabolism or evidence of insufficient action of the pancreatic ferments on the food in the intestine. The treatment is closely bound up with the surgery of the bile passages. As Mayo Robson has shown, free drainage of the biliary tract and, through this, of the pancreatic duct may in many cases enable the pancreas to cast off the infection.

This is the principle of the treatment. The best cure, however, is prevention by prompt surgery in biliary diseases.

Traumatic Tetanus.—E. N. Liell reports a case of tetanus following a pistol wound in a boy aged ten years, in whom recovery followed the use of 55,000 units of tetanus antitoxin.

Influenzal Meningitis and Its Serum Treatment.—S. Flexner describes the results obtained by Martha Wollstein. (See page 131.)

The Ether Rausch.—W. T. Coughlin describes this method of producing brief general anesthesia by the administration of ether with very little air.

Arm Traction Splint.—A. A. Crane describes a new splint for producing traction and counter-traction in the treatment of fractures of the humerus.

Renal Calculus.—H. A. Kelly describes a transrenal plan of nephrolithotomy which, except in the simplest cases, with an easy exposure, is, he believes, quicker and safer than pyelotomy or any other transrenal operation.

Diaphragmatic Hernia.—B. V. Caffee reports a case of diaphragmatic hernia following a stab wound. Operation was successful.

X-Ray Plate Changes.—S. Lange describes a device for the rapid changing of plates for taking stereoscopic pictures of the chest.

Blood-Counting Apparatus.—M. B. Katzenstein describes a vest-pocket case for carrying the pipettes and solutions necessary for making a blood count.

Carbuncle.—C. L. McDonald reports a case of carbuncle occurring in a diabetic, which was successfully and rapidly treated with the aid of an autogenous staphylococcus vaccine.

Sodium Cacodylate in Syphilis.—J. H. Long reports unfavorable results from the use of this drug in three cases of syphilis.

Dry and Wet Test-Meals.—By A. F. Chace. See MEDICAL RECORD, Vol. 79, page 1025.

Gunshot Wound of Chest.—F. G. Dyas reports a case of this condition in which the abdominal findings were those of peritoneal injury with marked distention, tenderness, and pain. Upon opening the abdomen no lesion was found.

The Lancet.

Why Samuel Pepys Discontinued His Diary. D'Arcy Power.
The Significance of Pus in the Anterior Chamber. J. H. Parsons.
Salvarsan and Mercury in the Treatment of Syphilis. H. C. Ffrench.
Wassermann's Reaction in Relation to Cancer. A. Foerster.
A Case of Appendicitis Illustrating the Necessity of Early Operation. D. D. Malpas and P. de Lostalot.
Chloretone in Seasickness. D. A. Welsh.
A Case of Hydatid of the Uterus. A. E. Giles.
A Case of Infantile Paralysis in a Girl Aged Five Years. Treatment by Electricity and a Specially Devised Boot with Concealed Supports. F. Hernaman-Johnson.
The National Insurance Bill and Preventive Medicine. H. M. Richards.
Sir Charles Bell and the Functions of the Fifth Nerve. A. D. Waller.

Why Samuel Pepys Discontinued His Diary.—D'Arcy Power states that hypermetropic astigmatism was the cause which led Pepys to end his diary prematurely at the age of thirty-six.

Pus in the Anterior Chamber.—J. H. Parsons states that hypopyon is always of serious import; that the prognosis is fair if the cause is merely exogenous toxic absorption, bad if exogenous bacterial invasion. In endogenous infection, whether syphilitic or septic, the prognosis is better even in cases of actual bacterial invasion, but much irretrievable damage is often done to the eye, with consequent serious defect of vision.

Salvarsan and Mercury.—H. C. Ffrench believes that salvarsan is far inferior to mercury in the treatment of syphilis.

Wassermann Reaction in Relation to Cancer.—A. Foerster states that as an active etiological factor syphilis plays a small rôle in cancer, if any at all. Epithelioma of the tongue is far more frequently preceded by syphilis than any other form of cancer. The right to place lingual cancer among the parasyphilitic lesions, next to tabes and general paralysis, must be questioned. It is possible to prepare an antigen extract for Wassermann's reaction from purely cancerous material. A serodiagnosis of cancer on the lines of Wassermann's reaction is at present not possible.

A Case of Appendicitis.—D. D. Malpas and P. de Lostalot report a case of perforative appendicitis in which the subjective and objective symptoms were exceedingly mild.

Chloretone in Seasickness.—D. A. Welsh reports the good effects in seasickness of chloretone given in doses of 5 to 10 grains.

Hydatid of the Uterus.—A. E. Gales reports a case of this condition.

Poliomyelitis.—F. Hernaman-Johnson reports a case of this condition in a child treated by means of electricity and a specially devised boot with concealed supports of steel.

National Insurance Bill and Preventive Medicine.—H. M. Richards states that the national insurance bill proposes to arrange for the compulsory insurance of every third person in the United Kingdom against sickness and disablement. He suggests a scheme by which the necessary medical organization in the area of each county or county borough would include medical referees to check malingering, medical attendants in midwifery emergencies, medical and surgical consultants attached to a clinic, a sanatorium physician, a laboratory director, and domiciliary attendants on the insured. In the author's opinion such a staff can best be organized by combination with the medical departments of the county and county borough councils. This would combine economy with efficiency for both the public health and insurance services.

Sir Charles Bell and the Function of the Fifth Nerve.—A. D. Waller states that the gross misunderstanding about whether motor and sensory applies to the fifth nerve proper or to the entire fifth inclusive of the nerve of mastication was, and still is, a confusing circumstance in the discussion of the motor and sensory functions of the fifth nerve. It plays quite a conspicuous part in the early days of the University of London.

An Address on the Early Recognition and Prevention of Carcinoma of the Stomach. J. Sherren.
Acute Jejunal Obstruction in a Case of Advanced Pregnancy; Operation; Recovery. E. A. Roberts and F. C. Wallis.
Treatment of Appendicitis in Children. W. A. Rees.
Pyocyaneus Infection in Dogs and Its Similarity to Rabies. W. F. Harvey, R. M. Carter, and H. W. Acton.
A Case of Blackwater Fever in England. J. Rooth.
The Rapid Treatment of Gonorrhea. A. C. Magian.

Prevention of Gastric Carcinoma.—J. Sherren states that considerably over a third of the cases of carcinoma of the stomach originate in chronic ulcers and are therefore preventable.

Acute Jejunal Obstruction.—E. A. Roberts and F. C. Wallis report a case of this condition occurring during advanced pregnancy. Operation revealed the obstruction high up; there was no volvulus, band or adhesion, but merely a flattened piece of intestine, which was not inflamed or kinked.

Appendicitis in Children.—W. A. Rees believes that in the child, with the same degree of acuteness of onset as in the adult, the case is more likely to go on to form an abscess than in the adult. The less done in abscess cases the better; opening and simply draining an abscess cavity can often be done in ten minutes and is most frequently all that is necessary.

Pyocaneus Infection and Rabies.—W. F. Harvey, R. M. Carter, and H. W. Acton have found that infection with the pyocyaneus bacillus occurs in dogs and that this infection may, both as regards symptoms produced and tests applied, lead to confusion with rabies.

Blackwater Fever in England.—J. Rooth reports a fatal case of malarial hemoglobinuria occurring in a young male three weeks after his arrival in England from Burma.

Rapid Treatment of Gonorrhea.—A. C. Magian describes a treatment for gonorrhea which he claims will effect a cure in five days. The patient is given copious irrigations with a solution of potassium permanganate, distilled water, and solutions of protargol, chloride of gold, sulphate of zinc, and nitrate of silver. The patient also uses injections of protargol and urethral bougies of protargol and antipyrine.

June 12, 1911.

Bacterial Anaphylatoxins.—Neufeld and Dold believe that bacterial anaphylatoxins throw light on the nature of infectious processes. Bacteria form their own special toxins, which are more or less specific for the particular germ during its life. From dead bacteria soluble endotoxins are also set free. But, aside from these specific products, others are formed at times which are nonspecific in character and which do not, like the specific toxins, produce antibodies. Much of the clinical picture of infection is due doubtless to these anaphylatoxins. The formation of the latter is antagonized by bacteriolysis and phagocytosis. This conception of anaphylaxis does not exclude other sources for the latter. Thus in anaphylaxis from the use of antisera we may infer that the anaphylatoxin is produced in the formation of the antibody and without the intermediation of the bacteria. However, in the author's opinion, the anaphylatoxin in such cases originates remotely from the latter.

Unilateral Atrophy of the Lung.—Döblin and Biernath describe two cases of this very rare congenital anomaly and give the meager literature of the subject. The nature of the affection is obscure. It appears to represent an agenesia and yet may be due in part to a congenital bronchiectasis. The state of the lung does not differ essentially from that due to a frank obstruction of the bronchi in earliest infancy. It is also known that, given a congenital atelectasis of the lung, bronchiectasis develops secondarily from attempts of the lung to expand. The two patients were in advanced middle life. One had been dyspneic for many years, a sufferer presumably from asthma and emphysema. She had recently gone through pneumonia, which brought her under observation. Despite all evidence of absence of lung tissue in the right half of the thorax, there was none of the retraction which follows destructive disease of the lung parenchyma. As the patient lives an accurate diagnosis can hardly be made, but in the opinion of the best authorities the total absence of deformity is tantamount to the presence of a congenital aplasia of the lung. The sound lung was much hypertrophied and the heart pushed to the right. The second was an autopsy case. The man had complained of his chest for about two years only. The diagnosis was congenital bronchiectasis with aplasia of the right lung, compensatory hypertrophy of the left lung with emphysema, persistent foramen ovale, and a general hypertrophy with dilatation of the right heart, with failure of the circulation, as shown by serous effusions and stasis in the abdominal viscera. The pulmonary vessels showed degenerative changes with venous thrombosis. There was congenital narrowness of the aorta. In these cases the Röntgen shadow should aid materially in the diagnosis.

Suprarenal Bodies in Laennec's Cirrhosis.—Dominici gives a full account of our knowledge of the histology of the adrenals in this affection. We know that the disintoxicating activity of the liver must be compromised by a disease like Laennec's cirrhosis, and it is evident that compensatory activities must be invoked. Since the adrenals have a marked disintoxicating function it is important to study them in this disease. But since naked eye anomalies are not always in evidence we must needs make a careful research for functional aberrations and especially for histological changes. The author investigated five cases from this point of view. The most significant changes appeared to indicate a hypofunction of the medulla in four cases. In the other case there was hyperfunction, which comes in relation with the fact that this patient, unlike the others, had arteriosclerosis. In all the cases there were evidences of cortical hyperfunction, believed to be compensatory in character. The medullary hyposecretion is believed to explain some of the phenomena in the hepatic cirrhosis, notably the diminished vascular tonus, which cannot be explained on purely mechanical grounds. This was, of course, excluded in the arteriosclerotic subject. The cytological examination is naturally very complicated, many color tests requiring employment. The chromaffin tests could not be made on account of the age of the specimens. That there was hypofunctioning of the medullary cells was evidenced by the numerous appearances of degeneration, including the presence of numerous fat droplets. Hyperfunctioning cells in both cortex and medulla were indicated by an exaggeration of the characteristics of the normal cells.

Münchener medizinische Wochenschrift.

June 13, 1911.

The Ovarian Hormone as the Cause of the Growth of Uterine Myoma.—Seitz invokes the hypothesis of a pathological ovarian hormone as the natural exciter of the growth of uterine myomata. That the latter are arrested by castration is, of course, well known, and it is also well understood that the ovary possesses a principle—or principles—which stands in close relationship not only to menstruation and uterine hyperplasia but also to the growth and nutrition not alone of organs which constitute secondary sexual characters but to other organs which bear no known relation to sex. The author believes that the same principle which presides over the increase of the muscle fibers of the uterus in pregnancy is also responsible for the growth of uterine myomata; but that in the latter case the hormone is no longer physiological but the product of a diseased ovary. This conception of hormone action is somewhat novel, but the original definition of hormones is such that it can be made to include any principle derived from an organ which when taken into the blood can modify the action of a remote organ. This view brings us at once to the subject of the causation of neoplasms in general. Hypothetical chemical substances have already been postulated as causes of tumors, for example, the attraxines of Fischer. To return to uterine myomata, their tendency to increase in size during pregnancy is well known, as is also the opposite tendency to improve even as soon as the puerperium. The favorable action of the *x*-rays on myomata appears to be due to their destructive action on the ovaries.

Nutrition with End Products of Protein Digestion.—Frank and Schittenhelm speak most hopefully of great possibilities in connection with nourishing the sick with the presumably easily utilized end or near end products of albumin digestion, which may be employed by the rectum as well as per os. Animal experiment has been made to show the eminent practicability of the idea, some results being styled as brilliant. It is assured that the end products are fully equal in food value to a definite quantity of natural albumin; that they are well tolerated, and highly

palatable. Exact details are not supplied, and it is not denied that the idea is being commercialized and that some of the great German manufacturing houses are about to introduce food preparations of this sort for exhibition by mouth and rectum respectively.

Diagnosis of Variola.—Paschen makes an important communication on the diagnosis of smallpox with especial reference to differentiation from chickenpox. Four years ago he discovered in both vaccine lymph and variola virus, as well as in the virus of sheeppox, certain minute corpuscles with special tinctorial properties. He has since tested a great variety of exudative cutaneous lesions for these bodies, but always with negative results. In the Brazilian epidemic of 1908 Prowazek and Aragao rediscovered the same corpuscle and learned incidentally that the virus of the disease does not pass through colloid filters. These bodies are apparently none other than Guarnieri's vaccine corpuscles (*Cytoryctes*). However, the vexed question of the specific cause of variola is beside the mark, for in this connection the author is merely considering a method for differentiating variola from varicella. With the natural improvements in technique which have accrued from the labors of those who have studied these corpuscles the author feels sure of his ability to diagnosticate or exclude variola by the presence or absence of the latter. Of six apparent cases of variola occurring recently in his vicinity the diagnosis was readily made by ordinary clinical methods in three. In the others the resemblance to varicella was notable. The diagnosis was readily established by the discovery of the corpuscles, and it was possible to isolate the patients and vaccinate the exposed at a very early date. These patients were elderly men unvaccinated since childhood, who contracted variola of the mild type.

Treatment of Recent Infantile Paralysis with Recumbency and Immobilization.—Mayer reports two cases treated in this manner. Any curative management must combat the inflammation, hyperemia, hemorrhages, and leucocyte migration and thereby prevent the sclerosis of the anterior motor ganglia. Recumbency and immobilization favor this fortunate termination in some manner. They clearly protect the cord from reflex insults and antagonize the contractures. The treatment was first described by MacKenzie, an Australian, in 1909, and soon afterwards the author called the attention of his German colleagues to the paper. Since that time plaster-of-Paris casts and the plaster bed have been tested. The method is best understood through a case recital. One of the author's patients, aged 2½ years, was attacked in January, 1910, with pains in head, back, and limbs, and high fever. On the following day all the limbs and trunk were paralyzed, the pains increasing in severity. In about a week the arms recovered their function. The pains, however, had not abated and the possibility of spondylitis was entertained. The case was seen on the twelfth day and the lower extremities were at once immobilized in plaster-of-Paris, the chief indications being the prevention of contracture and the already beginning equinus. After four weeks of immobilization the muscular functions were seen to be improving. Treatment continued until July, when patient was allowed to get up. Aside from a mild paresis of the tibialis anticus, the musculature was quite normal. The slight impairment in the gait could be noted only by the trained observer.

Specific Treatment of Tricophytosis.—Bruck and Kusonoki of Prof. Neisser's clinic have been making use of the so-called tricophytin—the toxin-like substance obtained from cultures of the tricophyton—in the treatment of the cutaneous lesions caused by that parasite. The latter was cultivated on a special medium and the culture filtered. After making sure of the sterility of the filtrate phenol was added as a preservative. The possibility of a diagnostic cutaneous reaction is being separately investigated. The therapeutic use of tricophytin is by intradermic injection. Thus far but few cases have been treated. One was an instance of severe ringworm of the beard which had resisted *x*-ray treatment and epilation (röntgen epilation) as well as the use of parasiticides. A diagnostic intradermic injection was made with tricophytin from two separate strains of fungi. The seat of injection was the upper arm, and positive results were obtained (fever, local irritation). The lesions of tricophytosis were not affected by the tests. Nevertheless, on the following day these lesions began to improve and disappeared in a surprisingly short time. He was discharged cured on the fifth day. The diagnostic test, repeated, was still positive. While it is not expressly so stated, this remarkable therapeutic result appears to have been due to the accidental outcome of a diagnostic test. The reaction set up by the tricophytin in the sound skin was marked in severity, both locally and constitutionally. The erythematous area about the puncture was as large as the palm, and the funtion of the arm was somewhat interfered with. The fever persisted for several days, and was accompanied by malaise, prostration, and headache. The reaction from the second injection was also notable, although somewhat weaker. The authors are unable to explain the rationale of the therapeutic result.

Bacterial Cause of Chronic Urethritis.—Von Wahl has for some years made a study of chronic gonorrhea with regard to its contagiousness. In 1904 he published an article on the bacteria of the normal urethra with especial emphasis on gram-positive and gram-negative flora. He has been able to follow up certain cases of gonorrhea bacteriologically for years. That in chronic cases we do not often find gonococci, but ordinary pyogenic cocci, has indeed long been taught, but we have not known to what extent the latter have acted independently in causing sequelæ. The author's researches tend to show that certain streptococci are able to set up chronic urethritis without previous gonorrhea, and that they are capable in association with gonococci of causing a mixed infection of the urethra. Finally, the majority of cases of chronic, as distinct from acute, urethritis are due to streptococci. The author's results also tend to show that the accused streptococcus is not the familiar *S. pyogenes* but a special form of coccus. It is admitted that in a small percentage of cases chronic urethritis is due to the staphylococcus. The streptococcus of urethritis greatly resembles the gonococcus. The author has differentiated it from the diplo- and streptococci previously found in the urethra. The author appears to have demonstrated that under certain conditions his urethral streptococcus can behave much like the gonococcus, *i.e.* it can set up an acute, contagious discharge, and can also give rise to the various local complications of acute gonorrhea, together with arthritis. Under ordinary conditions the streptococcus does not cause complications beyond chronic prostatitis and rarely epididymitis. It does not lead to cystitis or metastases.

Mental Development of the Young.—Moxom states that it has been said that the foundation of most mental disorders occurring in adults is laid in childhood and adolescence. However this may be, it is certainly true that among the ever-increasing number of our asylum inmates and among the larger number outside who suffer with various forms of psychoneurosis many are found who owe their condition in large measure to the fact that they have not learned, when young, how to lead self-controlled and efficient lives.—*New York State Journal of Medicine.*

Insurance Medicine.

SUGGESTIONS TO MEDICAL EXAMINERS.

By THE INSURANCE EDITOR.

Tact and Judgment.

The rules of ethics and policy play an important rôle in examining for life insurance, and an observance of them, as far as circumstances allow, will not only smooth the path of the examiner but help satisfy the other parties concerned. It will not be out of the way, therefore, to offer a few suggestions on these lines before taking up the subject from a purely medical point of view.

The two attributes, tact and judgment, are invaluable assets to every professional and business man, and are particularly useful when a physician is acting in the capacity of medical examiner. Success has only too frequently come to those who, though deficient in medical training and skill, have been the possessors of these admirable qualities; and then others, though adequately equipped and brainy, have not prospered because they would not or could not handle their clients and fellowmen with the requisite amount of tact and judgment. The successful life insurance examiner most highly appreciated by his company is the one who, while quick, skillful and firm in his decisions, retains the respect and good will of the applicant and agent through his courtesy and ease of manner and who, furthermore, can be counted upon to calm the ruffled feelings of an irritated applicant or regain the good will of a discontented policy holder.

The management of the average applicant is a delicate proposition, for as a rule he does not seek life insurance and has probably yielded to the persuasion of the agent after a long and persistent struggle. Later on he is apt to be thankful at what he considers his own foresight in throwing this protection about his family, but, for the time being, he may be very reluctant in submitting to the examination—not anxiously seeking it as an examiner will sometimes suppose. Even if he had any enthusiasm in the beginning, his ardor may become chilled at any stage during the preliminary steps required before a policy can be placed. The examiner has little opportunity for previously studying the mood of each applicant, of knowing whether he is to meet a willing or unwilling subject, and he should, therefore, take it for granted that each case will present its individual difficulties and that the subject may be more or less sensitive to brusque or impatient treatment. The applicant may go further and display an unwilling and disobliging spirit; at such a time it is doubly important for the examiner to be diplomatic rather than show signs of irritation and perhaps cause the agent to lose the business. The strong, able examiner always keeps absolute control over his feelings, no matter how provoking the circumstances may be, whereas the weak will give way. The wrong word from an examiner in an unguarded moment has cost the agent the loss of many long days, even weeks, of trying, arduous work. An examiner should always remember that there are others—the company and the agent—whose financial interests in the matter are greater than his own, and for this reason he ought to ignore the occasional inconvenience and trouble he may encounter. Furthermore, it should be his endeavor to leave the applicant and agent good friends to himself and the company, even when it is his unpleasant duty to give an opinion adverse to their interests, for not only will he then serve the company better, but, also, will add to his own popularity in the community.

Notwithstanding what has been stated in regard to the importance of keeping up agreeable relations with the agent, it should always be distinctly understood that the examiner is to elicit a full history from and make a careful examination of the applicant without allowing the agent to interfere or intrude to the slightest degree. A company cannot conserve the interests of its many policy holders without insisting on careful work by impartial and uninfluenced examiners and on rigidity in selection. The examiner must be decidedly firm in this respect, and his ability to do so and at the same time remain on pleasant terms with the agent and applicant correspondingly increases his value as a medical representative of the company.

While in a general way, tact, and judgment should be observed at all times, they are especially called for whenever some unavoidable emergency interferes with promptness in keeping the appointment as to time and place, in propounding the many pointed questions in regard to personal and family history, in inquiries concerning the use of alcohol and drugs, when requesting the applicant to remove sufficient clothing to allow a thorough examination, in the examination of women especially when interrogating them about the functions and diseases peculiar to their sex, and in procuring subsequent additional information.

The examiner with small experience may hesitate to completely carry out some of the requirements through fear of upsetting the mental equilibrium of the applicant. That all the demands and queries can be made when diplomacy is employed and not give rise to irritation, is proved by the experience of the carefully picked examiners on duty at the home offices. They come in contact with applicants only found in the large centers —the leaders in industry and finance, powerful and forceful—men having heavy demands on every minute of their time, and accustomed to rule their fellow beings. They are difficult to approach, and it would be natural if they chafed in submitting to the full requirements which are invariably exacted by these examiners. Yet, the latter, through their quick appreciation of what is fit, proper and right, secure the cooperation of the applicant and carry out their mission thoroughly from beginning to

Insurance.—(See page 130.)

Albuminuria of Adolescents in Its Relation to Life Insurance.—(See page —.)

National Insurance Bill and Preventive Medicine.—(See page 141.)

The Apparently Unchanged Death Rate Within Recent Years Among Risks Insured in This Country Under Ordinary Policies.—James D. Craig suggests that the decrease in general mortality within recent years does not appear to be caused by any marked improvement in longevity among the people who insure under ordinary policies, but is confined almost exclusively to the industrial classes. Mr. John K. Gore, actuary of the Prudential Life Insurance Company, presented a paper to the Fourth International Congress of Actuaries in which he showed a death rate of 28.3 per cent. during the years 1851-1863, as against 21 per cent. during the years 1889-1901, which is a decrease of 730 deaths for each 100,000 of the population. From a comparison of the records of different companies, or of the different records of a particular company, the same general conclusion is reached that the improvement in the mortality of ordinary risks during the last generation has not

been material, while among the population it has been conspicuous, and the question immediately arises, is this condition being continued to-day? Is the mortality of the industrial masses still improving, while that of the ordinary classes remains constant, or are both classes improving? Within the last few years the decrease in the death rate among industrial lives has been marked. On the whole, a comparison of the tables of various insurance companies seems to show that American mortality among the ordinary class of insured is not improving, although Craig admits that the evidence in this direction is not conclusive. At the same time, when each little result points to a similar conclusion, the suggestion is very striking. It may be that while medicine, surgery, and science have been combating fevers, tuberculosis, etc., the prosperous condition of the country has been producing a state of nervous activity among many business men, which tends to increase the death rate; or possibly the intense competition for new business has caused companies to accept more risks among the residents of southern countries, or more risks which a generation ago would have been considered inferior, with the result that the standard has been reduced.—*Proceedings of the Twenty-first Annual Meeting of the Association of Life Insurance Medical Directors.*

Acute Articular Rheumatism and Insurance.—Loser objects to a circular from the Gotha Life Insurance Bank, directing special care in insuring applicants with a history of acute articular rheumatism, even in the absence of cardiac disease. He considers that complete recovery from the disease and even occasionally from a cardiac defect may take place, though general opinion is against the latter possibility. Loser reminds physicians of the time when recovery from tuberculosis was considered impossible. Leyden, Senator, Fräntzel, Gerhardt have all mentioned the possibility of cure of a valvular lesion by absorption of infiltrations and compensatory enlargement of the healthy portions of a valve. Loser has recommended several applicants, refused by other examiners, all traces of alleged valvular lesion having disappeared; he has never had any reason for regretting such recommendations. If the diagnoses in such cases were not absolutely sure then a diagnosis of a valvular lesion should not be taken every time as seriously as is the custom nowadays. Loser has seen the disappearance of all signs of an aortic insufficiency in one case and of a mitral in another; the aortic lesion may have followed syphilis, the mitral, however, followed an attack of acute articular rheumatism in childhood.—*Blätter für Vertrauensärzte der Lebensversicherung,* March and April, 1911.

The Statistical Method in Medicine.—H. Selfe Bennett discusses the difficulty of comparing statistics, in many instances the impossibility of so doing. He shows that, owing to advances in pathological science, many of the figures, for instance of the returns of the Registrar-General of England and Wales, have from time to time to be "finally" adjusted, and are thus incapable of comparison with those of past decades. The author confesses himself as being anti-statistical and contends that the statistical method, undeniably necessary and fundamentally important as it is for a wide survey, is often unsuitable to its purpose in medical details, not only because of the intrinsic difference between the two kinds of mind employed, but also on account of the natural complexity of the facts dealt with. He positively asserts that "collective investigation" so far as medicine, though not perhaps surgery, is concerned is a failure and that all our classifications of natural phenomena, whether in the mass or in detail, are merely working hypotheses, theories invented for use, but not an immutable and infallible system.—*Transactions of the Life Assurance Medical Officers' Association,* London, 1910.

Accident and Apoplexy.—Kutner details the history of an applicant for accident indemnity, who hit his head against an iron support while lifting a heavy piece of steel. One week later he showed evidence of cerebral hemorrhage or thrombosis occurring in the right cerebral hemisphere. The symptoms included partial paralysis in the region of the third cranial nerve, disturbance in the motor functions of the left upper and lower extremities, and tendency to fall toward the left side. To bring an accident in connection with a cerebral hemorrhage or thrombosis, it must be shown that the injury was considerable enough to produce clinical symptoms at the time or shortly afterward. The applicant's injury was not serious enough to be noticed by a fellow-worker at the time, and he continued his work, though later he said he had felt ill while doing so, for several days afterward. Physical examination showed a disease of the mitral valve, which could easily have led to an embolus with subsequent cerebral thrombosis. If the accidental injury had anything to do with favoring such an embolism, the latter would have occurred immediately after the accident. Kutner's decision in this case was that any connection between the accident and the applicant's condition was improbable.—*Zeitschrift für Versicherungsmedizin,* April, 1911.

Danger of Marital Infection in Tuberculosis.—As early as 1898, Gollmer of Gotha showed that in such cases of marital infection as have come to the notice of life insurance companies, the person last infected has even before marriage shown a predisposition to the disease. In 1906 Ruge of Berlin was able to confirm this conclusion. Married applicants, therefore, exposed to infection because of tuberculosis of the wife or husband, may, it is asserted, be accepted for insurance, especially if the applicant is found to have no predisposition to the disease so far as heredity, history, and physical examination show. As illustrating the absence of danger in such cases, the writer gives the history of one applicant whose first wife died of tuberculosis and whose second wife was likewise afflicted; he personally showed no signs of infection and no predisposition to it. He was insured and married a third time after the death of his second wife. He lived to an advanced age and died of heart failure, having escaped all infection during his intimate association with two tuberculous persons.—*Blätter für Vertrauensärzte der Lebensversicherung,* January and February, 1910.

Expert Opinion in a Case of a Paranoid Form of Dementia.—Eschle reports in full a case of this disease, with results of expert examinations. The article is not adapated for abstracting.—*Zeitschrift für Versicherungsmedizin,* March, 1911.

Workmen's Accidents.—According to certain figures recently published by the French Ministry of Labor, the number of accidents arising out of employment and giving rise to incapacity lasting over four days was 389,249 in 1910, or an increase of 8 per cent. over the figures of 1909. This increase is noted in all forms of labor with the exception of cutters of precious stones and bakers. The industry in which the greatest number of accidents was reported was that of metallurgy, a proportion of 277 accidents for each 1,000 men so employed. Stone workers had 156 accidents per 1,000 employed, ordinary metal workers 149 per 1,000, and laborers in the chemical industry 143 per 1,000. English statistics, so far as they are available, support these figures. The dangerous trades, so far as accidents to ordinary workingmen are concerned, must, therefore, be considered those in which—as in metallurgy, for example—ordinary laborers are put to certain work, which, although not skilled labor in the strict definition of the term, is yet of a nature to demand special aptitude and a certain amount of training. How far the law of cause and effect rules in these accidents is not as yet fully known. There are many points of great interest connected with what may be called the physiology of certain skilled and unskilled trades, and it is time that science devoted some consideration to these points. It is considered desirable that medical men should pay more attention to the study of the problems of labor than they have hitherto done.—*The Hospital.*

Book Reviews.

The Dawn of the Health Age. By Benjamin Moore, M.A., D.Sc., M.R.C.S., L.R.C.P. Price, $1.40. London: J. and A. Churchill; Philadelphia: P. Blakiston's Son & Co., 1911.

This volume is devoted to a discussion of some of the problems that are just now confronting the rank and file of the medical profession; some of them also concern the men "higher up." The chapters are entitled: How we tinker with disease instead of stopping it; the follies of our present public health service, the doctor and his patient in private practice and in state practice; our hospital systems, their evils and abuses; the warfare with the great white plague; and the evolution of the national medical service. The book makes interesting reading, and many of the conditions mentioned are present also on this side of the water. Much of what the author has to say about the abuse of the hospital system and the trials of the club doctor will bear thinking over. There is no party politics in the book, and no muck raking; but the absence of these only adds to the value of the volume.

Joint Tuberculosis. By Leonard W. Ely, M.D.; Consulting Orthopedist to the County Hospital; Attending Orthopedist to the Children's Hospital, Denver, Col.; Member of the American Orthopedic Association and of the American Medical Association; Associate Fellow of the New York Academy of Medicine; formerly Surgeon to the Sea Breeze Hospital; Consulting Orthopedist to the Roosevelt Hospital; Consulting Orthopedic Surgeon to the Metropolitan Hospital, New York, etc. Illustrated. Price $2.50 net. New York: William Wood & Company, 1911.

The subject of joint tuberculosis is one that touches closely many branches of medicine and surgery. It interests not only the orthopedic surgeon, but also the general surgeon, the internist, and the pediatrist. It is a subject, nevertheless, that has not been accorded an intensive scientific study commensurate with its importance, and very few works have been written dealing with this subject exclusively. The present volume represents the most recent contribution to this very scant literature, and, in addition to its thorough presentation of the most advanced knowledge of joint tuberculosis, it enables the author to publish for the first time the results of his original investigation into the pathology of this disease. This is a phase of the subject that has been sadly neglected by former writers. Emphasis has been laid chiefly upon the clinical aspect of tuberculosis of the joints, and practically nothing has been contributed within recent years to the knowledge of its etiology and pathology. The author deserves credit for the years of patient laboratory investigation that has enabled him to formulate an ingenious hypothesis of the pathogenesis of bone tuberculosis. The researches that led up to this hypothesis are described in minute detail and are illustrated by means of a large number of excellent photomicrographs. According to this theory the tubercle bacilli after gaining access to the body are carried in the lymph channels to a node where the lymphoid cells wage battle for their destruction. If this battle is unsuccessful the bacilli leave the node accompanied by their natural antagonists, the lymphocytes. The fight may be resumed at the next node, and the bacilli and lymphocytes may finally reach the blood. In the red marrow of the bones the battle is renewed. In this tissue, rich in lymphocytes, the latter gather to the attack and form the initial tubercle. If the lymphocytes prevail, the disease is arrested without causing any symptoms; if not, it goes on to the production of joint tuberculosis. The author advances the theory that joint tuberculosis is the result of Nature's effort to rid herself of the disease, and is essentially an excretory process. Moreover, the accepted relation of the lymphocyte to the tubercle bacillus is at least not invariable. It is assumed that the lymphocytes and certain other similar cells are not Nature's defensive organism, but the natural food of the tubercle bacillus. This would explain why the tubercle bacilli thrive so well in the bone marrow. An operation causes the disappearance of red or cellular or lymphoid marrow in the ends of the bones, and thus shuts off the food supply of the bacilli. If secondary infection be added, the resulting suppuration furnishes the supply of cells peculiarly adapted to the growth of the tubercle bacilli, and tuberculosis invades the yellow marrow also. The author does not carry this theory further, resting satisfied that it explains all of the phenomena of bone tuberculosis. This theory is a most ingenious one, and is valuable particularly because it rests upon a firm foundation of laboratory investigation. In addition to this original feature, this volume presents the other important phases of joint tuberculosis: its etiology, symptomatology, diagnosis, differential diagnosis, prognosis, and treatment. Chapters on these subjects comprise the first section of the work. Those on diagnosis and differential diagnosis are particularly thorough. The second section of the book takes up in order the special forms of bone tuberculosis, as of the spine, hip, knee, ankle, wrist, etc. There is a chapter in the appendix on "Some Pathological Processes in Tuberculosis," by Dr. Gerald Bertram Webb. A large number of case histories are also appended. The volume is illustrated with many *x*-ray photographs and photographs of microscopic preparations, apparatus, and patients. The excellence of these illustrations and of the typography, paper, and binding, forms a fit setting for Dr. Ely's work.

Principles and Practice of Modern Otology. By John F. Barnhill, M.D., Professor of Otology, Laryngology, and Rhinology Indiana University School of Medicine; Otologist and Laryngologist to Deaconess and State College Hospitals, etc., and Ernest de Wolfe Wales, B.S., M.D., Clinical Professor of Otology, Laryngology, and Rhinology Indiana University School of Medicine; former assistant in Otology Harvard Medical School; former assistant Aural Surgeon Massachusetts Charitable Eye and Ear Infirmary, etc. With 314 original illustrations, many in colors. Second edition, thoroughly revised. Price, $5.50. Philadelphia and London: W. B. Saunders Company, 1911.

It is four years since the appearance of the first edition of this work, and the favor with which it has apparently been received, and recent advances in the science of otology have necessitated the preparation of a new edition. In this the high character of the former edition has been maintained, with the following important additions: The chapter on the examination of the function of the ear includes the uniform system of tests accepted by the Eighth Otological Congress at Buda-Pesth in 1909; a more extended statement regarding operative injury to the facial nerve; a description of the conservative radical mastoid operation, commonly called the Heath operation; several paragraphs relating to the symptoms, pathology, and surgical treatment of labyrinth suppuration. In the preparation of this book the authors have succeeded in their aim of modernizing the subject of otology, of correcting certain traditional beliefs, of advocating the earliest possible prophylaxis or treatment, of emphasizing the importance of a thorough examination and definite diagnosis as a basis for rational treatment, and of thoroughly illustrating the text. The text is conspicuously clear and direct in statement, qualities which particularly commend this book to student and practitioner alike. The large number of admirable illustrations combine with the excellence of type, paper, and binding in making this book a representative one among the many modern masterpieces in medical book making.

Disease of the Pancreas. Its Causes and Nature. By Eugene L. Opie, Professor of Pathology, Washington University, St. Louis, Mo., formerly member of the Rockefeller Institute for Medical Research and Pathologist to the Presbyterian Hospital of New York City. Second edition rewritten. Illustrated. Philadelphia and London: J. B. Lippincott Company, 1910.

When the first edition of this volume appeared, some seven years ago, it excited a great deal of interest because it contained among other things one of the first systematic attempts to connect the clinical syndrome of diabetes with a definite lesion in the pancreas. A great many papers followed the appearance of the book, some favoring the author's views, others showing that the lesions in the islands of Langerhans were not constant even in well-marked cases of diabetes. The original material investigated was small. In the new edition the author has collected a much larger number of cases and has examined them in the light of more recent knowledge. The result is a position somewhat less dogmatic as to the occurrence of a definite type of lesion in diabetes. Experiments on animals have also shown us that other organs play an important part in the pathogenesis of diabetes. In the light of this new lore the revision of the various chapters has necessarily been extensive, the literature being cited down to 1909. Hemorrhagic pancreatitis, fat necrosis, chronic interstitial pancreatitis, calculi, cysts, and tumors are among the subjects treated. The chapter on the pathology of the pancreas in diabetes mellitus contains the results of a recent summary by Cecil of ninety cases of diabetes. A short section on hemochromatosis completes the best work in English on the pathology of the pancreas.

Society Reports.

AMERICAN THERAPEUTIC SOCIETY.

Twelfth Annual Meeting, Held in Boston, Mass., May 11, 12, and 13, 1911.

(Special Report to the MEDICAL RECORD.)

THE PRESIDENT, DR. HARVEY W. WILEY, OF WASHINGTON, D. C., IN THE CHAIR.

Thursday, May 11—First Day.

AT the opening session the annual reports were presented and obituaries of two ex-Presidents of the Society were read by the Secretary, Dr. Noble P. Barnes, of Washington, D. C.; that of Dr. Howard H. Barker, of Washington, having been prepared by Dr. D. Olin Leech, and that of Dr. John V. Shoemaker, of Philadelphia, by Dr. James M. Anders.

Report of Committee on Competitive Therapeutic Research.—The Committee on Competitive Therapeutic Research, Dr. Reynold Webb Wilcox, of New York, Chairman, reported that no essays had been sent in in competition for the annual prize of $100. Subsequently the Council voted to offer $200 for the prize of 1912. This competition is limited to members of the Society, and the subject is limited to a substance or preparation which is official in the U. S. Pharmacopœia. The research work reported may be either wholly laboratory or clinical, or laboratory and clinical combined.

Address of Welcome.—This was delivered by Dr. Clarence J. Blake, of Boston, representing the Harvard Medical School, and the response was made by Dr. Wilcox.

Address of the President: Bromatotherapy.—Dr. Wiley said that diet was an important factor in the prevention of disease, and could also be made so in its treatment. Excessive production of tissue, especially adipose tissue, was in some respects just as much an effect of disease as the loss which we associated with most diseases, and disease which resulted in hypertrophy could often be controlled by diminishing the amount of food. On the other hand, to combat the exhaustive waste of tissue attendant upon many diseases, and stimulate anabolism, food of a proper kind was one of the most valuable resources of the physician. Dietetics as related to the treatment of disease was discussed by the speaker in a variety of aspects, and one section of the address was devoted to the subject of alcohol. A bitter controversy, he said, had been raised over the question, is alcohol a food? Again the respiration calorimeter has come to our assistance in this matter, and it had been shown by Atwater and his assistants that the average adult human organism is able to oxidize with practical completeness about three ounces of alcohol per day, if the ingestion is distributed over different periods of the day. The old idea that if one is going to make unusual exertion or be exposed to extremes of climatic conditions the body should be fortified by alcohol had disappeared. It was quite certain now that the taking of alcohol did not make one any less apt to freeze, but more so, and that it did not produce any such amount of energy as to be at all compensatory for the injury it might otherwise cause. On the witness stand he had stated that he considered alcohol a food because a certain quantity of it was burned in the body, resulting in the production of heat and energy. In the light, however, of recent investigations, and from theoretical considerations, he was inclined to the opinion that the effort to rid the body of alcohol, although only in the small amount mentioned, perhaps consumed much more energy than was furnished by its combustion, and that upon the whole alcohol could not be regarded as a food, even in the limited sense referred to. Without question it was a substance which did not nourish the body, build tissue, or repair waste, and it was quite likely that its value either as a food or medicine had been greatly overestimated. The susceptibility to certain diseases in persons addicted to alcohol had been noted by many writers, while the records of death by sunstroke showed that a very large percentage of the victims were alcoholics. Dr. Reid Hunt, in a paper on the effect of nitrils on small animals, reported that mice which had previously been given alcohol were much more susceptible to toxic influences than those which had not. The tendency which alcohol undoubtedly had to weaken the body resistance was not a matter to be left out of consideration. The general result of the study of this problem had been an accelerated movement to restrict the use of alcohol in medical practice, and especially hospital practice. A few years ago some alcoholic beverage was regarded as necessary in the treatment and elimination of the causes of disease. Now, however, both as a means of preventing disease and as a remedy for disease, it was rapidly falling into disuse, and it seemed likely it would become a mere memory in the materia medica and in the pharmacopœia. The causative effect of alcohol in the production of insanity had been recognized by most authors, though all were not agreed upon this question, and the same was true in regard to cirrhosis, which many writers attributed solely to the consumption of alcoholic beverages. That alcoholism in parents influenced unfavorably the mentality, morality, and physical characteristics of the offspring seemed to be a well-recognized fact. The question therefore naturally arose whether there was any further necessity for the use of alcohol except for tecnical purposes.

The Delusion of the Stimulant and Tonic Effects of Alcohol.—Dr. T. D. CROTHERS of Hartford, Conn., read this paper. Thirty years or more ago alcohol was considered a stimulant and tonic, and was used freely without question or doubt, while the textbooks of that and earlier periods urged that it was indispensable as a therapeutic agent. The modern physician regarded with astonishment the theories and delusions of the past, in thus mistaking the action and effects of alcohol, and was equally surprised to note that some physicians and authors of eminence still adhered to these erroneous ideas. Exact research and a study of the facts of the case had now convinced the great mass of the profession that physiologically alcohol was a depressant, anesthetic, and narcotic. As early as 1845, when it was beginning to be used as the great stimulant drug in disease, a number of observers denied its stimulant properties, and in the sixties and seventies several English physicians asserted the same. Laboratory work began about this time, and here the researches showed that the claims of its value were unsupported. Kraepelin of Heidelberg assumed that if the physiological action were that of a stimulant or tonic, such effect could be most readily seen in a study of the senses, and his carefully conducted experiments showed that in no instance did alcohol increase the acuteness of the senses, but, on the contrary, had a depressant effect on them. Thus, the sight, hearing, smell, taste, and touch were all deranged and lowered to an extent measurable by instruments of precision. There was an exactness in this study which could not be gainsaid, and similar experiments were carried on by various observers. One of these studies was a measurement of the muscular output of laborers and others with and without small doses of alcohol. In all instances irritant effects were noted at the first. The heart's action was increased and the blood-pressure raised, and there was an apparent increase in muscular power, but this was convulsive and of short duration, and was followed by marked depression; so that the output was greatly lowered, instead of being increased. Many studies were made to determine the action of alcohol on the brain and nervous system. The

ability to discern impressions on the senses and to reason as to their significance was found to be always lowered. There were slowness of thought, loss of ability to recognize sudden unusual conditions, and enfeeblement of memory. The heart's action was increased, and with it the cerebral circulation. From this there resulted more or less confusion and lack of clearness and power of concentration. The apparent stimulation was simply irritation, and not increased power or capacity. One very large and carefully conducted experiment was made with typesetters in a government office in Germany, where the results of small doses of alcohol, given at intervals, were increased errors, lessened work, greater fatigue, and measurable anesthetic action. A great variety of similar experiments, with the same results, had also been made in this country. It was a curious fact that a large part of the literature regarding the value of alcohol as a stimulant and tonic was based on tradition, superficial views, and unsupported personal opinion. The teachings of prominent authors had been accepted without question. Thus, Todd, Bennett, and other clinicians who extolled the stimulant properties of alcohol made an army of converts, who unhesitatingly accepted their conclusions, and even to-day physicians of the older school insisted that these early teachings were correct. One of the first breaks in this delusional evidence was furnished by mortality statistics showing a higher death-rate under the use of alcohol as a stimulant. Dr. Crothers spoke of its employment in pneumonia, diphtheria, tuberculosis, and other affections, and said that many papers in this country had called attention to the fact that alcohol was a very dangerous drug in collapse states, particularly following typhoid fever. Here, while there would be an apparent resuscitation for a short time, the depression which followed resulted in more profound collapse. Like other delusions in medicine, founded on misconception and false reasoning, this idea of the stimulant quality of alcohol continued tenaciously and died very slowly; but theories and traditions of the past could no longer be accepted unless they were in harmony with the teachings of science in the laboratory and at the bedside.

Dr. A. D. Blackader of Montreal said he could not deny that under certain circumstances he still found alcohol of some value. There was no question that Trousseau and some of the older authorities used it in too large quantities, but he did not believe that the time had yet arrived when this agent should be banished from our pharmacopœias.

Dr. F. E. Stewart of Philadelphia agreed with Dr. Blackader that alcohol was undoubtedly a valuable remedy in certain cases.

Some Observations on Vaccine Therapy.—Dr. E. W. Nagle of Boston said that, to secure an active vaccine one must have a virulent type of bacteria, these must be killed at the correct time, before they began to lose their cultural characteristics, and it was essential to subject them to the lowest degree of heat for the shortest possible time necessary to kill them. The question of dosage was a difficult one. The speaker did not depend upon the opsonic index, but relied entirely on the clinical symptoms. Usually the beginning dose was a small one: ¼ of 1 c.c. (150,000,000 in the case of staphylococcus vaccine); increasing to ½ c.c., ¾ c.c., and then 1 c.c., and continuing with this dose if there had been marked improvement. Sometimes it was necessary to increase the dose to 2 c.c. before there was improvement. In cases in which it seemed imperative to bring the patient quickly under the influence of the vaccine the dose was not increased gradually, but after the first small dose a large one was given at once. In cases where vaccine was administered oftener than twice a week smaller doses were given. The injections were given in the arm, alternating right and left in order to give the site of the injection the longest possible time to recover from the soreness. Chronic suppurative ear cases appeared to be especially amenable to vaccine treatment, but Dr. Nagle had not met with the same success in nose cases.

Friday, May 12—Second Day.

Dioxydiamidoarsenobenzol as a Patented Product.—Dr. F. E. Stewart read this paper. We were told, he said, that Ehrlich made an arrangement with a German manufacturing house by which this house furnished him with the money required to carry on the 606 experiments which resulted in the discovery of the drug named, with the understanding that if a product was obtained of sufficient value to warrant its commercial introduction it was to be patented, and the patent controlled by the manufacturing house. The speaker expressed the opinion that the arrangement thus made represented a plan of cooperation between professional and commercial interests which, if purged of the monopolistic feature now pertaining to it, might be made in every way commendable. Medicine, including pharmacy, was an altruistic profession. Its object was to prevent disease and heal the sick; not to exploit the sick-room for gain. Cooperation between the medical and pharmaceutical professions and the great manufacturing houses with that end in view meant progress, but such cooperation must include control of the pharmaceutical arts by licensed practitioners of medicine and pharmacy, and compliance with rules for the advancement of pharmaceutical science. The following summary was given by Dr. Stewart: 1. The object of the patent law being to promote progress in science and the useful arts, it logically follows that its proper application to materia medica products will promote progress in materia medica science and the arts of preparing medicines and applying the same to the healing of the sick. As now applied, however, the patent law hindered progress in the knowledge of drugs as therapeutic agents and injures the professions of medicine and pharmacy. 2. Product patents were monopolies granted to persons who were not required to be interested in promoting science or in advancing the arts of medicine and pharmacy. 3. Progress in materia medica science and in the pharmacological arts was dependent upon the cooperation of those engaged in the practice of the pharmacological arts and in the results of the publication of their researches for the benefit of science. 4. The position assumed by certain members of the medical profession, that it was immoral for physicians to make money out of the sale of drugs, was unwarranted. The wrong was in carrying on what ought to be a professional business in a commercial manner. 5. Materia medica products could not be properly introduced to science without using the educational machinery of the profession, namely, medical societies and the press. When products were controlled by commercial introducers their introduction to science by the cooperative work of the profession was impracticable, because the opening of the medical journals and societies to their discussion would convert the educational machinery of the profession into a great advertising bureau for the exploitation of monopoly. 6. Most of the experimental work necessary for determining the value of new therapeutic agents was carried on in hospitals, dispensaries, and other charitable institutions. When the results were appropriated by commercial houses for building up monopolies beneficence was turned into commercial exploitation, a crime against humanity. 7. Under a system of competition it was safe to open the educational institutions and their laboratories to the manufacturers of materia medica products, and ask their cooperation in developing the science of materia medica. 8. Under the system of product patents maintained in this country the

medical journals were forced to give the manufacturers advertising space which millions of money could not purchase; being compelled to do this in order to keep up with the foreign journals in publishing important news.

Chronic Acetanilide Poisoning; Describing a Definite Symptom Complex as a Result of Its Continuous Ingestion.—Dr. H. C. Gordinier of Troy, N. Y., read this paper, the conclusions which he drew from his study of the subject being as follows: 1. Chronic acetanilide poisoning was productive of the following perfectly definite and easily recognized symptom complex—chronic cyanosis, cardiac insufficiency, a distinct blood-picture showing profound disorganization, and definite renal changes. 2. The acetanilide habit was much more common than was generally supposed, and enslavement by it was comparable with or worse than that by opium or alcohol. 3. Acetanilide had a special predilection for the cardiovascular system, acting as a virulent hemolytic agent.

Dr. C. E. de M. Sajous of Philadelphia said that in his experience cases of acetanilide addiction were not so difficult to manage as those of opium addiction. He called attention to the constriction of the arterioles produced by the coal-tar products, as demonstrated by experimentation, and expressed the opinion that this was the chief cause of the cyanosis.

The Uses and Limitations of General Anesthesia as Produced by Subcutaneous and Intravascular Injections.—Dr. W. Wayne Babcock of Philadelphia referring to Burkhardt's method of inducing anesthesia by the intravenous injection of chloroform and ether, said that chloroform soon had to be abandoned, but ether was still employed to a limited extent, especially in Russia. In the 75 or 100 cases now on record there had been one death and several instances of pulmonary embolism. The method was not therefore to be recommended. He then went on to speak of the production of anesthesia by the subcutaneous injection of narcotics, which, he said, was a revival of a very ancient use for these agents. It was not, as a rule, well adapted for children, but in adults he had met with a very fair measure of success with it. In 10 per cent. of the cases in which it was tried he had found it possible to induce complete anesthesia, with abolition of the reflexes, and in from 50 to 60 per cent. sufficient anesthesia for operative purposes, though without entire abolition of these. The drugs employed were of three classes: (1) hyoscine or scopolamine; (2) morphine and apomorphine; (3) alcohol and similar agents. In regard to apomorphine, he was convinced that its main action was that of a sedative. It was therefore a terrible mistake to administer it in cases of narcotic poisoning, as was sometimes done. The method which Dr. Babcock had found most satisfactory was to give a subcutaneous injection of ⅛ grain of morphine with 1/100 grain of hyoscine or scopolamine, and also an enema of decinormal salt solution containing from 1 to 3 ounces of alcohol. In fifteen minutes the hypodermic injection was repeated, if necessary, and in fifteen minutes more a third injection might perhaps be required. When apomorphine was employed, only a very slight emetic effect, or none at all, had been noted. Objections to this method were, first, that as a rule it was not suitable for abdominal operations, and, second, that if toxic products were present in the system the narcotics would tend to retard elimination by closing up the emunctories. It was an ideal method for operations about the mouth, throat, and nose, where ether proved dangerous and unsatisfactory, and when it was used we could often dispense with tracheotomy. It was essential to watch the breathing of the patient very carefully, and sometimes it was necessary to pull the tongue forward.

Therapeutic Value of Sodium Cacodylate.—Dr. Spencer L. Dawes of Albany, N. Y., said that, at the meeting of the American Therapeutic Society in 1907, he had read a paper by Holmes C. Jackson and himself entitled, "The Physiological Action, Elimination, and Therapeutic Application of Sodium Cacodylate, Used Hypodermically," and as certain authorities had so emphatically insisted that sodium cacodylate was possessed of no arsenical properties whatever, he gave a summary of the findings then reported in order to demonstrate the incorrectness of such statements. He also stated that many of these findings had been confirmed by Runnels and other observers. He then went on to say that it was generally accepted that the value of arsenic as a therapeutic agent, where indicated was limited only by its toxicity, evidenced mainly in the gastrointestinal tract, and, in his opinion, herein lay the justification for the use of sodium cacodylate hypodermically; for the experiments made had shown that much of that drug was changed into inorganic arsenic and was stored in the tissues and utilized as rapidly as it could be taken care of, without effect upon the mucosa of the digestive tract. Experience had taught him that in giving small doses, with intervals of non-treatment, he had erred on the side of prudence, and that in most instances satisfactory results could be obtained only by using relatively large doses daily, without intermission and often several weeks. This was especially the case in anemias of long standing. There had been reported to him 14 cases of pernicious anemia treated with this agent. Of these, 4 patients had short periods of improvement alternating with exacerbations, and finally died. Of the remaining 9, reported as cured, 5 had been so recently discharged that they could not be claimed as having yet positively recovered. He had records of 410 cases of simple anemia treated by himself and others, and in every uncomplicated case there had been complete recovery. He had yet to see an instance of anemia in which the administration of this salt has not markedly, and usually quickly, increased the percentage of hemoglobin and, as a rule, the red cells. His records showed 22 cases of neuritis treated, with 16 recoveries. One patient with tic douloureux of six months' duration recovered; another improved and then was not benefited Of 17 patients with eczema, most of them of squamous type, 15 were cured. Twenty-two subjects of psoriasis were treated, with but 9 recoveries, while several were apparently aggravated. Neuralgias and gastralgias responded favorably in almost every instance, and certain types of malaria, such as are seen in former residents of tropical and semitropical regions, gave the most remarkably quick and permanent response. Sodium cacodylate had proved much more satisfactory in the treatment of chronic rheumatism than other forms of arsenic, and in one case rheumatoid arthritis had apparently been checked by its use. In the administration of the drug it was most important to secure a perfectly pure salt free from arsenous oxide. He had established for his own convenience an arbitrary standard of one milligram for each pound of body-weight to start with, gradually increasing the dose to 0.2 gm., and frequently to 0.3, and he felt sure that the failures to get results were more often due to insufficient dosage than to any other cause. It would appear that this salt was of service in the same class of cases as arsenic, and, because of its non-toxicity, it was far more desirable in many cases where large dosage was indicated. In conclusion, Dr. Dawes said it had seemed to many clinicians that if dioxydiamidoarsenobenzol was of value in syphilis, theoretically sodium cacodylate, being less toxic and having a slightly larger percentage of arsenic, ought also to be of value. That this reasoning was fallacious had been very tersely stated by Nichols. Since December, 1910, Dr. Dawes had received reports on the use of sodium cacodylate in various forms of syphilis from many observers, and many cases

had been reported in the medical journals. While in some instances there had seemed to be satisfactory results, the greater number of observers reported it of no value, and he was inclined to believe they were correct. If it were used, however, he thought that massive doses (0.6 gm.) should be employed, in order to overwhelm the spirochetes, if possible.

Dr. Gordinier reported that in tabetic pains he had seen remarkable relief afforded by the intramuscular injection of sodium cacodylate.

Epithelial Conductors and Obstructors.—Dr. Robert T. Morris of New York said that the chief obstructor of the development of epithelium on raw surfaces was peroxide of hydrogen, a substance now in universal use throughout North America. Next to it in this regard, and also next most commonly employed, was gauze; and the third most destructive agent for young epithelial cells was some form of ointment. Then came the so-called protective coverings, such as guttapercha, which allowed culture media to collect underneath. At 10 o'clock the next morning one might see all these obstructors put into use in every hospital in the country. Among conductors of new epithelium one of the most remarkable was the moist skin of an egg, which some of the old surgeons used to believe actually carried a vital principal. Other good conductors were animal membranes, like Cargile membrane, silver foil (much used at the Johns Hopkins Hospital), and oiled silk (if properly sterilized). Substances which were entirely impervious were conductors to a very limited extent if cut into strips and employed with great care. These might be said to be on the borderline between conductors and obstructors.

Diabetes Mellitus from a Surgical Standpoint.—Dr. Alfred King of Portland, Me., said there was a time when surgery was defined as that part of the healing art which required manual or instrumental means in the treatment of disease. The surgeon, however, never had been and never would be a mere tool, for he had to deal with processes calling for the finest training of the mind, the most complicated study, the most conscientious, strenuous, and heroic efforts. In diabetes it was essential that there should be a careful and complete examination of the urine and a study of its changes, a consideration of the metabolic changes taking place in the fluids and tissues of the body, especially as regards nutrition and the processes of repair, and also a general examination, including the blood, blood vessels, emunctories, and the power of resistance. Gangrene, which was generally due to arteriosclerosis, often called for surgical treatment, preventive, palliative, or operative. In the lower extremities the process might affect only one or more toes. In such cases if the line of demarcation formed early, if the adjacent parts were not inflamed, and if there was a good pulse in the posterior tibial artery behind the internal malleolus and in the dorsalis pedis, the removal of the dead portion alone might be sufficient. If, however, the line of demarcation formed slowly, if the foot were inflamed, and if the pulse in the arteries mentioned were but feebly felt if at all, operations on the foot were harmful. In such cases the amputation should be above the knee. The diabetic might require any kind of surgical procedure. Because of his disturbed metabolism, impaired nutritive and reparative processes, reduced resistance, and depressed nervous system, the most careful consideration for the patient was called for, and also the most skilful application of the principles of surgery in the treatment of wounds. If, however, proper precautions were taken, and the patient were properly prepared beforehand, a large proportion of diabetics could be operated on as safely and satisfactorily as other individuals. It was very evident that diabetics presented various types and that the term diabetes mellitus conveyed no definite concept to the surgeon or physician. When it was said that diabetes contraindicates certain operations, some more definite reason should be given. Diabetics presented a number of different types or groups besides acute, subacute, and chronic, or mild and severe cases. It was well for the surgeon to classify them, even though the dietetic or other treatment might change them from one class to another. These cases should be considered in the class to which they belonged at the time of the operation. They might be divided into two general classes, one containing those having glucose only in the urine, and the other, those having both glucose and the acetone bodies in the urine. The first class might be subdivided into still two other classes, one in which the glucose came from the carbohydrate foods ingested, the other in which sugar persisted when carbohydrate and proteid foods were restricted. The first class of cases varied very much as to the amount of carbohydrates which could be taken without glycosuria. Sometimes the omission from the diet of sugars alone was sufficient to remove the glycosuria, and sometimes a slight limitation of the starch, as well, would produce the same result. Dietetic and other treatment for a time might produce a still further tolerance for starch. This class of cases, and it was a large one, offered little, if any, contraindication to any operation. The second class of these cases, under dietetic and other treatment, might have but a small amount of glucose in their urine, and generally were unconscious of any impairment of health. With careful attention, they bore operation well. The other general division, embracing those cases with both glucose and acetone bodies in the urine, might be subdivided into three classes. The first included those cases in which the acetonuria was due to improper diet. The starch taken was insufficient; but if the amount of starch was increased the acetone bodies disappeared, and these patients should then be considered as belonging to the other class of diabetics. The injury done by the improper diet was relieved in a short time, and these cases also, after a brief treatment, showed but little disturbance under operative procedure. The second class included those cases in which the glucose and acetone bodies were due not only to foods taken, but to changes in the body-tissues themselves. These cases were of a more serious character, though changes in adipose tissue were of less grave import than those in the muscular tissue. In such cases the general condition of the patient, the nature and need of the operation, and the amount of ammonium carbonate in the urine should be taken into account in deciding upon an operation. The third class was a more severe form of the second, and had urine containing glucose, acetone bodies, and a markedly increased amount of ammonium carbonate. They were the most serious of the cases; yet much could be done to put them into the other classes, and, if possible, this should be accomplished before operating. The condition of the kidneys should not be lost sight of in this connection, and the knee-jerk should be tested, as its absence indicated impaired functional activity or sclerotic changes in the central nervous system. The matter of preparing a patient for operation was worthy of careful consideration. The circumstances of the case might permit of no preparations except those directly connected with the operation itself, but fortunately this was rare. When there was time for preparation the most serious mistake made was to put the patient on a carbohydrate-free diet for a few days, with the idea of getting the excessive amount of glucose out of the blood. It was not realized that by this course mild cases were made worse, and that severe cases were made much worse, and might even be brought into a state of coma with fatal termination. The best method was to put the patient to bed for a few days, as rest lessened food requirements and the activity of tissue changes. Water should be freely given to dilute the poisons in the blood and promote their elimina-

tion. In the way of food, starch, to the amount of three ounces in twenty-four hours for each 150 pounds of body-weight should be allowed. Sometimes one food acted much better than others, but it was generally advisable to use a variety at this time. The amount of each would depend upon the percentage of starch. For proteins, beefsteak, chicken, and eggs might be employed, and for fats, beef fat, oleomargarine, or olive oil. Celery, radishes, lettuce, and cabbage formed good green stuffs, and for drinks, water, tea, and coffee without sugar, brandy, whisky, or wines might be given. For a tonic, strychnine sulphate, 1/30 grain every four hours, and when there was edema some form of iron was advisable. Thirty grains of sodium bicarbonate every four hours was helpful, and if there was much acidosis it should be given every two hours. When the acidosis was severe it was better to avoid butter and cream. For laxatives, rhubarb and soda, cascara, castor oil, and mercurials were serviceable. Water alone, freely taken for twelve hours before the operation, favored elimination, and was attended with benefit from lessened metabolism. Ether was the safest and best anesthetic to use. After the operation care should be taken to add to the diet the minimum amount of starch required as soon as possible.

Hypodermic Medication; Its Advantages and Technique.—Dr. J. Blake White of New York said it was not the intention of his paper to add to our knowledge of this subject, but rather to emphasize the value of a more general use of the hypodermic method and a proper recognition of the various details essential to success in its practice. These, we all knew, were too frequently disregarded, a neglect which resulted in detriment to the patient, if not in effects that greatly detracted from the usefulness of this system of treatment. His paper no doubt would appear rather elementary to those who regularly practised subcutaneous injection, but there were others to whom these details might naturally seem not to be of sufficient importance to warrant the very careful attention which they really required. If we paused a moment for reflection we would see that all the most certain results obtained to-day with therapeutic agents were achieved through this method of applying them, and it was natural to suppose that this already wide field would in the future be still further developed and enhanced in value.

Saturday, May 13—Third Day.

Remarks on the Treatment of Chronic Disease.—Dr. J. Madison Taylor, Philadelphia, presented personal experiences and convictions in treating cases of chronic or protracted diseases and disorders. He laid stress on the fact that the body was not made up of various detached and independent pieces like an insentient machine, but consisted of one living entity, in which all the parts depended for maintenance of integrity upon (1) the physiological interdependence of each part upon the whole; (2) the efficient cooperation of all those mechanisms or systems which contributed to the vital processes, among which were (*a*) the noble organs, (*b*) the systems, nervous, circulatory, digestive, respiratory, genito-urinary, not forgetting the practical compensatory functions of the skin and muscles, all whose actions must be encouraged and enhanced; (3) the autoprotective forces, consisting chiefly, as made clear by Sajous, of the adrenal system (adrenals, thyroid, pituitary), and (4) the whole dominated by the psychomotor and other machinery of consciousness. To secure best results in protracted disorders which constituted complex blends of disordered thinking, feelings, and willing, along with depression or exaltation of function and structural disintegration, it was important to reach not only an actual diagnosis of the major pathological states, but also a relative estimation of the functional integrity, *i.e.* the vital status of the individual. No matter what the organic or other tissue damage, or the kind, degree, or curability of the more obvious morbid processes, it was usually entirely possible to secure such mitigation of distresses, disabilities, or even structural disintegration, by rational and general therapeusis, as would prove gratifying. It was even possible to go far toward holding in check these losses in vital equilibrium. He showed how these desirable results could often be obtained, how relative cures could be effected by consistent and persistent employment of simple, rational procedures, included under the term "reconstructive personal hygiene." He urged that clinicians make a diagnosis of the status of the potential equilibrium, as well as of the specific pathological status, not neglecting either. The treatment indicated included customary measures, and also a more faithful scientific study of collateral factors, which contributed to uniformity in well being, physiological harmonies. The only way to do full duty to sufferers from lingering maladies was to give them every available opportunity for reaching a higher level of mental and physical efficiency. This could be done, often to a surprising degree, by measures well enough known, but too often inefficiently applied, because the clinician had omitted to attain skill in their application or direction. Dr. Taylor showed from his own experience how use could be made of a number of forceful measures available in any home, by any physician, which not only conserved and enhanced the pleasure of living contracted lives, but added much to the power of specific medication. To do so it would seem important that the clinician become familiar with neuropathology and also psychopathology in order to attain skill in broader lines of diagnosis, based on these and on physiology; also with the use of efficient auxiliary or rational measures, some of which were usurped by irregular practitioners.

The Treatment of Chronic Universal Perihepatitis.—Dr. Reynold Webb Wilcox of New York read this paper. Since Pick published his article, in 1896, this affection had usually been known as Pick's pseudocirrhosis. Rokitansky was the earliest to recognize the condition, in 1842. The anatomical characteristics were a chronic adhesive pericarditis and enlarged liver, with ascites; although the autopsy might show other pathological conditions in addition, as pleurisy, peritonitis, hepatic cirrhosis, and red and nutmeg atrophy of the liver. The usual symptoms were pain and fulness over the liver and enlargement of the abdomen from ascites, which, however, was not accompanied by edema of the lower extremities. Jaundice was commonly slight and might be absent. The pericarditis usually escaped recognition. The ascites was significant in its amount, rapid recurrence, and its apparently slight effect on the general health. The large number of paracentesis operations which might become necessary was notable. The identification of the disease was not difficult if one was posted as to its characteristics. It was not, however, described by systemic authors, as a rule, and although his first patient had been under observation for some time previously, Dr. Wilcox did not recognize the disease until he read the work of Pick. As yet the etiology was uncertain, although various infectious diseases might precede the onset. Modern pathologists were inclined to ascribe the causation of chronic obliterative pericarditis, as well as of similar conditions in other serous membranes, to the tubercle bacillus; yet all instances of this disease were certainly not of tuberculous origin. It was true, however, that the terminal lesions might be tuberculous. Symptoms resulting from the pericarditis might be insignificant or entirely absent, but those from the perihepatitis and peritonitis were striking. The ascites usually called for paracentesis, which might have to be repeated indefinitely. That the physical condition of the patient remained good under these circumstances should be a valuable hint as to the correct diagnosis. The measures advised in the treatment of

hepatic cirrhosis were of comparatively little service because the lesions were largely perihepatic or, at least, were not hepatic until very late in the disease. The methods of treating plastic pleurisy in vogue were applicable, as also those for adhesive pericarditis, if this were recognized. In the acute exacerbations, which might appear very alarming to one not familiar with the disease, Dr. Wilcox, after considerable study and experimentation, had found that antipyrine salicylate, given in ten grain doses every two to four hours, would relieve the symptoms and shorten the attack. Failing a definitely known causation, although this condition always suggested an infection, the treatment should be based upon experience and that, indeed, was based upon the limited number of examples likely to be encountered.

Hypoadrenia as a Cause of Death in Infections, and Its Treatment.—Dr. C. E. DE M. SAJOUS of Philadelphia said that by hypoadrenia he meant that form of adrenal insufficiency which occurred late in the course of a febrile disease, as a result of the exhausting secretory activity, probably aggravated by temporary local lesions, to which the adrenals were subjected during the early or febrile stage of the diseases. In lobar pneumonia and bronchopneumonia, for instance, resolution might be considerably delayed, and convalescence likewise. Late in the case there were extreme adynamia and a low blood pressure, the temperature was below normal, the pulse was weak and rapid, and death from heart failure was not infrequent. In typhoid fever hypoadrenia was commonly observed, the disease assuming what was now known as the cardiac type, with, late in the case, extreme prostration, a rapid, weak, and sometimes irregular pulse, hypothermia and a marked tendency to vertigo, fainting, and cardiac failure. As stated by Morichau-Beauchant, the adrenals seemed to show a special predilection for certain infections. This was particularly the case as regards diphtheria. If at the end of an infectious disease the patient, instead of going on to convalescence, remained in a condition of asthenia, with low blood-pressure and temperature, there was good reason for the assumption that terminal hypoadrenia had occurred. The secretory activity of the adrenals having been inhibited by their exhaustion during the acute process, these symptoms resulted from inadequate oxidation of, and metabolic activity in, the tissues. The patient complained of chilliness, and the surface of the body was pale owing to the poverty of the blood in cellular elements and hemoglobin, as well as to recession of the blood-mass to the deeper vascular trunks. Anorexia, nausea, diarrhea, and more or less frequent fainting spells might be concomitant symptoms in such cases, which were markedly exposed to relapse or to sudden death from heart failure. Various complications of infectious nature were also liable to occur, since the immunizing processes were greatly weakened through the deficiency of adrenal secretion. In short, the body was rendered vulnerable to the attacks of almost any pathogenic organism. Disorders of nutrition, cholelithiasis, and even Addison's disease likewise might appear. In the special type in question no adrenal lesion might be discernible. In the majority of instances, however, the organs were congested and enlarged, and might show here and there a limited hemorrhagic area. Occasionally they were the seat of suppuration, especially when the causative disease was, or included, a streptococcic infection, pneumonia, or meningitis. In these cases the use of adrenal gland or of pituitary body, which acted very similarly though with less violence and more lasting effects, sometimes gave surprising results. The adrenal product supplied precisely what the body needed, the resumption of all oxidation processes. This meant the restoration of general metabolism and nutrition and a rise of blood-pressure which caused the blood to circulate normally in all the organs. Indirectly it increased the contractile power of the heart, which was thus rendered capable of projecting the blood with more vigor through the lungs, causing more complete oxygenation of the blood. From these features alone considerable benefit was derived, but from the assistance of the immunizing action of the adrenal secretion we had also the added factors of the freeing of the blood from any intermediate (and therefore toxic) wastes, bacterial toxins, etc., it might contain, and of the increase of phagocytic activity. Kirchheimer and others had used large doses of the adrenal active principle hypodermically in the collapse of pneumonia, diphtheria, and scarlet fever. A better plan, Dr. Sajous believed, was to inject it with saline solution (at 108° F.) intravenously, the needle of the syringe containing it being attached to the rubber tube of the saline solution apparatus. Such measures, however, were indicated only in emergency cases. In the average case the glandulæ suprarenales siccæ of the U. S. P., administered by the mouth, were fully as effective if a good preparation was obtained as soon as asthenia and low blood-pressure appeared. The powder in 3 grain doses, gradually increased to 5 grains, three times a day, usually sufficed. When the cardiac adynamia disappeared the addition of a small dose of thyroid, with iron and strychnine, hastened convalescence.

The Treatment of Leucemia with the Mixed Toxins of Coley.—Dr. RALPH C. LARRABEE of Boston said that five cases had been previously reported and he had now to report thirteen additional ones, nine of his own, three of Boldoff's, and one of Coley's. Under this treatment the general condition of the patients, some of whom had been treated with the *x*-ray without benefit, usually improved markedly, and in many instances there was a very marked diminution in the number of leucocytes. In other cases the leucocytes did not diminish, though the general condition improved. It was noticeable that while the myelogenous cases were often benefited, the lymphatic cases showed no improvement. This mixed toxin treatment was to be regarded as merely palliative, not curative; but in many instances it added greatly to the comfort of the patient, and no doubt prolonged life. It should not be forgotten, however, that it was a dangerous treatment and ought therefore to be employed with the greatest caution.

Malignant Endocarditis in New York City; a Study.—Dr. THOMAS E. SATTERTHWAITE of New York read this paper. (See page 109.)

Dr. F. E. STEWART of Germantown, Pa., said that one of the most important parts of the paper was that in which Dr. Satterthwaite referred to bacterial therapy. Three factors were always to be considered in relation to the use of bacterins and sera as therapeutic agents, namely: (1) the nature of the infecting germ or germs; (2) the character of the bacterium or serum employed; (3) the amount and interspacing of the doses. First, in regard to the nature of the infection. We were beginning to realize more and more that many cases of disease caused by pathogenic bacteria are mild infections. It was not enough to say, "Use antistreptococcic serum for streptococcic infection." There might be other pathogenic germs present. In a recent case of meningitis in Philadelphia in which Dr. Stewart advised the use of antistreptococcic serum, because examination of the spinal fluid apparently demonstrated the cause of the meningitis to be a streptococcic infection, postmorten examination revealed the presence of the *Bacillus tuberculosis*. The patient improved under the antistreptococcic serum, and no streptococci were found after death, but the primary infection was evidently by tubercle bacilli. Second, the character of the serum or bacterium. In the treatment of streptococcic infections with antistreptococcic serum it was always necessary to use a polyvalent serum, and the same thing was true in regard to streptobacterin. There were many varieties of strains of streptococci, and we should use a serum or bacterin prepared from strains

of streptococci identical with those causing the pathological condition in our patient. This was an argument in favor of autogenous vaccines; but the use of these was not always practicable, and autogenous sera did not exist for many obvious reasons. Polyvalent, as referred to a bacterin for example, meant that the suspension contained bacteria of the same species, but from many different sources. The bacteria used for its preparation should not only be all streptococci, but streptococci obtained from a great variety of human infection. The same principle applied to the preparation of a serum. Manifestly, better results would be obtained from polyvalent antistreptococcic serum than from one not polyvalent. In reporting the results of bacterial therapy this should be borne in mind. Mixed bacterins should be employed in mixed infections unless an autogenous vaccine was used. A mixed bacterin was one containing the various bacterial species generally present in a mixed infection. A mixed gonorrheal infection might show the presence of no less than seven kinds of bacteria. Third, in regard to the amount and interspacing of doses. Dr. Barton Cook Hirst, who had had much experience with a certain brand of antistreptococcic serum, had told him that it was essential to use at least 100 c.c. in twenty-four hours to obtain the brilliant results frequently secured by its employment in his service at the hospital of the University of Pennsylvania. Dr. Stewart said he used the expression "certain brand" because Dr. Hirst also called his attention to the great discrepancy in reports of results due to the use of different brands. This illustrated why there should be common standards for serums and bacterins. Clinical control for the guidance of dosage was more practical than the opsonic index. The amount of bacterin to be given as an initial dose was not as important as it was to learn how much to give and how frequently to repeat succeeding doses. He hoped the time would soon come when the American Therapeutic Society would work in cooperation with the American Pharmaceutical Association in fixing standards for the nomenclature, character, quality, and strength of the newer products constantly presented to the profession.

Other papers read during the meeting were: "Note on Fluorescence Excited Within Human Tissues as a Method of Treatment," by Dr. W. G. Morton, New York; "A Modified Vaccine Therapy in Pneumonia, with Animal Experiments," by Dr. P. K. Brown, San Francisco; "The Use of Nickel Sulphate in Medicine," by Dr. L. Kolipinski, Washington; "Panhysterocolpectomy: Complete Excision of the Uterus and Vagina, with Closure of Vagina, for Prolapsus," by Dr. A. E. Gallant, New York; "The Newer Heart Remedies," by Dr. W. F. Boos, Boston.

Election of Officers.—The following officers were elected: *President,* Dr. Alexander D. Blackader, Montreal; *First Vice-President,* Dr. Howard Van Rensselaer, Albany; *Second Vice-President,* Dr. Robert T. Morris, New York; *Third Vice-President,* Dr. Clarence J. Blake, Boston; *Secretary,* Dr. Noble P. Barnes, Washington; *Treasurer,* Dr. A. Ernest Gallant, New York; *Members of the Council:* Drs. Noble P. Barnes, Spencer L. Dawes, Edward D. Fisher, A. Ernest Gallant, and J. Madison Taylor; *Editor of the Transactions,* Dr. P. Brynberg Porter, New York.

Next meeting, June 6, 7, and 8, 1912, at Montreal, Canada.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

BOARD OF MEDICAL EXAMINERS OF GEORGIA.

Atlanta, May 2, 3, and 4, 1911.

ANATOMY.

1. Beneath what points on the anterior chest walls are the apex and base of the heart, and the cardiac valves?
2. What blood vessels pass to and from the liver? What arteries unite to form the basilar artery?
3. Name principal lobes of brain and fissures dividing them. What are the Meibomian glands?
4. Name twelve pairs cranial nerves. What cranial nerve has the widest distribution? Give its four principal points of distribution.
5. Name the five muscles of the shoulder. Describe briefly the quadriceps extensor femoris.
6. With what bones does the clavicle articulate? Name divisions of vertebral column, and mention marked characteristics of cervical and dorsal vertebræ.
7. Give boundaries of anterior mediastinum. Name subdivision of alimentary canal.
8. Locate and describe briefly the ilio-cecal valve. Name lobes and fissures of liver.
9. Locate the kidneys. Name arteries and veins passing to and from kidneys.
10. Describe briefly the uterus. Give divisions of the male urethra. What portion of the bladder is uncovered by peritoneum?

PHYSIOLOGY.

1. What is human physiology?
2. Mention the digestive organs.
3. (*a*) What is the difference in chyme and chyle? (*b*) What are the functions of bile, and how much is poured into the intestines in 24 hours?
4. How and where do the various types of foods, when digested, enter the body?
5. (*a*) What is systole? (*b*) diastole? (*c*) Explain how the two distinct heart sounds are produced.
6. Name the ductless glands and give the theory as to their functions.
7. What is the function of (*a*) the Eustachian tube? (*b*) the semicircular canals?
8. Describe and give the origin of the (*a*) white blood-corpuscles; (*b*) red blood-corpuscles.
9. Describe the structure of (*a*) striated muscle; (*b*) nonstriated muscle; (*c*) which is involuntary, and why?
10. (*a*) Give the physiological explanation of rapid breathing in pneumonia; (*b*) explain why pneumonia patients should be given plenty of fresh air; (*c*) what is the vital capacity of the lungs?

CHEMISTRY.

1. (*a*) What is chemistry? (*b*) What is organic chemistry? (*c*) What is inorganic chemistry?
2. What is (*a*) a molecule? (*b*) an atom? (*c*) an element? (*d*) What is synthesis? (*e*) What is valence?
3. How is (*a*) nitric acid and (*b*) hydrochloric acid made? Express the reactions in the process by giving the formulas and chemical equations.
4. What is (*a*) an acid? (*b*) a base? (*c*) salt? Give chemical formulas illustrating each.
5. Give chemical formulas for table salt, cooking soda, Epsom salts, calomel, corrosive sublimate, acetic acid, iodoform, blue vitriol, sal ammoniac, plaster of Paris. (Answer any five of these.)
6. Give chemical antidote for each of the following: carbolic acid, nitric acid, zinc salts, lead salts, iodine, caustic alkali, tartar emetic, strychnine, phosphorus, sulphuric acid. (Answer any five of these.)
7. What is a chemical antidote for arsenic? and give test for arsenic.
8. What is an alkaloid? Name one of belladonna, cinchona, pilocarpus, nux vomica, hyoscyamus, erythroxylon coca, and four of opium.
9. Name and describe test for (*a*) albumin in urine. (*b*) Sugar in urine. (*c*) Give test for indican. (*d*) In what pathological conditions is an increased elimination observed in the urine?
10. Mention a good substance used for disinfection after the prevalence of contagious diseases, and explain the chemical action in the process.

MATERIA MEDICA AND THERAPEUTICS.

1. (*a*) Name the official digestive ferments; (*b*) compare their therapeutic uses; (*c*) and tell how each is made.
2. (*a*) Give the modes of applying the hot pack; (*b*) and state the indications for its use.
3. What are the physiological effects and medicinal uses of the preparations of belladonna?
4. (*a*) Give the physiological action of ergot; (*b*) and mention its therapeutic uses.
5. Mention the medicinal uses of turpentine.

PATHOLOGY.

1. State conditions which will cause enlargement of the lymphatic glands.
2. Give pathology of erysipelas.
3. Macroscopically, state differences in throat lesion of diphtheria from that of follicular tonsillitis

4. Pathology of acute poliomyelitis.
5. Describe pathologic appearance of acute parenchymatous nephritis.
6. Name the diseases in which intestinal ulceration is an essential feature. Name the portion (or portions) of the intestinal tract in which the ulceration is found in each of these diseases.
7. Give a diagrammatic representation of a boil.
8. State difference between congestion and inflammation. Give example of each.
9. In a case of supposed abscess of appendix, what would a blood picture be worth, and how would a differential count bear to a total leucocyte count as to the prognosis of the case?
10. Name the pyogenic organisms, and differentiate each.

PRACTICE OF MEDICINE.

1. Differentiate between (*a*) chlorosis; (*b*) progressive pernicious anemia, and (*c*) leukemia; (*d*) and mention the pathological changes occurring in these diseases.
2. Distinguish between the terms (*a*) illusion; (*b*) delusion, and (*c*) hallucination as used in diagnosis.
3. Uncinariasis; (*a*) definition; (*b*) etiology; (*c*) frequency; (*d*) modes of infection; (*e*) symptoms; (*f*) skin symptoms; (*g*) diagnosis; (*h*) prognosis; (*i*) treatment to minutest details.
4. Differentiate (*a*) aortic and (*b*) mitral valvular diseases of the heart.
5. Differentiate (*a*) aortic stenosis and (*b*) aortic insufficiency.

PEDIATRICS.

1. Define (*a*) inanition, (*b*) marasmus, (*c*) malnutrition. Give etiology, symptoms, diagnosis, prognosis, and treatment of each.
2. Define pemphigus. Give its etiology, symptoms, diagnosis, prognosis, and treatment.
3. Give etiology, symptoms, diagnosis, prognosis, prophylaxis, and treatment of ophthalmia neonatorum.
4. Define cholera infantum. Give its etiology, pathology, symptoms, diagnosis, prognosis, prophylaxis, and treatment.
5. Define erythema. Give its causes, symptoms, and diagnosis. Name five drugs which frequently cause an erythema.

OBSTETRICS.

1. Give diagnosis and treatment of placenta prævia coming under your care after the beginning of labor.
2. What difficulty would you expect to encounter in occiput-posterior position and how would you overcome it?
3. Under favorable conditions of mother, would you immediately repair a lacerated perineum? Give technique of repair in superficial and in complete median lacerations.
4. What would cause recurring postpartum hemorrhage?
5. Give direction for the immediate care of the infant.

GYNECOLOGY.

1. Define caruncle of urethra and give treatment.
2. When would you use the curette? Give steps of the operation in detail.
3. Name causes of hemorrhage in a non-pregnant uterus. Give treatment.
4. State causes of leucorrhea and give treatment.
5. State immediate and remote effects of gonorrhea in the female and give treatment.
6. State the early objective and subjective symptoms of cancer of the uterus. How would you treat same?
7. What is meant by plastic operation? Describe operation for perineorrhaphy and trachelorrhaphy.
8. Give symptoms and treatment of uterine fibroids.
9. Treatment of pruritus vulvæ.
10. Give varieties of fibroid tumors of uterus.

SURGERY.

1. Name the inflammatory diseases of the bones. Define fracture; dislocation. Give differential diagnosis. Mention cardinal principles to be observed in treatment of fractures. Describe reduction of dislocation of shoulder joint by Kocher's methods.
2. What agents are employed for the production of general anesthesia, and what are the contraindications respectively of the three principal ones?
3. Describe ligation of femoral artery at Scarpa's triangle. Describe anastomosis after its ligation. What arteries are required to be ligated in amputation at middle third of leg?
4. How are wounds classified? What are the sources of wound infection? Describe briefly aseptic and antiseptic treatment of wounds.
5. Give symptoms of cholecystitis. Give symptoms of gallstones in common duct. Give treatment. Describe intussusception. Volvulus.
6. Define hernia. Name varieties of abdominal hernia. What is hydrocele? Differentiate between hydrocele and scrotal hernia. Describe briefly any one operation for the radical cure of inguinal hernia.
7. Give differential diagnosis between concussion and compression of brain. Give classification of burns. State briefly the constitutional effects and give treatment of burns.
8. What is a tumor? How are they classified? Name principal malignant tumors. Name principal varieties of mild tumors.
9. What is chancre? Chancroid? Give diagnosis of each and treatment.
10. Name varieties of fistula in ano and give treatment. Describe an operation for removal of hemorrhoids. Give symptoms and treatment of ischiorectal abscess.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

BOARD OF MEDICAL EXAMINERS OF GEORGIA.

Atlanta, May 2, 3, and 4, 1911.

ANATOMY.

1. The *apex* is in the fifth left intercostal space, about 3¼ inches from the median line. The *base* is on a line drawn from the second left interspace, about 2 inches from the median line, to the upper border of the third right intercostal cartilage, about 1¼ inches from the median line.

The *aortic valves* are behind the third intercostal space, close to the left side of the sternum. *Pulmonary valves,* in front of the aortic, behind the junction of the third rib, on the left side, with the sternum. *Tricuspid valves,* behind the middle of the sternum, about the level of the fourth costal cartilage. *Mitral valves* behind the third intercostal space, about one inch to the left of the sternum.

2. The hepatic artery and portal vein pass *to* the liver; the hepatic veins pass *from* the liver.

The two vertebral arteries unite to form the basilar artery.

3. See Cunningham's "Anatomy" (1909), page 555; or Gray's "Anatomy" (1910), page 917. The *Meibomian glands* are small sebaceous glands situated in the tarsal plates of the eyelids; they are nearer the conjunctival surface.

4. *The twelve pairs of cranial nerves* are: (1) Olfactory. (2) Optic. (3) Motor oculi. (4) Trochlear or Pathetic. (5) Trifacial. (6) Abducens. (7) Facial. (8) Auditory. (9) Glossopharyngeal. (10) Pneumogastric or Vagus. (11) Spinal Accessory. (12) Hypoglossal.

The pneumogastric has the widest distribution. *Four principal points of distribution:* Heart, lungs, stomach, and larynx.

5. Deltoid, supraspinatus, infraspinatus, teres major, teres minor. See Cunningham's "Anatomy" (1909), page 357; or Gray's "Anatomy" (1910), page 510.

6. The *clavicle articulates with:* Sternum and scapula.

The *divisions of the vertebral column* are: Cervical, dorsal, lumbar, and sacral.

The *cervical vertebræ* have a foramen in the transverse process, for the transmission of vertebral artery. The *dorsal vertebræ* have facets or demifacets for articulation with the ribs.

7. The ANTERIOR MEDIASTINUM is bounded *in front* by the sternum; *behind,* by the pericardium; *at the sides,* by the pleuræ.

Subdivisions of alimentary canal: Mouth, pharynx, esophagus, stomach, small intestine (duodenum, jejunum, and ileum), large intestine (cecum, ascending colon, hepatic flexure, transverse colon, splenic flexure, descending colon, sigmoid flexure, rectum).

8. See Cunningham's "Anatomy" (1909), pages 1077, 1114, and 1115; or Gray's "Anatomy" (1910), pages 1302, 1323, and 1324.

9. See Cunningham's "Anatomy" (1909), pages 1130 and 1140; or Gray's "Anatomy" (1910), pages 1345 and 1354.

10. See Cunningham's "Anatomy" (1909), page 1187; or Gray's "Anatomy" (1910), page 1404.

Divisions of male urethra: Prostatic, membranous, and spongy.

The under surface, lower half of posterior surface, and lower two-thirds of anterior surface of the bladder are generally uncovered by peritoneum; the fuller the bladder the more of the anterior surface uncovered.

PHYSIOLOGY.

1. *Human physiology* is that branch of science which treats of the functions of the human body in a state of health.

2. The digestive apparatus consists of: mouth, pharynx, esophagus, stomach, small intestine (duodenum, jejunum, and ileum); teeth, salivary glands, liver, and pancreas.

3. (*a*) *Chyme* is a semi-solid mass of partly digested food at the end of stomach digestion, when it is ready to be passed on into the duodenum.

Chyle is the fluid taken up by the lacteals from the intestine during digestion. (*b*) *The functions of the bile* are: (1) To assist in the emulsification and saponification of fats; (2) to aid in the absorption of fats; (3) to stimulate the cells of the intestine to increased secretory activity, and so promote peristalsis, and at the same time tend to keep the feces moist; (4) to eliminate waste products of metabolism, such as lecithin and cholesterin; (5) it has a slight action in converting starch into sugar; (6) it neutralizes the acid chyme from the stomach and thus inhibits peptic digestion; (7) it has very feeble antiseptic action. The amount of bile secreted varies from about a pint to a quart (in twenty-four hours).

4. The products of digestion find their way into the blood by two routes: (1) By the blood-vessels of the gastrointestinal tract, which unite to form the portal vein, and (2) by the lymph vessels of the small intestines, which converge to empty into the thoracic duct. The water, inorganic salts, proteids, and sugar go by way of the portal vein to the ascending vena cava; and the fats go by way of the thoracic duct to the junction of the left subclavian and internal jugular veins.

5. *Systole* is the period of contraction of the heart, chiefly of the ventricles. *Diastole* is the period of dilatation of the heart, chiefly of the ventricles.

There are two normal heart sounds which follow in quick succession, and are succeeded by a pause. The first, or systolic, sound is dull and somewhat prolonged; the second, or diastolic, sound is sharper and shorter. The *causes* producing the *first* sound of the heart are not definitely ascertained; the following are supposed to be causatory factors: (1) The vibration and closure of the auriculoventricular valves, (2) the muscular sound produced by the contraction of the ventricles, and (3) the cardiac impulse against the chest wall. The *second* sound is caused by the vibration due to the closure of the semilunar valves.

6. The *ductless* glands are: The spleen, thymus, thyroid, parathyroids, suprarenals, carotid, coccygeal, pituitary, and pineal glands.

The function of the spleen: The following theories have been held: (1) It is a source of production of the white blood corpuscles; (2) it is a source of production of the red blood corpuscles during fetal life; (3) it is a place where the red blood corpuscles are destroyed; (4) uric acid is produced in the spleen; (5) an enzyme is produced in the spleen and is carried by the blood to the pancreas, where it converts the trypsinogen into trypsin.

The function of the thyroid is not definitely settled; (1) it has some trophic function, regulating oxidation in the body, and it is supposed to have also a special influence on the vasomotor nerves, the skin, the bones, and on the sexual functions; (2) it is supposed to antagonize toxic substances, and (3) it produces an internal secretion.

The *function of the thymus* is not settled; it is said: (1) To be a blood-forming organ; (2) to have influence on growth and nutrition; (3) in hibernating animals it is supposed to store up materials which can be utilized during the period of inactivity.

The *function of the suprarenals* is not definitely settled; they produce an internal secretion which is probably necessary to life; it is supposed that they are able to destroy or remove some toxic substance produced elsewhere in the body.

The function of the *other* ductless glands is unknown. They all, or nearly all, furnish an internal secretion.

7. *The function of the Eustachian tube* is to keep the atmospheric pressure within the tympanic cavity the same as that on the outside.

The function of the semicircular canals is to aid in preserving equilibrium and in giving an idea of one's position in space; it is also believed, by some, that the semicircular canals aid in keeping the muscles of the body in a state of *tonus*.

8. The *red blood corpuscles* are biconcave discs, about 1-3200 of an inch in diameter; they are nonnucleated, and there are about 4,500,000 or 5,000,000 of them in each cubic millimeter of blood. They are elastic and soft, and their shape is changed by pressure, but is promptly regained on the removal of the pressure. Their color is yellowish. They contain hemoglobin. Their *function* is to carry oxygen from the lungs to the tissues.

In the *embryo* the red blood corpuscles are derived from cells in the vascular area of the mesoblast; in the *adult* they are derived chiefly from the red marrow of bones, also from the spleen.

The white blood cells are spheroidal masses, varying in size, having no cell wall, and containing one or more nuclei; there are about 7,000 to 10,000 of them in each cubic millimeter of blood. They differ much in appearance, and are divided into (1) small mononuclear leucocytes, or lymphocytes, (2) large mononuclear, (3) transitional, (4) polynuclear, or polymorphonuclear, or neutrophile, and (5) eosinophile. They are all more or less granular, particularly the last two varieties named. They are probably formed in the spleen, lymphatic glands, and lymphoid tissues. Their *functions* are (1) to serve as a protection to the body from the incursions of pathogenic microorganisms; (2) they take some part in the process of the coagulation of the blood; (3) they aid in the absorption of fats and peptones from the intestine, and (4) they help to maintain the proper proteid content of the blood plasma.

9. See Gray's "Anatomy" (1910), page 355.

10. The rapid breathing in pneumonia is due partly to the loss of functioning surface in the lung, partly to the fever and to the toxemia. The pneumonia patient needs fresh air to aid the aeration of the blood, to tone up the cardiovascular system, to lessen the cyanosis, and to diminish the toxemia.

The *vital capacity of the lungs* is the sum total of the complementary, tidal, and reserve air; it is about 225 to 230 cubic inches, and represents the amount of air which a person can expel from his lungs after the deepest possible inspiration.

CHEMISTRY.

1. *Chemistry* is that branch of science which treats of the composition of substances, their changes in composition, and the laws governing such changes. *Organic chemistry* is the chemistry of the carbon compounds.

Inorganic chemistry is the chemistry of substances which do not contain carbon.

2. A *molecule* is the smallest quantity of any substance which can exist in a free state.

An *atom* is the smallest quantity of an element which can enter into chemical action or that can enter into the composition of a molecule.

An *element* is a kind of substance which we cannot, by any known means, split up into any two or more dissimilar substances.

Synthesis is the process of forming compounds out of simpler compounds or elements.

Valence is the combining power of an atom of an element (or radical) as compared with that of an atom of hydrogen.

3. *Nitric acid* is made by the decomposition of potassium nitrate by sulphuric acid:

$$KNO_3 + H_2SO_4 = KHSO_4 + HNO_3.$$

Hydrochloric acid is made by the action of sulphuric acid on sodium chloride:

$$H_2SO_4 + 2NaCl = Na_2SO_4 + 2HCl.$$

4. An *acid* is a compound of an electronegative element or radical with hydrogen, part or all of which hydrogen it can part with in exchange for an electropositive element, without the formation of a base. *Examples:* H_2SO_4, sulphuric acid; HNO_3, nitric acid.

A base is a compound which on entering into double decomposition with an acid produces a salt and water. *Examples:* KOH, potassium hydroxide; NH_4OH, ammonium hydroxide.

A *salt* is a substance derived from an acid when the hydrogen of the latter has been partially or completely replaced by an electropositive element or elements (a metal or metals). *Examples:* $KHSO_4$, monopotassic sulphate; K_2SO_4, dipotassic sulphate.

5. Table salt, NaCl; cooking soda, $NaHCO_3$; Epsom salts, $MgSO_4$; calomel, Hg_2Cl_2; corrosive sublimate, $HgCl_2$; acetic acid, $CH_3.COOH$; iodoform, CHI_3; blue vitriol, $CuSO_4$; sal ammoniac, NH_4Cl; plaster of Paris, $CaSO_4$.

6. *Chemical antidote,* for *carbolic acid,* alcohol, or a soluble sulphate; *nitric acid,* magnesia, or soap; *zinc salts,* sodium or potassium carbonate, milk; *lead salts,* magnesium sulphate; *iodine,* starch; *caustic alkali,* dilute vinegar; *tartar emetic,* tannin; *strychnine,* tannic acid; *phosphorus,* old French oil of turpentine; *sulphuric acid,* magnesia.

7. The *chemical antidote for arsenic poisoning* is freshly prepared ferric hydroxide. The ferric hydroxide changes the arsenic into ferrous arsenate, which is non-poisonous.

Test for arsenic: Reinsch's test is as follows: To the suspected fluid add a little pure HCl; suspend in the fluid a small strip of bright copper foil, and boil. If a deposit forms on the copper, remove the copper, wash it with pure water, dry on filter paper, but be careful not to rub off the deposit. Coil up the copper, and put it into a clean dry glass tube, open at both ends, apply heat at the part where the copper is. If arsenic is present there will appear in the cold part of the tube a mirror, which will be found on microscopical examination to consist of octahedral crystals of arsenic trioxide.

8. An *alkaloid* is a basic nitrogenous substance capable of combining with acids to produce salts in the same way that ammonia does. *Belladonna,* atropine; *cinchona,* quinine; *pilocarpus,* pilocarpine; *nux vomica,* strychnine; *hyoscyamus,* hyoscyamine, *erythroxylon coca,* coacaine; *opium,* morphine, codeine, narcotine, and papaverine.

9. *Test for albumin*: "The urine must be perfectly clear. If not so, it is to be filtered, and, if this does not render it transparent, it is to be treated with a few drops of magnesia mixture, and again filtered.

"The reaction is then observed. If it be acid, the urine is simply heated to near the boiling point. If the urine be neutral or alkaline, it is rendered *faintly* acid by the addition of dilute acetic acid, and heated. If albumin be present, a coagulum is formed, varying in quantity from a faint cloudiness to entire solidification, according to the quantity of albumin present. The coagulum is not redissolved upon the addition of nitric acid."

Test for sugar: First remove any albumin that may be present, then "render the liquid strongly alkaline by addition of sodium carbonate. Divide about 6 c.c of the alkaline liquid in two test-tubes. To one test-tube add a very minute quantity of powdered subnitrate of bismuth, to the other as much powdered litharge. Boil the contents of both tubes. The presence of glucose is indicated by a dark or black color of the bismuth powder, the litharge retaining its natural color."

Test for indican in the urine: The urine is mixed with one-fifth its volume of 20 per cent. solution of lead acetate and filtered. The filtrate is mixed with an equal volume of fuming hydrochloric acid containing 3:1,000 of ferric chloride, a few drops of chloroform are added, and the mixture strongly shaken one to two minutes. With normal urine the chloroform remains colorless, or almost so; but if an excess of indoxyl compounds be present the chloroform is colored blue, and the depth of the color is a rough indication of the degree of the excess. (From Witthaus' *Essentials of Chemistry.*)

There is an increased elimination of urine: In diabetes, chorea, hysteria, epilepsy, granular atrophy of the kidneys; after the ingestion of much fluid, and during the absorption of large effusions.

10. Sulphur dioxide, SO_2 is a good disinfectant where penetration is not required. The presence of moisture is necessary, when $H_2O + SO_2 = H_2SO_3$. This sulphurous acid is really the disinfecting agent.

MATERIA MEDICA AND THEREPEUTICS.

1. (*a*) Pepsin and pancreatin. (*b*) Pepsin is only of use in an acid medium, as in an alkaline medium it is decomposed; pancreatin acts in an alkaline medium. Pancreatin is preferred for the predigestion of albuminous foods; and pancreatin alone will digest other kinds of foods. Hence pancreatin is of more use than pepsin. (*c*) Pepsin is made from the glandular layer of the fresh stomach of the hog; pancreatin is made from the fresh pancreas of the hog.

2. *Hot pack.* "A bed is prepared by covering it with a rubber blanket. Over this is placed a dry woolen blanket. A large, heavy blanket is now dipped in very hot water and then wrung out, and the naked patient quickly wrapped in it, the dry blanket being folded over him after several hot-water bottles have been placed alongside the patient. Finally the sides of the rubber sheet are drawn around and over the patient and an ice-cap placed on the head. A thermometer should be placed in the mouth every half hour, and if the patient's temperature becomes febrile (101°) he should be taken out of the blankets and rubbed dry."—(From Hare's *Practical Therapeutics.*)

The hot pack is used, not only to cause sweating and so relieve the patient of poisons and fluid in renal diseases, but also to relax muscle spasm and to relieve nervous excitement and nervous insomnia. It is particularly efficacious in the nervous insomnia of severe chorea in children.

3. Belladonna and Its Preparation. *Physiological effects:* Anodyne, mydriatic, inhibits secretions, depressant of terminations of nerves, accelerates the heart beat, causes rise in blood-pressure, but toxic doses cause the blood-pressure to fall, stimulates the respiratory center, but large doses depress the same; it may cause vertigo, restlessness, excitement, delirium, or mania.

Medicinal uses: To relieve pain, relax spasm, check sweating, as a mydriatic, for night sweats, to check griping of purgatives; in asthma, to check fevers, in heart disease, shock and collapse, acute coryza, urinary incontinence, chordee, low delirium of fevers, mania, alcoholism; as an antigalactagogue, and for spasmodic cough.

4. Ergot. *Physiological action:* Ergot stimulates and causes contraction of involuntary muscle fibers, hence it is a vasoconstrictor, hemostatic, and oxytocic. It is also a cardiac sedative, it raises the blood-pressure, it increases peristalsis, and is an emmenagogue. *Principal therapeutic uses:* To promote uterine contractions during third stage of labor; fibroids, menorrhagia, postpartum hemorrhage. Some forms of amenorrhea and dysmenorrhea, dysentery, arterial hemorrhage, congestive headaches, laxity of sphincters, of bladder or rectum, hemorrhoids, aneurysm, diabetes, urinary incontinence, direct paralysis of the sphincter vesicæ, atonic spermatorrhea.

5. *Turpentine* is used as a rubefacient or counterirritant; in sciatica, lumbago, neuralgia, chronic rheumatism, sprains, dysentery, hemorrhage of intestines; as a vermifuge against tapeworm; chronic bronchial affections and chronic affections of the genitourinary tract.

PATHOLOGY.

1. *The lymphatic glands are enlarged* in: Hodgkin's disease, lymphatic leukemia, filariasis, syphilis, malignant disease, tuberculosis, gonorrhea, adenitis, and sometimes in some of the acute infectious diseases.

2. See French's "Practice of Medicine" (1910), page 218.

3. See French's "Practice of Medicine" (1910), pages 183, 187, and 735; or Osler's "Practice of Medicine" (1909), pages 198 and 446.

4. See French's "Practice of Medicine" (1910), page 1068; or Osler's "Practice of Medicine" (1909), page 915.

5. See French's "Practice of Medicine" (1910), page 911; or Osler's "Practice of Medicine" (1909), page 687.

6. *Intestinal ulceration* is an essential feature in: (1) *Typhoid fever,* in which it occurs chiefly in Peyer's patches, and opposite the mesenteric attachment; (2) *Tuberculosis of intestine,* in which it may occur in any part of the intestine; (3) *Peptic ulcer of the duodenum;* (4) *Burns,* chiefly found in duodenum; (5) *Syphilis of intestine,* in Peyer's patches, and lower part of intestine and rectum; (6) *Dysentery,* generally large intestine (cecum, rectum, and hepatic and sigmoid flexures).

7. See Rose and Carless' "Surgery" (1908), page 398; or Da Costa's "Surgery" (1908), page 1056.

8. See Da Costa's "Surgery" (1908), page 73.

9. In *appendicitis:* The mildest and the severest cases show no leucocytosis. The total absence of leucocytosis in a case not obviously mild is a very bad prognostic sign. An increasing leucocytosis means a spreading process, and may be the only evidence of the fact. A steadily increasing leucocytosis is always a bad sign; it is of far more significance than a larger count which does not increase.—(Cabot.)

10. See Rose and Carless' "Surgery" (1908), page 57; or Da Costa's "Surgery" (1908), page 42.

PRACTICE OF MEDICINE.

1. See French's "Practice of Medicine" (1910), pages 523, 520, 529, and 531; or Osler's "Practice of Medicine" (1909), pages 722, 726, and 733.

2. A *delusion* is a belief in something which has no real existence, but is purely imaginary; and out of which the person cannot be reasoned. An *illusion* is a false or perverted impression, received through one of the senses. An *hallucination* is the same as an illusion, but without any material basis.

If an individual believes himself to be made of glass, and is afraid of being touched lest he be broken, he is suffering from a *delusion.* If the whistling of the wind is mistaken for a voice telling a person to do a certain thing—that would be an *illusion.* If a person fancied he heard a voice when there was nothing at all to be heard, that would be an *hallucination.*

3. See French's "Practice of Medicine" (1910), page 505; or Osler's "Practice of Medicine" (1909), page 404.

4.

AORTIC DISEASE.	MITRAL DISEASE.
Symptoms are mainly due to anemia, viz.:	Symptoms are mainly due to venous congestion, viz.:
1. Pallor.	1. Cyanosis.
2. Throbbing of the carotids.	2. May get pulsation in the veins of the neck.
3. Attacks of an "angina pectoris" type of pain.	3. Sudden attacks of severe dyspnea—actual acute pain is rare.

AORTIC DISEASE.	MITRAL DISEASE.
4. Breathlessness on slight exertion.	4. Breathlessness, but often present without exertion.
5. Nervous symptoms are prominent, owing to cerebral anemia. Syncopal attacks are also common.	5. Pulmonary symptoms are most prominent, *i.e.* cough in the morning, chronic bronchitis, hemoptysis, dilated right side of heart, and later symptoms due to tricuspid leakage.
6. The *left ventricle* is usually much hypertrophied.	6. The *left auricle* is somewhat hypertrophied, but the main hypertrophy is that of the *right ventricle*.

—(From Wheeler and Jack's *Handbook*.)

5. See French's "Practice of Medicine" (1910), pages 603 and 599; or Osler's "Practice of Medicine" (1909), pages 803 and 799.

PEDIATRICS.

1. *Inanition* is exhaustion from lack of food or from food that has not been assimilated. *Marasmus* is extreme emaciation or atrophy, not due to any specific or obvious cause. *Malnutrition* is faulty nutrition due to non-assimilation of food.

INANITION may be *due* to the child refusing food, or only taking a very small amount; inadequate or improper food; feeble powers of digestion. *Symptoms:* Loss of weight, temperature high or subnormal, pulse weak and rapid, urine scanty and diminished chlorides; cold extremities, muscular relaxation, pallor, cyanosis, collapse. *Prognosis* uncertain. *Diagnosis:* It is distinguished from malnutrition by its greater severity, and from marasmus by its more acute character. It may be mistaken for indigestion meningitis, gastroenteritis. *Treatment:* Procure a wet nurse if necessary, breast milk should be diluted and given with a spoon or medicine dropper, whey mixtures or rectal feeding may be tried, rectal injections of salt solution, spraying or tepid baths, and stimulants are all indicated.

MALNUTRITION may be hereditary, due to syphilis or tuberculosis, or alcoholism or gout, prematurity or improper feeding. *Symptoms:* Weight is subnormal, development poor, the head is relatively large, mentally the child may be bright, indigestion is common, anemia may be present. *Diagnosis:* Must distinguish between tuberculosis, syphilis, rickets, malaria, blood diseases, organic conditions; the etiology must be studied. *Prognosis* depends on the cause and the possibility of its removal. *Treatment* is mainly dietetic and general, drugs are of small service. Food must be according to the child's digestive capacity. Regular hours, freedom from excitement, open-air exercise, limited mental work, tonics, cold spraying, etc.

MARASMUS may be congenital, due to poverty or artificial feeding, overcrowding. *Symptoms:* Loss of weight, an old look, wrinkled skin, legs like drum sticks, prominent abdomen, hollow temples, shrunken fontanels, large eyes, sharp features, anemia, hemic murmur, edema, vomiting, loss of appetite. *Diagnosis* depends on symptoms, but it may be difficult to differentiate it from malnutrition. *Prognosis* depends on age of infant and extent of disease. *Treatment* consists in proper feeding and fresh air; good cow's milk or wet nurse's. No drugs are required.—(From Holt.)

2. PEMPHIGUS is an eruption of bullæ on a red base with serous contents. It may be due to traumatism, or syphilis, or infection. There is a bullous eruption on abdomen, neck, face, or thighs; generally first seen on trunk; the bullæ may rupture in one or two days and a crust forms, which latter falls off, leaving a red or violet patch on the skin. The important point in the diagnosis is to distinguish between the syphilitic and non-syphilitic variety. *Prognosis* is variable; good when there are but few bullæ, serious when many are present. *Treatment* consists in cleanliness, antiseptic powders or lotions, or a 1 per cent. solution of ichthyol.

3. OPHTHALMIA NEONATORUM. *Causes:* The gonococcus or some other pyogenic microorganism; the secretions of the mother contain the infecting agent, and transmission may occur directly during parturition, or indirectly by the fingers of physician or nurse, cloths, instruments, etc. *Symptoms:* Swollen eyelids, with copious purulent discharge; ulceration of the cornea may ensue. *Prophylaxis:* Whenever there is the possibility of infection, or in every case, wash the eyelids of the newborn child with clean warm water, and drop on the cornea of each eye one drop of a 1 per cent. solution of nitrate of silver, immediately after birth. *Treatment:* Wash the eyes carefully every half hour with a saturated solution of boric acid; pus must not be allowed to accumulate. Two drops of a 2 per cent. solution of nitrate of silver must also be dropped on to the cornea every night and morning. The eyes must be covered with a light, cold, wet compress. The patient must be isolated, and all cloths and compresses used must be burnt.

4. See French's "Practice of Medicine" (1910), page 800; or Osler's "Practice of Medicine" (1909), page 507.

5. *"Erythema simplex* is a circulatory disturbance of the integument characterized by variously sized and shaped areas of redness unattended by elevation or depression. It is accompanied by mild itching or burning, and disappears on pressure. It may be due to exposure to extremes of temperature, exposure to the sun's rays, injury, irritation of poisonous plants, or to the absorption of drugs, antitoxins, ptomaines, etc.

"Erythema intertrigo or chafing is the variety of hyperemia encountered in regions such as the buttocks, genital regions, and flexures of joints, in which the skin surfaces are in apposition and rub one on the other. In the obese and in infants it is very frequent and often develops into a true dermal inflammation. Redness, heat, and burning are symptoms; and sometimes there may be a mucoid discharge."—(Hughes' *Practice of Medicine*.)

Five drugs which may cause erythema: Belladonna, quinine, morphine, salicylic acid, chrysarobin.

OBSTETRICS.

1. See Williams' "Obstetrics" (1909), pages 814 and 816; or Hirst's "Obstetrics" (1909), page 577.
2. See Williams' "Obstetrics" (1909), page 266; or Hirst's "Obstetrics" (1909), pages 404 and 407.
3. See Williams' "Obstetrics" (1909), page 325; or Hirst's "Obstetrics" (1909), pages 609 and 867.
4. See Williams' "Obstetrics" (1909), page 818; or Hirst's "Obstetrics" (1909), pages 585 and 586.
5. See Williams' "Obstetrics" (1909), page 346; or Hirst's "Obstetrics" (1909), pages 344 and 373.

GYNECOLOGY.

1. *Urethral caruncle* is a small red fleshy growth generally situated on the posterior part of the meatus of the urethra. There are local pain and tenderness, which may be excessive; a burning sensation is experienced on urination; it may bleed. The proper treatment is to excise it or destroy it with the thermocautery.

2. CURETTAGE. *Indications:* For diagnosis, to remove pieces of retained placenta or decidua, endometritis, mucous polypi, hemorrhage, dysmenorrhea, endocervicitis. *Dangers:* Sepsis, perforation of uterus, hemorrhage, abortion, inflammation of uterus or adnexa. *Procedure:* All antiseptic and aseptic precautions are necessary, the patient should be in the dorsal position, the vagina is to be disinfected, and the cervical canal dilated; a speculum is introduced into the vagina and the cervix is drawn down with volsella; the uterine cavity is irrigated with creolin or lysol; a curette is inserted to the fundus and moved down to the internal os; the operator should begin at one cornu, and go in the same direction all around till he reaches the starting point, and if necessary repeat till no more spongy or hyperplastic tissue appears; the fundus should be scraped separately by moving the curette along it from side to side; in going towards the fundus no scraping should be done, and care must be taken not to perforate the uterus; should this happen no fluid must be injected; otherwise the uterus and vagina are again irrigated, and one or more strips of iodoform gauze are inserted into the cavity to act either as a hemostatic plug or as a drain, which is diminished with two days' interval and withdrawn on the sixth day. A hemostatic tampon should be placed in the vagina and withdrawn the following day. If any fever arises the tampon is at once removed and the vagina douched with antiseptic fluid every three hours. If not, the vagina is only swabbed with the same every day, and packed loosely with iodoform gauze. After the final removal of the gauze the antiseptic douche is given twice a day until there is no more discharge. The patient should remain in bed for a week.

3. *Hemorrhages occurring in the non-pregnant woman:*

A. In virgins before the age of thirty: Caused by (1) uterine congestion, the result of cold or exposure; (2) endometritis; (3) polypi and fibroid tumors.

B. In married women before the age of thirty: Caused by (1) subinvolution; (2) laceration of the cervix; (3) endometritis; (4) retrodisplacements of the uterus; (5) polypi and fibroid tumors.

C. In women after the age of thirty: Caused by (1)

carcinoma of the cervix; (2) carcinoma of the body of the uterus; (3) sarcoma of the uterus.

4. *Leucorrhea may be produced by:* Pelvic congestion, endometritis, retroversion of uterus, vulvitis, vaginitis, gonorrhea, benign and malignant growths.

Treatment consists in removal of cause, rest, vaginal douches (cleansing, or astringent, or antiseptic, according to the cause).

5. Gonorrhea. *Symptoms:* Pain and burning in the vulva; pain and burning on micturition; dyspareunia; yellowish or greenish discharge, in which the gonococcus can be found; the vagina is hot, red, swollen, and tender. *Possible results:* Cystitis, urethritis, vulvitis, endometritis, salpingitis, septic peritonitis, sterility, condylomata of vulva, abscess of Bartholin's glands.

Treatment: Rest, if possible in bed; freedom from alcoholic or sexual excitement; a mild and unirritating diet; salines and diuretics; plenty of water to drink; a warm sitz bath; douching of vagina with about a gallon of a 1:5000 bichloride solution, or of borax (1 dram to the quart); the douche is to be taken in the recumbent position.

6. See Rose and Carless' "Surgery" (1908), page 1286.

7. *Plastic operations in gynecology* are such as are done: (1) for the repair of lacerations of the perineum or cervix; (2) for vaginal fistulæ; (3) for the narrowing of the vagina, and the treatment of cystocele or rectocele; and (4) various other operations on vulva, urethra, or anus.

For *perincorrhaphy*, see Obstetrics, Question 3.

For *trachelorrhaphy*, see Hirst's "Obstetrics" (1909), page 857.

8 and 10. See Rose and Carless' "Surgery" (1908), page 1280.

9. *Treatment of pruritus vulvæ* consists in removing the cause, if possible; cleanliness, fresh air, tonics, and general attention to hygiene; local applications of solution of bichloride of mercury, 1:2000; or carbolic acid, 1:100; or lead and opium; dusting powders of bismuth subnitrate, calomel, or zinc oxide are also useful.

SURGERY.

1. See Rose and Carless' "Surgery" (1908), pages 567, 464, 609, 475, and 622; or Da Costa's "Surgery" (1908), pages 431, 440, 446, 579, 460, and 590.

FRACTURE.	DISLOCATION.
1. Crepitus may be present.	1. Crepitus never present.
2. Preternatural mobility.	2. Rigidity rather than mobility.
3. Easily reduced—but	3. Difficult to reduce—but
4. Deformity more liable to recur after reduction.	4. Deformity less liable to recur after reduction.
5. The head of the bone is in its proper place.	5. The head of the bone is not in its proper place.
6. The socket containing the head of the bone is not empty.	6. The socket which should contain the head of the bone is empty.
7. When rotated the bone does not move as one piece.	7. When rotated the bone moves as one piece.

2. See Rose and Carless' "Surgery" (1908), pages 1321 and 1326; or Da Costa's "Surgery" (1908), page 1025.

3. See Rose and Carless' "Surgery" (1908), page 340; or Da Costa's "Surgery" (1908), page 423.

Anastomosis after ligation of femoral artery at apex of Scarpa's triangle: (1) External circumflex; with muscular branches of femoral, anastomotica magna, superior articular of popliteal, and anterior tibial recurrent. (2) Perforating and terminal of profunda; with muscular branches of femoral, and muscular and superior articular branches of popliteal. (3) Comes nervi ischiadici; with perforating of profunda and articular of popliteal.

In amputation at middle third of leg, the anterior tibial, posterior tibial, and peroneal arteries require to be ligated.

4. *Wounds are classified* as:

I. Contused and open wounds.

II. Open wounds may be: Incised, lacerated, contused, punctured, gunshot, or poisoned; also penetrating and perforating.

III. Aseptic and septic.

Sources of wound infection: Air; water; patient's skin, hair, or clothing; hands of surgeon, assistants, or friends; instruments and dressings; solutions; insects.

See Rose and Carless' "Surgery" (1908), pages 264 and 266; or Da Costa's "Surgery" (1908), page 51.

5. See Rose and Carless' "Surgery" (1908, pages 1059, 1060, 1061, 1119, and 1113; or Da Costa's "Surgery" (1908), pages 883, 885, 891, 894, and 837.

6. See Rose and Carless' "Surgery" (1908), pages 1068, 1265, 1072, and 1081; or Da Costa's "Surgery" (1908), pages 971, 1201, 1000, and 978.

7.

CONCUSSION OF THE BRAIN.	COMPRESSION OF THE BRAIN.
Unconsciousness is incomplete; patient can be made to answer, though it may be briefly and in simple words.	Complete unconsciousness; may scream into patient's ear at the top of the voice, but will receive no answer.
Special senses, though greatly blunted, are not abolished.	Special senses entirely suspended.
Power of movement not destroyed; if the position of a limb be changed the patient will resist or bring it immediately into the original position.	Complete or partial paralysis; in most cases hemiplegia.
Respiration is quiet and feeble.	Respiration full and noisy.
Pulse feeble, frequent, and intermittent.	Pulse full and slow, and sometimes laboring.
The stomach sickens and rejects its contents.	The stomach is insensible to any impression; no nausea or vomiting.
The feces may be discharged incontinently, as may also the urine, though not usually.	Bowels are torpid, and the bladder incapable of emptying itself, though the urine may escape by overflow.
Deglutition little impaired.	Deglutition difficult or impossible.
Pupils variable, though generally contracted; the eyelids somewhat open.	Pupils variable, though generally much dilated, and the eyelids closed.
Temperature of the body less than natural.	Temperature almost natural, a little below the normal standard.

—(From Treves' *Manual of Surgery.*)

See Rose and Carless' "Surgery" (1908), pages 115, 116, and 117; or Da Costa's "Surgery" (1908), pages 1052 and 1053.

8. A *tumor* is a pathological new growth which tends to persist independently of the structures in which it lies, and which performs no physiological function.

Tumors are classified as follows:

I. Those derived from mesoblast:
  (*a*) *Benign:* Lipoma, fibroma, chondroma, osteoma, myxoma, myoma, neuroma, glioma, angioma, lymphangioma.
  (*b*) *Malignant:* Sarcoma.

II. Those derived from epiblast or hypoblast:
  (*a*) *Benign:* Adenoma, papilloma.
  (*b*) *Malignant:* Carcinoma.

III. Cystic tumors.

IV. Teratomata.

9. See Rose and Carless' "Surgery" (1908), pages 140, 144, 141, and 157; or Da Costa's "Surgery" (1908), pages 276, 277, 288, and 1179.

CHANCRE.	CHANCROID
First lesion of a constitutional disease, viz., syphilis.	A local disease.
Due to syphilitic infection.	Due to contact with secretion from chancroid.
Generally a venereal infection.	Always a venereal infection.
May occur anywhere on the body.	Nearly always on genitals.
Period of incubation never so short as ten days.	Period of incubation always less than ten days (generally about three).
Generally single.	Generally multiple.
Not autoinoculable.	Autoinoculable.
Secretion slight.	Secretion profuse and purulent.
Slightly or not at all painful.	Generally painful.
As a rule only occurs once in any patient.	May reoccur in same patient.
Buboes are painless and seldom suppurate.	Buboes are painful and usually suppurate.

10. See Rose and Carless' "Surgery" (1908), pages 1134, 1136, 1152, and 1132; or Da Costa's "Surgery" (1908), pages 1009, 1010, and 1015.

CONSTANT OCCURRENCE OF MIXED INFECTIONS.

BY W. HANNA THOMSON, M.D., LL.D.,

NEW YORK.

IN the management of any infections disease the aim of the practical physician should be to prevent the infection from becoming multiple. If he succeeds in keeping it single, even the worst of them, like tuberculosis, may develop into a comparatively mild affection. Thus as the tubercle bacillus has no liking for fresh air and is killed in a few minutes by sunlight, it finds that in the peritoneum it is quite safe from both air and light and may give rise there to an extensive tuberculous inflammation. Meanwhile, however, in these dark recesses it is quite lonely and without help from its common powerful allies. The surgeon, therefore, on opening the abdominal cavity finds the peritoneum studded with tubercles, but, on sewing the wound up, both the peritonitis and the tubercles forthwith disappear, to the wonderment and gratification of the operator. The explanation is that the exposure during the operation to air and light so weakened the tubercle bacillus that nature's great resource, viz., the vital resistance of the tissues, put an end to this debilitated enemy's further proceedings. It is only when it can call in the aid of other organisms that tuberculosis becomes the scourge of the human race.

Hence the importance of remembering that there are two factors always present in every infection. The first is the invading microorganism itself, and the other is the opposing resistance of the tissues and fluids of the body invaded. The issue will then depend on which of those two forces is the best equipped for the contest. We will soon show how the most dangerous multiple invasions may be safely left to the vital powers of the system, provided that they are properly helped by the physician and that not by medicine.

These principles are particularly well illustrated in smallpox, for in this disease we may have three wholly separate infections. The first is the attack of smallpox itself, whose causative agent has not yet been identified. Its onset is quite characteristic, beginning with vomiting, severe headache, aching of the back and limbs, and high fever. But by the fifth day everything subsides, the temperature falls, the tongue cleans, the stomach is no longer irritable and the appetite returns. Sleep now becomes possible and the patient feels as if he were getting well. Meantime, however, the eruption appears, at first as a solid pimple, tipped with its specific vesicle. But soon a wholly different infection follows, which is virtually a surgical disease. On account of the myriads of cocci swarming over it, no surgeon will make the smallest incision through the skin until he has washed and scrubbed the part with disinfecting lotions, and then he will wash his own hands and clean his finger nails, or, still better, wear thoroughly disinfected gloves, before he once touches the knife.

Now the pustular eruption of smallpox does exactly what the surgeon aims to prevent with his aseptic procedures. Every vesicle becomes invaded, usually with the *Staphyloccus pyogenes aureus*. The original variola agent is there still, with increased vigor from its new allies, but the case has now become one of true surgical pyemia. Every pustule lends its contingent of pyogenic cocci to cause a new fever along with the ulcerations, which so disfigure the features beyond recognition, ultimately leaving behind life-long scars.

There must, however, be some specific influence operating in this papular eruption, because extensive eruptions of pimples occur in other affections without becoming so purulent as they do in smallpox. That specific agent is in the original clear vesicle of the variolous eruption. If the patient has not been vaccinated before, and thus the original virulence not lessened, we have the spectacle of confluent smallpox, instead of the discrete varioloid. Therefore, to call a noisy opponent of vaccination an ass is not quite fair to that quarduped, who does show some intelligence compared with his biped rival, while he brays so loudly against the safest and most effectively preventive inoculation in the world.

Years ago, at the New York Quarantine, I was physician to a large smallpox hospital. I then turned all the patients into the likeness of Congo negroes by painting face and hands with a saturated solution of nitrate of silver. It worked admirably, for when they got well and shed their skin, they were not only no longer Ethiopians, but their faces afterward showed no scars. I did not known then what staphylococci or streptococci were, nor why this procedure seemed to be so generally beneficial. But it occurs to me now to ask whether we could not prevent this secondary infection in smallpox, which of itself so often kills, by frequently washing the skin on the first appearance of the pimples with Lawrence Smith's solution of bromine, a solution which is not locally irritating, but which no coccus of any form can stand.

There remains the third and most malignant secondary invasion, that of hemorrhagic smallpox. This invasion occurs very early, usually before the specific eruption appears, so that I have known the best trained physicians to be caught napping by this terrible enemy. That it is due to a secondary invasion is proved by an examination of the blood, which reveals a general and intense *streptococcemia*. Now, smallpox itself is not caused by a streptococcus, for then it would long ago have been so identified. How this streptococcus makes its fatal entry we do not know, but it teaches us the important lesson that the original infecting agent may have

its virulence indefinitely heightened by alliance with another microbe, for many deaths have followed unwitting attendance on the funeral of hemorrhagic smallpox victims.

These principles, however, have their most striking illustrations in scarlet fever and in diphtheria. On that account, I cannot refrain from quoting some passages from a paper read before the American Association of Physicians, Washington, and reported in the MEDICAL RECORD, August 28, 1909. The title of the paper was "A Severe Case of Scarlatina and of Diphtheria Successfully Treated Without Medicines." The case, in brief, was this. A little girl, aged five, was suddenly taken with scarlatina in the night. The throat was severely affected and the characteristic rash ran its usual course, with a temperature of 104.2°. Three days after the rash appeared a diphtheritic exudation developed in the throat and extended with great rapidity, in spite of the injection of 15,000 units of antitoxin. I was then called in consultation by the attending physician, Dr. George B. Ferguson, of the Bronx Borough of New York, on the sixth day of the scarlatina and the third day of the diphtheria. The appearance of the throat was then bad enough, the diphtheritic exudation covering the uvula, both palatal arches, the tonsils, and the pharynx so that all these parts were practically hidden by the overlying membrane. The child was wholly unable to swallow, the glands on both sides of the neck were swollen, and the breath had a gangrenous odor. What concerned me most, however, was the unfavorable aspect of the countenance. The child was apathetic and presented a picture of serious septic infection. The pulse was weak and thready. I told the doctor that it was useless to think of administering medicine, first, because the child was wholly unable to swallow, and, secondly, because we had no medicinal remedies for any of the exanthemata, while it was plain that the diphtheria antitoxin would no longer avail in this case. Meanwhile, the hypodermics of strychnine given for her cardiac and general prostration would be no more effective than emptying the little syringe into the grate fire. The only recourse, therefore, was to deal with her throat as we would wash a dirty sidewalk with a hose. I recommended, therefore, that two gallons of hot water, with two teasponfuls of chlorate of potassium and five drops of oil of peppermint dissolved in it, be made to pour in her throat every two hours, day and night, from a fountain syringe bag elevated six feet above her head. To prevent her gagging or swallowing of the water, her mouth was to be kept wide open by a rubber plug held between the teeth.

For the first few days the patient felt such relief from this douching that she offered no resistance. Great quantities of the exudates came away with the return current. On my second visit, two days afterwards, though the patient was still unable to swallow, I was gratified to note a marked change in her expression, and the enlarged cervical glands looked smaller. On my third visit, two days after that, she could swallow, though extensive diphtheritic patches still remained. I then told the doctor that now we were as if in a canoe shooting a rapid with these rocks ahead. First, abscesses in the ears from the scarlatina; secondly, pneumonia, which, in my experience, carries off 20 per cent. of the fatal cases of scarlatina; thirdly, pleurisy, with a special tendency to empyema; fourthly, cardiac paralysis from the toxin of diphtheria, and lastly, scarlatinal nephritis. All of these occurred in their order, except the last, the kidneys never showing the least disturbance. The very next morning after my third visit, Dr. Samuel Goldstein, the aurist, found abscesses in both ears, which, on puncturing the drum, discharged profusely, and continued to do so for over a week, but by his assiduous and skillful management the ears recovered perfectly. On the eighth day of her illness, the temperature, which had fallen to 102°, rose to 105°, and with it there was a marked rise in the leucocyte count. I then found a patch of pneumonic consolidation in the left midscapular region, which was farther surrounded by an area of pleuritic râles extending to the base of the lung posteriorly. Nothing was prescribed for this complication except to continue the throat douching. In five to seven days both the pneumonic signs and the friction râles disappeared; the throat was clear of all diphtheritic patches, the cervical glands had become normal, and the patient was very hungry. But the pulse now became very weak and intermittent, and then, for the first time, on the twenty-fifth day of her illness, she took medicines in the form of cardiac stimulants in a pill of powdered squills, caffeine, and strychnine. I may add that I was careful not to administer digitalis, because I have seen very painful results from giving digitalis in diphtheritic weakening of the heart, not only because digitalis then fails to increase the power of the heart's systole, but because the arteries at such times seem to become especially sensitive to the arterial contraction, which is one of the effects of this drug. However, the recovery of the heart was very slow, and it continued to be weak and intermittent for six weeks. The child continued to show for some time weakness of the legs and a muffled, nasal voice from paralysis of the palate, but ultimately recovered and is now the picture of health.

The history of this case seems to me to support the view that the characteristic complications of scarlatina arise not so much from the original infection as from the invasion of virulent streptococci through the portal opened for them by the local angina in the throat. From them it is that the successive series of tissue changes and inflammations develop. In other words, the exanthem first inflames the throat, and the streptococci then do the rest. In this sense scarlatina becomes as local a source of toxemia as diphtheria itself is. With diphtheria also, when ulcerated surfaces are present, mixed infections occur which may wholly neutralize the action of its specific antitoxin.

Our case, therefore, emphasizes these practical lessons: 1. The diphtheritic exudation is altogether a local affair, for its bacillus rarely enters the blood. All its serious or lethal effects are due to its absorbed toxins. By washing away the exudation so thoroughly we diminish by so much the quantity of toxins which the system had to neutralize. The same result was secured with the infections due to the scarlatina, only that here the washing prevented the entrance of myriads of streptococci from the ulcerated sore throat. Whatever causes such ulcerations opens the way for this mixed streptococcal infection, and hence this occurs also in the throat ulcerations of diphtheria, often sufficiently to neutralize the effects of its specific antitoxin. It is my custom now to order thorough throat douching in every case of scarlatina from the earliest beginning of the sore throat, and I am sure that nearly every complication of this disease could be thus prevented.

The conclusion, therefore, seems legitimate that though otitis, pneumonia, and pleurisy were not prevented in this case, yet they each ran a much milder course because the patient's powers of vital resistance did not have so much with which to contend as they otherwise would. Moreover, it is a familiar clinical fact that virulence is directly proportional to the size of the dose of the invading microorganism, for when few they are scarcely able to do harm.

Mixed infections are the rule in inflammatory affections of the respiratory passages in children. Dr. L. Emmet Holt proves this in a published report of his examinations in which the post-mortem findings corresponded with the clinical findings by sputum cultures. Thus the growth from the lungs of 76 pneumonia cases showed: *B. influenzæ* alone, 2; pneumococcus alone, 4; streptococcus alone, 1; *Staphylococcus aureus* alone, 8; *B. influenzæ* and pneumococcus, 5; *B. influenzæ* and streptococcus, 5; *B. influenzæ* and staphylococcus, 7; pneumococcus and streptococcus, 1; pneumococcus and staphylococcus, 11; pneumococcus and catarrhalis, 5; staphylococcus and streptococcus, 10.*

Such a hopeless list of mixed infections emphasizes the importance of immediately dealing with the bronchitis of children. But when once under way it would seem as if no recourse remains but to try vaccines of polyvalent serums.

Our quotation from Dr. L. Emmet Holt about the host of mixed infections which occur in the bronchopneumonia of children prepares us now to understand what the special dangers of pulmonary phthisis are.

We begin with bronchitis. Our text books all share the same defect that while they give every particular about auscultation, they wholly omit a subject of much practical importance, namely, how to recognize the significance of the sound of a cough. There are two sorts of coughs which can be distinguished at once from each other by their sound; first, the expectorant cough, and, second, a cough which has nothing to do with expectoration. Of the first, or the expectorant cough, there is only one kind; of the non-expectorant there are fourteen kinds. The practical point is that the expectorant cough always should be promoted, while every one of the non-expectorant coughs should be suppressed if possible, for it can only do harm. A little practice is all that is needed to tell one kind from the other simply by its sound. The expectorant cough is like a chain running over a pulley, *i. e.* each cough is linked to that which precedes it and to that which follows, nor can it be stopped until it ends in expectoration. In the non-expectorant coughs the sounds, however numerous or loud, are independent of each other, like the blows of a hammer. Thus I was called by two physicians to see a man who had not been able to sleep for more than a week, owing to a violent cough which kept up day and night, notwithstanding opiates and other sedatives. When I heard the cough I knew that he had nothing in his bronchial tubes to expectorate, and soon found that he had had an extensive pleuritic effusion which had been absorbed, leaving the pleural surfaces covered with plastic layers to rub against each other with loud creaking or auscultation. I ordered the whole chest on that side to be firmly strapped with adhesive plaster, and the patient dropped asleep before the strapping was quite finished. Likewise while a medical friend was visiting me we heard a lady in the waiting room keeping up a loud, barking cough, which, without yet seeing her, I told my friend was not due to anything in her bronchi. On examination, I found a large polypus protruding from the os uteri, after the removal of which the cough soon ceased. Every aurist also knows of severe coughs occurring in children from a bean or like object in the ear. On the other hand, as we have just said, an expectorant cough cannot be stopped short of expectoration. I knew a man who was the terror of ladies in church, for his cough, soon after he began, changed into a series of rapid little squeaks, while his whole body swayed to and fro and he grew black in the face, until he ended with a sort of hallelujah, which announced that the tough pellet had reached his pharynx. The one indication in such a case is to render the secretion fluid instead of viscid, because in hemoptysis, for example, there may be so little cough that the patient is uncertain whether the blood came from his lungs or from his throat.

But an instructive case, illustrating the value of the sound of a cough, was that of a stout young German in Bellevue Hospital, who, I was told by my house physician, had pneumonia. Just then he coughed, and at once I said that he very likely had pneumonia, but that his cough was not pneumonic, but most probably was due to a foreign body occluding a large bronchus. The sound was like that of laryngeal croup or that caused by an aneurysm. I soon found that no air entered his right lung, and then elicited from him that he had been on a drunken bout and the last thing he could remember was his cracking a filbert between his teeth. After marking the spot on his chest where to cut I had him transferred to the surgical side, where Dr. Willi-ton Wright and Dr. Joseph Bryant operated and found the offending filbert in the designated place.

Now, there is no pneumonic process which works such havoc with lung tissue as that caused by an occluded bronchus. Quite different from the exudate of an ordinary lobar pneumonia which may be absorbed, leaving the delicate walls of the air vesicles intact, this destroys them and then extends to the interstitial connective tissue. There must also be something debilitating in its work, for instead of the exclusive presence of leucocytes which carry away the exudate in lobar pneumonia, we find every variety present of bacteria, such as pneumococci, streptococci, etc., with, of course, their toxins.

But just this result follows the occlusion of the smaller bronchi in the scattered areas of bronchopneumonia. Those little tubes are not constructed to contain anything but air, and if filled with a fluid secretion, especially if viscid, the same thing happens to them that occurs to a whole lobe whose bronchus has been plugged. Bronchopneumonia therefore specially prepares a part for the development of the tubercle bacillus, particularly if preceded by the bronchitis caused by the influenza bacillus, as is shown by the great increase of phthisis after every epidemic of influenza.

Bronchitis is an early and afterwards a constant accompaniment of phthisis. But we become so accustomed to ascribe everything to the presence of the tubercle bacillus in the lung that we overlook the fact that without bronchitis the tuberculosis would remain as isolated there as does tuberculosis in bone. The facts are that in the lung the initial tuberculous lesion is kept from healing by the incessant move-

*Quoted from an instructive article by Dr. E. Mathew Gill, MEDICAL RECORD, April 22, 1911.

ments of breathing. A sore on the shin would not heal if it were briskly rubbed up and down from twenty to thirty times a minute. But in the lung, coughing, particularly if the expectoration be abundant and viscid, makes things worse and worse. Nothing could be more damaging to diseased lung tissue than prolonged hard coughing, for soon every variety of mixed infections supervene, until in the last stages the case is virtually one of general pyemia.

Consumption, therefore, should be treated according to the two principles which should guide in the management of all infections, namely, first, by weakening or lessening the number of the invading microorganisms, and, secondly, by increasing the resisting powers of the system. Now, the open air fortunately acts by weakening both the tubercle bacillus and the pyogenic microorganisms. The human race is the most prone to consumption, because we all live indoors. Hence the consumptive does best according to the quantity of pure air which he breathes, while his vital powers are proportionately increased thereby. His diet also should be of the most concentrated kind, by making him, as it were, a carnivorous animal.

The complication of bronchitis, therefore, should never be neglected. This is best treated by making the expectoration very liquid, and for that purpose oils should be administered. All oils cause a free flow of fluid from mucous membranes when applied locally, as one would find out if he introduced a drop of olive oil into his nose. Many oils, if they enter the blood, are then sent to some mucous surface, to be there excreted as castor ol is sent to the intestine. But castor oil also causes watery flow from other mucous membranes, especially if it does not act freely on the bowels. Hence castor oil should not be given to infants with commencing bronchitis because of their feeble powers of expectorating anything. Cod-liver oil certainly loosens cough, besides promoting good nutrition and increasing more than iron, or any other agent, the number of red corpuscles. But it is linseed oil which acts most effectively on the bronchial mucous membrane, a fact empirically discovered long ago in the use of flaxseed tea. Flaxseed or linseed oil, therefore, is my mainstay against bronchitis, whether acute or chronic.

It is difficult, however, to make a palatable emulsion of linseed oil without it being done in a churn. My formula for this emulsion is:

℞ Olei lini, ʒ ixss
Ol. gaultheriæ,
Ol. cinnamomi, āā ♏80
Acidi hydrocyanici dil., ♏80
Glycerini, ♏190
Syrupi, ʒ vi ss
Mucil. chondri, q.s. ad ʒ xxxii
M. S. One to four fluid drachms.

For acute bronchitis:

℞ Emuls. olei lini, ʒ vi
Morphinæ sulph., gr. i
Chloralis, ʒ iss
M. Dose, tablespoonful an hour after meals.

In cases of acute bronchitis there often occurs a useless irritant cough mixed with the expectorant cough. This can easily be recognized by its husky sound and by sibilant râles, and for suppressing it and rendering the cough purely expectorant a small dose of morphine and of chloral is added, to designate which I write Mist. Olei lini comp. The dose of this for an adult is a tablespoonful an hour after meals. I now never prescribe the old expectorant mixtures containing ammonium chloride, squills, etc., as they are so inferior to the linseed oil. This preparation is very advantageous also in bronchitic asthma where the asthma is consecutive to chronic bronchitis. When severe coughing comes on in pulmonary phthisis I direct the patients to restrict themselves to the linseed emulsion for several days until the cough subsides, after which they can resume their previous line of treatment.

There remains one common source of mixed infections, and that is from the intestinal mucous membrane. But as a year ago I published a paper on this subject (Medical Record, May 28, 1910,) with the title "Acute, Subacute, and Chronic Infection of the Kidneys and of Other Organs by the Bacillus Coli." I will only briefly refer to it. It is as great a mistake to suppose that *Bacillus coli* is a harmless denizen of the intestine as to suppose that streptococci and staphylococci on the skin are harmless because they are always there in health, without injury until some cutaneous lesion allows them to enter. There are a number of similar ways for the colon bacillus to infect the system and cause acute nephritis with high fever and rapidly developing coma; or complicate the course of typhoid fever with new and alarming symptoms; or cause dangerous delirium from an intercurrent subacute infection without fever; or the matting together of the pelvic viscera with caseous exudates closely resembling tuberculous masses, or blindness from choroiditis, etc. I have found, however, that nothing is so common as failure to diagnose the presence of colon bacillus infection, doubtless because both physicians and surgeons have heretofore not had their attention directed to it.

The sad case has recently come under my observation of a lad, ten years of age, brought to me by his parents from East Orange, New Jersey, with the history of a continued fever for over seven weeks, first diagnosed as typhoid fever. I found that ruled out by the presence of 18,000 leucocytes in his blood count, and then learned that he first fell from his bicycle and struck the region of his left kidney. This after four weeks was followed by a sudden discharge of pus in his urine, but his fever continued just the same, with frequent afternoon chills. I was pretty sure that he had a mixed infection of *Bacillus coli,* with some pyogenic organism, and on examination this proved to be the case. Under treatment, both the pus and the colon bacillus disappeared from the urine, but the fever continued. My assistant, Dr. J. Edgar Welch, then found the *Staphylococcus pyogenes aureus* in his blood and made a vaccine culture therefrom, but before it could be used the boy succumbed, with a temperature of 106°. Had the nature of his case been diagnosed earlier, the result might have been materially different.

Our review of this subject of the constant occurrence of mixed infections demonstrates that it is as reasonable to expect the host of pathogenic microorganisms to infect us singly as that a variegated carpet be woven out of one material of the same hue and texture. Whenever we are dealing with an infectious disease a sudden change for the worse in the patient affords us good reason to suspect that a new infection has supervened. A full recognition of this ever-present liability is therefore of very great importance both for diagnosis and for treatment.

70 East Fifty-fourth Street.

SOME OF THE LATTER-DAY ENDEAVORS IN THE TREATMENT OF DIABETES.*

By HEINRICH STERN, M.D.,

NEW YORK.

Inasmuch as we have no knowledge concerning the underlying cause or causes of the diabetic process, it is, of course, out of the question to speak of a causal treatment of the malady. All our efforts directed toward amelioration of the diabetic state are empiric in nature, and our therapy is purely symptomatic. In the following I shall dwell upon some of the symptomatic remedial measures which have been advanced in the last few years.

Physical Measures.—External temperature. In a paper read at the Kongress für innere Medizin in April, 1905, Luthje[1] brought out the interesting fact that in dogs with grave diabetes after the removal of the pancreas the surrounding temperature had a decided influence upon the intensity of the glycosuria, inasmuch as the latter is markedly depressed when the external temperature is high (up to 30° C. or 86° F.) He ascribes the influence of the surrounding temperature upon the fluctuations of the sugar excretion to regulatory processes in connection with the body heat, because the experiment animal, exposed to the cold, in the endeavor to maintain its momentary most important function, the retention of its body-heat, suddenly excretes large amounts of sugar. The same author also tried to employ high external temperatures for the treatment of human diabetes. He had four diabetics under his observation for from one to one and a half months. Of these, two cases were severe, one mild, and the last one moderately severe. In temperatures varying between 15° and 30° C. he also noted fluctuation in the sugar excretion, but not as marked as in the dogs. Under the influence of a high external temperature tolerance (for what is not stated), body-weight and general vigor rapidly increased.

In the discussion of this paper Klemperer[2] pointed out that the experiments of Lüthje tended to clear up some hitherto unexplainable facts of clinical experience. It was known to him for a long time, he said, that a cure at Carlsbad in winter did not agree as well with diabetics as one in summer, and that the beneficial influence of bed-warmth and alcohol upon grave cases of diabetes could now also be accounted for. In the same discussion Kühn[3] mentioned the case of a patient living in Java whom he found affected with a severe type of the disease, and which he had already unfavorably prognosticated years ago. In spite of the ingestion of large amounts of carbohydrates (rice, etc.), the patient was still alive, and Kühn concludes that the patient's prolonged life may be attributable to the relatively high temperature of his abode.

Busquet[4] studied the influence of the external temperature on the intensity of the glycosuria in three cases of diabetes. His tests demonstrated conclusively that the glycosuria constantly decreased when the temperature surrounding the patients was warm, while it increased when it was cold. He never placed his diabetics in temperatures above 20° C. (68° F.), but his clinical findings tallied with those of Lüthje in every respect.

At a discussion at the meeting of the British Medical Association in 1908 on diabetes in the tropics[5] attention was drawn to the frequent occurrence of glycosuria and diabetes in the natives of India, and to the fact that acute cases are rather infrequently met with in the tropics, where the diabetic is not emaciated and his appetite less abnormal. Sir Havelock Charles made the interesting statement that the progress of the diabetic process in the East Indian is often slower than in the European, and that the disease may last twenty-five years.

The foregoing are practically all the references in regard to the influence of the external temperature on the degree of the glycosuria and the course of diabetes which I could gather from a brief search of the literature. I have known from personal experience for a number of years that diabetes occurring in certain districts of Central and South America, irrespective of a diet very abundant in carbohydrates, often runs a protracted and very mild course. This is also the case to some extent with the diabetic affection in certain localities of our own South. A patient from Mississippi since dead from old age (he died in the North) assured me that he has had diabetes for over thirty years. From a number of diabetics, who have repeatedly come from the South to consult me, I know that they lost weight and excreted large amounts of sugar when they were in New York for a few weeks, but that their body-weight increased and the glycosuria decreased soon after they had left the flesh pots of the North for the hot corn and sweet potatoes of their Southern homes. Furthermore, it is a well-known fact that rest in bed is of beneficial influence in many instances of grave diabetes; the good effect thus obtained is, however, universally credited to the rest and not to the bed-warmth.

Without intending to go into statistical details as regards my own observations concerning the question of surrounding temperature and the course of glycosuria, I wish to state my conclusions: (1) The external temperature exerts a distinct influence upon the intensity of the diabetic glycosuria inasmuch as this is depressed by warmth and raised by cold. (2) A temperature of from 80 to 90° F. of the surrounding *dry* air may be employed therapeutically to reduce the degree of a diabetic glycosuria. (3) A surrounding temperature of from 80 to 90° F. may *per se* reduce the sugar output by from one-fourth to one-third. (4) A warm external temperature does not materially influence the acetonemia concomitant with grave cases of diabetes. (5) A warm external temperature has no noticeable influence on mild cases of diabetes, but exerts a salutary effect on moderately severe and severe instances of the malady. (6) The salutary effects of a warm surrounding temperature on the diabetic organism, besides the reduction of the glycosuria, consist of the production of an increased tolerance for carbohydrates and proteids; the increase of body-weight, resistance, and vigor; the lessening of gastrointestinal disorders, and the subduing of neuritic and angiosclerotic pain.

The most efficacious way to obtain the proper external warmth for the diabetic patient is, of course, to let him live in an evenly warm and dry climate all the time, or at least during the period when it is cold in his own town. Unfortunately, it is only a small minority of our patients who can radically change their place of living, even for six months in the year. Patients affected with the severer forms of diabetes and who stay at home during the cold season should live, when out of bed, in well-ventilated rooms heated to from 75 to 85° F. They should wear flannels and be in a very mild perspira-

*Read at the meeting of the Medical Association of the Greater City of New York, March 20, 1911.

tion for one or two hours after the midday repast. They should be in bed, well covered, for from ten to sixteen hours every day, during which time the surrounding temperature of the room may be lowered to about 65° F. The temperature under the bedcovers, however, should be somewhat higher than that of the fully clothed body in a room heated to from 75 to 85° F. To obtain the necessary bedwarmth the hot water bag or the electrical heating pad must occasionally be resorted to. Superheated air or the leucodescent lamp, applied for the usual brief periods, cannot replace the continuously warm surrounding atmosphere, and have no special value as far as the treatment of the severe types of diabetes is concerned.

Electricity. Since the publication of the reports of some French electrotherapists anent the value of high-frequency currents in diabetes, very little has been said in favor of this method of treatment by leading internists. But a good deal has been written disputing or denying the therapeutic influence of these currents on the diabetic process. It is a significant fact that nearly all the advocates of this agent are electrotherapists and not internists, in whose domain the treatment of diabetes really belongs. De Kraft, at the meeting of the American Electro-Therapeutic Association in 1909[6], asserted that five cases of diabetes with pronounced constitutional manifestations and a glucose output varying from 7 to 9 per cent. have remained sugar-free for many months and showed decisive improvement in general health after having been treated with high-frequency currents. He applies the latter preferably by autocondensation, or by the effluve to the insulated patient with grounded metal to the back. High-frequency currents when employed in this manner, he theorizes, regulate the circulation when it is unbalanced through pronounced influence on the sympathetic nervous system, improve the tone of the arterial wall, lower blood-pressure, check the formation of toxins, and strengthen the natural defenses of the body. These currents have a marked stimulating action on cell life and on the nutrition of cells at the farthest point, and increase the reducing power of hemoglobin, thereby augmenting tissue oxidation. There ensue, the same writer continues, increased renal and glandular activity, and larger amounts of sugar appear in the urine for a time, continuing until the glycogenic balance in the liver cells and the muscles is restored, after which, under continued treatment, the amount of sugar excreted steadily diminishes, to disappear entirely in favorable cases.

Tousey[7] remarks that the application of the high-frequency currents may be harmful in instances of advanced diabetes, and that the glycosuria may not yield to this treatment in certain cases. He maintains, however, that the general strength and the cutaneous and other symptoms are improved to such a degree by high-frequency currents that they should form an essential part of the treatment of every case of diabetes, and that there are numerous cases of the affection in which the glycosuria disappears entirely. At the same time he admits that his own cases cannot serve as conclusive evidence of the efficacy of the electric procedures *per se* as he did not insist upon discontinuance of medical treatment. On the other hand, he is able to declare that cases of diabetes which have fared badly under medical treatment alone have improved under the combined medicinal and electric treatment. According to the same author most electrotherapists having obtained beneficial results in diabetics employed the following technique: "The secondary terminals of an induction coil are connected with the internal armatures of two condensors and the spark-gap is between the latter. The outer armatures are connected by a small solenoid, from two turns of which wires lead, one to a metal electrode held in the patient's hand and the other to foot-plate or foot-bath making contact with the patient's foot."

I have seen a great number of diabetic patients during and after their treatment by electrotherapists, and I have myself employed the high-frequency currents, both by effluve and autocondensation, in more than sixty instances of the various types of diabetes. My deductions concerning the effects of the high-frequency currents on the diabetic process are: (1) The high-frequency currents *per se* do not influence in one way or the other the intensity of either the glycosuria, azoturia, or acetonuria. (2) A diabetic glycosuria irreducible by diet cannot be reduced when high-frequency currents are employed in addition thereto. (3) High-frequency currents employed together with a suitable and well-regulated diet will occasionally yield better results as far as the general condition of the patient is concerned than when an antidiabetic regimen alone is being pursued. (4) Eventual benefits accruing from the combination treatment are more lasting when the patient is surrounded by a high external temperature. (5) Mild cases of diabetes are not at all benefited by the high-frequency currents; neither is the preponderating majority of grave and advanced instances of the malady.

Dietary Measures.—The Diet in General.—Three different opinions prevail to-day as to the energy requirement of the diabetic. Some contend that the caloric value of his food should not essentially differ from that of a healthy individual; others, and these are still in the majority, assert that there will ensue a metabolic deficit if sufficient extra calories are not added to his ration; and others again maintain that the nutrition of the diabetic should be kept at a comparatively low level. Each one of these rules is right and wrong at the same time. Adherence to one may benefit one patient and infinitely harm another. Iron-clad rules have no place in the management of the diabetic state. Diabetics affected with a mild type of the disease and above fifty years of age, for instance, will often get along very nicely on a diet of a caloric value similar to that of the normal individual of the same age and doing the same kind and amount of work; in other cases of diabetes, especially in the preacetonemic forms of childhood and adolescence, the energy requirement of the body may demand a somewhat larger amount of fuel, and in many cases of diabetes of the obese and in instances of far-advanced diabetes a low diet seems to be often imperative.

Once for all, it must be understood that a diabetic regimen of rather scant caloric value (25 to 30 calories per day and kilogram of body-weight) is better adapted to enhance the tolerance for both carbohydrates and proteids than is the ordinary, time-honored, highly calorific antidiabetic dietary. Furthermore, it should be remembered that the method of determining the fuel value of the ingesta has absolutely nothing to do with food assimilability and catabolisity in the diseased organism. We must always reckon with the inability of the diabetic organism to utilize rationally many foodstuffs; however, we must not lose sight of the fact that nutriments a diabetic frequently profits by if supplied in

limited amounts may not be entirely assimilated or will often give rise to more or less serious disturbances when ingested in larger quantities as a substitute for ordinarily not well-tolerated foodstuffs. Hence the more recent thought to rather keep down the total nutrition and reduce the intake of all types of food in certain forms and stages of diabetes than to risk the production of untoward phenomena—possible precursors of a fatal issue.

Carbohydrates. The tolerance of various diabetics to certain carbohydrates is dissimilar. This diversity seems to be due in part to the absorptive qualities of the patient. The slower and more imperfect the absorption of the carbohydrate yield the lower will be the degree of the resulting glycemia. This apparent fact may be made use of for therapeutic purposes. Lenné[8], for instance, reminds us that the carbohydrates are best tolerated by the diabetic in that form which is absorbed and enters the blood-current most slowly; coarse, tough, moist bread is therefore better suited for the diabetic than is fine, dry, and toasted bread, and Saratoga chips better than well-mashed potatoes. Hence, in order to enhance the tolerance of the diabetic for carbohydrates, it would be only necessary to render the latter somewhat difficult of absorption. The employment of cellulose in the diet of diabetics, as suggested by Schmidt and Lohrisch[9], means practically nothing else but the ingestion of material which is slowly, if at all, absorbed. They found cellulose of service in such cases in which the glycosuria endures in spite of the total withdrawal of all carbohydrates. While cellulose does not prevent loss of body albumin it has a certain caloric value. These observers have found that patients who could not tolerate the ingestion of 10 grams of grape-sugar or 20 grams of starch could well metabolize from 18 to 36 grams of hemicellulose in the form of a pulverized agar-agar preparation. It goes without saying that sawdust, no matter whence derived and how manipulated, has very little tendency to increase an existing glycosuria; but it is improbable that a diabetic derives any real benefit from material which is ordinarily absorbed in minute quantities only and which is of but small caloric value for the human economy. Suggestions of this sort which contradict all physiological reasoning must never be taken seriously; they are only too often a bid for royalties from the manufacturers of patent foods.

Clinical experience has demonstrated that the ingestion of a single type of carbohydrate may occasionally temporarily improve certain cases of grave and far-advanced diabetes. Such cases exhibit an apparent elective tolerance for *one* specific carbohydrate. Oatmeal is one of these carbohydrates; and there is no doubt that, if no other carbohydrate be ingested at the same period, the glycosuria as well as an existing acetonuria may be depressed transitorily. Oatmeal in respect to lessening the glycosuria exerts no effect other than that following the intake of material rich in cellulose. Large amounts of oatmeal, as prescribed in von Noorden's oatmeal diet, exhaust the activity of the special organs concerned in the elaboration and absorption of the nutritive principles; and but small amounts of these enter the blood-stream at any one time. There is an additional factor precluding the total absorption of the carbohydrate derived from the oats, namely, being lodged in the intestinal tract for an unusually long period, a large portion of the oat-carbohydrate undergoes fermentation and is not absorbed. Of course, this does not explain the diminution of acetonemia. Klotz[10] believes that oatmeal is transformed beyond the stage of sugar and is taken up as an aglycogenic, anhepatic carbohydrate, thus reducing the acetonemia. The antiacetonemic effect of an oatmeal diet, however, is commonly grossly exaggerated; such an effect ensues in comparatively few instances of diabetic acetonemia, and it may in such cases be just as often procured if some other single carbohydrate, particularly rice, is being ingested. Fresh milk, especially when skimmed, is in my opinion that anti-acetonemic single carbohydrate which is best suited in advanced cases of diabetes. Some of my cases of very grave diabetes were not only rendered sugar-free, but also acetone-free for from two to three weeks when they were under an exclusive skimmed milk-yolk regimen.

Proteins. In every grave case of diabetes even the carbohydrate derived from the protein molecule is not utilized. The albuminous ingesta do not only augment the glucose output in such cases, but are apt to putrefy in the alimentary canal, whereby butyric and valerianic acids, the precursors of the acetone bodies, are formed. In instances of this kind the proteid intake should invariably be kept at a minimum; and it is best to restrict it to the ingestion of but one type during a given period. The so-called vegetable days purport a diminished food intake, especially of proteid material. To all intent such days are practically starvation days because nothing but cellulose and some fat are partaken of. On account of the insufficient nutrition the glycosuria is, of course, diminished, but the acetone bodies appear in increased amounts. For this reason, the much-heralded vegetable or starvation days should be reserved for comparatively mild cases of diabetes, as for instance for those occurring in the obese; in grave types of the malady such dietary stunts are entirely out of order. Vegetable days will only have a beneficial effect when large amounts of fat yielding no volatile fatty acids, and consequently giving no occasion to the production of the acetone bodies, are ingested together with the vegetables.

Fats. Concerning the fatty ingesta in diabetes, especially when this is complicated with acetonuria, nothing new has been advanced since my publications on this subject in 1904, 1905, and 1906. I occupy at this day the same standpoint as then. In the following I shall quote from some of my former publications[11].—If we wish to cope successfully with acidosis without aggravating the diabetic condition we can neither add comparatively large amounts of carbohydrates to the nourishment for any length of time nor can we in most cases increase the amount of proteid substances. Therefore, nothing remains but to turn again to the fats, that is to such fatty ingesta which, if at all, contain but small amounts of fatty acids of low molecular weight. The fatty acids which may be considered mother substances of acetone bodies are valerianic, butyric, and caproic acids; fatty acids of high molecular weight, like palmitic, stearic, and especially oleic acids, yield comparatively little acetone. Hence, butter and cream are productive of largely increased acidosis, while lard, suet, and particularly olive oil do not cause a very marked augmentation of the acetone bodies. The clinician who is attending a case of grave diabetes complicated by pronounced acidosis, finds himself in a dilemma. Were he to prescribe a diet consisting of nothing else but small amounts of proteids and large quantities of lard, suet, or olive oil, the patient would soon be tired of this regimen and his nutrition would not only be not improved but his

digestive organs might become seriously disordered. Besides, and this should not be forgotten, the vegetable oils are, as a rule, not well tolerated if they are used in larger than the ordinary amounts, and lard and beef suet can neither be relied upon for suppressing an already existing acidosis nor to improve the nutrition of the diabetic organism. There is only one fatty article of food which I found well adapted to the needs of the diabetic organism when acidosis is established—this is the yoke of the hen's egg; I have but on two occasions seen it to produce or increase the acetone substances, and but in one case to cause digestive disturbances. Partaken of in the raw or semi-raw condition, fresh yolks may be consumed in large quantity without calling forth satiation or fulness. The rationale of the "yolk cure" in diabetics I ascribe to the following main factors: (1) Yolk-fat, in its native state, in suitable admixture is well borne and assimilated by the vast majority of diabetics. (2) The great absorbability of yolk-fat; the residue left by yolk-fat in the feces is smaller than that of any other animal fat. (3) The fat-components of the yolk of the hen's egg, palmitin, stearin, and olein, yield no, or hardly any, volatile fatty acids, and consequently give no occasion to the production of the acetone bodies. (4) The large amount of lecithin contained in the yolk tends to the restoration of nerve force and acting as a general reconstructive ameliorates the cachectic condition. (5) The occurrence in the yolk of a diastatic ferment assisting in the conversion of amyloid substances. (6) The property of the yolk to stimulate the digestive secretions.

Medicinal Measures.—On account of the general application of the dietary methods to the management of the various glycosuric states and on account of injudicious prescribing and the polypharmacy of former years, medicinal treatment has for a number of years been relegated to the rear. In the degree, however, in which the influence of diet on amelioration of all the forms of mellituria has been overestimated, the potency of a number of medicinal agents on the various substrata of the glycosuric symptom is nowadays unquestionably underrated (Heinrich Stern)[12]. All medicinal substances thus far employed in the various forms of diabetes are, at the best, only symptomatic remedies. Rudisch[13] advocates the use of atropine sulphate and atropine methylbromide in diabetes. He asserts that the action of atropine causes reduction of sugar excretion and increase of carbohydrate tolerance. He observed that glycosuria disappeared more rapidly when atropine was added to the usual antidiabetic diet than when the latter alone was pursued, and that traces of sugar remaining in the urine when dieting were entirely suppressed when atropine in sufficient dosage was administered. According to the same author, the influence of atropine in increasing carbohydrate tolerance manifests itself in two ways. An amount of carbohydrate sufficient to cause glycosuria in a patient whose urine has become free from sugar but is not taking atropine will be well tolerated as soon as the atropine is administered. Again following protracted administration of atropine the tolerance for carbohydrates increases much more rapidly than after a period of anti-diabetic diet alone. He has given as an initial dose of the methylbromide 2/15 grain t.i.d. to adults, gradually increasing this by 1/15 grain until 8/15 grain t.i.d. are being taken. The initial dose of atropine sulphate should be 1/150 grain t.i.d., that may be gradually increased to 1/20 grain t.i.d. The author asserts further than these very large doses of atropine are well tolerated, provided the initial dose is small and the increase gradual, and that it is not necessary to administer the maximum dose in the majority of instances.

The employment of atropine in diabetes is not of recent origin. In an article on "The Glycosuric Symptom of Disease and Its Medicinal Treatment," which appeared in the *Journal of the American Medical Association,* March 14, 1903, I stated that glycosuria on the basis of a traumatic neurosis sometimes yields to belladonna or atropine. In the same paper I mentioned that, generally speaking, the neurogenous type of glycosuria is the one in which medicinal treatment seems *à priori* indicated, and among the various medicaments propounded for that purpose I also named belladonna. New, however, is the large dosage of the drug as advocated by Rudisch. I have employed atropine methylbromide, according to his method, in about one dozen cases of moderately severe and grave cases of diabetes—in more cases I did not dare to. In all these cases there ensued more or less pronounced atropine poisoning; in two cases of the moderately severe type the glycosuria disappeared after a few weeks' dieting and the administration of atropine, an increased tolerance for carbohydrates was not noted in these cases thereafter; in none of the remaining instances, which were nearly all of the grave type, did the atropine produce any other effects than those of a toxic nature.

NERVOUS DISORDERS AND THE NEUROLOGIST IN RELATION TO THE PROFESSION AND THE PUBLIC.*

BY TOM A. WILLIAMS, M.B., C.M. (EDIN.),

WASHINGTON, D. C.

MEMBRE CORRESPONDANT DE LA SOCIÉTÉ DE NEUROLOGIE ET PSYCHOLOGIE DE PARIS; MEMBER OF THE AMERICAN ASSOCIATION PSYCHOPATHOLOGISTS, ETC.; NEUROLOGIST TO THE EPIPHANY FREE DISPENSARY.

IT is unfortunate that the name of neurologist has been assumed so generally by charlatans without pretensions to even the elements of medical science and skill. Of course, we medical men know the

* Read before the Tri-State Medical Association of Virginia and the two Carolinas at Raleigh, N. C., February 23, 1911.

difference; but the laity may be grossly deceived. But of the other term, "psychotherapeutist," coming within the scope of my paper, a clear differentiation is not always made even by physicians, who have allowed medical amateurs of various kinds to preëmpt the psychic treatment of disease, to the great detriment of the public and with a distinct diminution of honor to the medical profession, for the fact that we have permitted the intrusion of any blatant pretender to psychopathological knowledge indicates to the public our own shortcomings in that science.

The functions of the neurologist of the old school, some of whom survive, were confined to refinements of diagnosis in matters of organic nervous disease, in most of which treatment, as then conceived, was of little avail. This is nowadays regarded as a very small though still essential part of a neurologist's work. Although of course it is impossible that all and sundry can learn from him, however excellent a teacher, diagnostic refinements which have taken him years to acquire, yet a modern neurologist should be a source from which should flow a fertilizing stream of knowledge conveying at least the broad principles of the advances of neurological science and art. These are tremendous, and only one who specializes is capable of compassing and estimating them justly. The service of acquainting his professional brethren and the laity with the advances of neurology is the counterblast and antidote against the always pernicious doctrines of the psychologist-amateur, the crack-brain enthusiast of psychic phenomena, the religious doctrinaire who affects the art of healing, and the most widespread of all, the advertising charlatan who seizes upon and perverts each new scientific acquisition with which at once to terrify and give promise of cure to a credulous public. The more this is done, the clearer will medical men see that neurology, like the rest of medicine, perfects itself by observing and analyzing phenomena which appear to resemble one another, until characters are found which show their essential difference. When this is done the phenomena are regrouped in another synthesis or series according with characters which are essential. These principles in general medicine have led to such distinctions as those of renal from cardiac albuminuria, typhoid from typhus fever, catarrhal from croupous pneumonia, and scrofula from neoplasm. The groupings may be illustrated by that which brought together pulmonary phthisis, tabes mesenterica and struma cervicalis into the common rubric of tuberculosis. It was by these means that, from the layman's rubric of "paralysis," Duchenne was able to separate motor disability into the three types of spastic, flaccid, and ataxic. Since then more numerous distinctions have enabled us to still further classify these types, and in combination with sensory symptoms and modification of the reflexes to construct a nosology which would have been unrecognizable fifty years ago.

The syntheses of modern neurology are perhaps best illustrated by the myopathies and the dyskineses. The separately described types of muscular atrophy, Landouzy-Déjérine, Erb-Klumke, pseudohypertrophic, facioscapulohumeral, etc., after being first differentiated from the spinal hyopathies and the neural degenerations, are now grouped together into the nosological entity of primitive muscular dystrophy. Analysis of dyskineses shows that their fundamental character cannot be determined by tonicity, clonicity, or by situation or intensity of movement, but must be ascertained by its genesis above all, although certain subsidiary characters are often confirmative. By this, the usual process of clinical medicine in differentiation, Brissaud demarkated the tics, the knowledge of which is so important in the prognosis and treatment of nervous disease. But the neurologist, like all scientists, does not stop here. He knows that only by the experimental method are some problems to be solved. It is by the application of this method that the phenomena of hysteria have been elucidated. In producing at will by psychic means hysterial phenomena, and by removing them when desired, the psychogenesis of this disorder has been clearly established. Not only this, but psychogenesic mechanisms have been and are being studied in animals. The epoch-making work of Pawlow need only be mentioned, as it is so well known.

These clinical supplements to post-mortem studies lead us to divide the causes of functional perturbations of the nervous system into three classes. 1. Alterations of the structure of the nervous system, as by inflammation, infiltration, degeneration. 2. Alterations of the medium in which the neurons are to perform their work by chemical substances, whether infections, intoxications, or perverted secretions. 3. Alterations of the forces by means of which the neurons act harmoniously with one another.

Only when these dynamic disorders are confined to the lower nerons should the term neurosis be applied, *e. g.* angioneurotic edema and other disorders are entirely beyond the control of the patient by any psychic means whatsoever. But when the disorder is generated, either from within or without, by impressions upon the sensory apparatus which arouse and associate themselves with the stored-up impressions of other portions of the cerebrum to form a psychological unit known as idea, whether accompanied by emotion or not, then we are entitled, and indeed compelled, to use the term *psychosis* for such a disturbance. The symptoms of hysteria certainly arise by means of this kind of mechanism. It is a moot point whether the symptoms of psychasthenia also arise thus. At all events, it is quite clear that an understanding of this genesis will prevent a clinician from confusing hysteria, really a psychosis, with such a neurosis as excessive vasomotor liability. The mixed term psychoneurosis is no more rational than are such exploded parallels, typhomalaria and typhopneumonia. There is no more essential connection between psychosis and neurosis than between typhoid, malaria, and pneumonia.

I have found that a grasp of these principles greatly aids a practitioner in knowing when he requires to consult a neurologist, for he will not be content with such a vague and indeed unintelligible notion as "hysteroneurasthenia," as expounded in the textbooks. If he is a clear observer, his experience has shown him the frequent failure of the therapeutic blunderbus recommended for these cases; and he wants to know why he failed with some and succeeded with others. Even though he can eliminate structural disease, he often finds himself incapable of a pathogenic diagnosis, and it is then he realizes the need of assistance. Nothing has been more gratifying to me in Washington than the successful issue of cases where patients have been seen for the purpose of making such an analysis in order that the physician might feel that he was directing his therapeutics in the right way.

This is the more so as it is impossible for a neurologist to himself treat all the cases he sees, time lacking and energies being limited. Besides, every doctor who cures a neurological case after consultation feels his power much added to, and himself becomes a sun of flaming ray to scorch up the weed of charlatanry. A relation of a few such cases will be instructive.

Case I.—Hysterical typhlitis after appendectomy. A girl of twenty was referred by Drs. Watkins and Stavely because of recurrence for three months of right iliac pain with nausea and vomiting, but normal temperature and pulse. Two months before, the right iliac fossa, controllable by indirect suggestoms and found little changed, though containing a concretion of lime. At the time the ovaries and gallbladder were found normal. The pains recurred every few days, lasted some hours, and were relieved by morphine or the Scotch douch. Examination showed only a psychogenic hyperesthesia in the right iliac fossa, controlable by indirect suggestion. Some sacral atonia, a slight retroversion, and intestinal sand could not explain a manifestly psychogenic tenderness. So after a few days, Dr. Watkins, armed by conviction derived from the consultation, entered the fray, and after a struggle of nearly two hours convinced the young woman that determination to conquer a longing for the comforting and anodynes which sickness brings would cure her. She went back to Illinois next day, and has remained well. Such rapid success is not common. The following similar case illustrates the need of persistence in persuasion.

Case II.—Coccygodynic neurasthenia. A spinster of thirty-four was referred by Dr. Lemon because unbenefited by uterine suspension, amputation of the coccyx, and other gynecological measures. She was lying stiffly in bed for fear of hurting the coccyx, with intense right iliac pain and tenderness. I found the latter modifiable by suggestion, as was the stiffness. There was a false, *i.e.* volitional, Kernig's sign, and the reflexes were sluggish. She wore the martyr smile. She professed anxiety to recover and to go to work. Her condition was manifestly psychogenetic; but her sister's belief in its organic nature hindered recovery, in spite of the persistency of Dr. Lemon. But at my instigation he kept persuading until finally improvement began, and one day the young woman determined to put it to the proof, went to work, succeeded in the fierce struggle against giving way, and is now more capable than she has ever been before.

Case III.—Hysterical hemiplegia from worry; simulated Babinski sign. A chief clerk, aged 54, always rather peculiar in disposition, was seen with Dr. Clayton because of hemiplegia which occurred suddenly, apparently in his sleep one night. He had no pain but was numb all over, could not get up properly, stuttered, lisped, his tongue seeming tied. At 11 A.M. Dr. Clayton found the right eye wider than the left (equal next day), and that all movements could be made, but the right grip was weaker than the left. He thought it hysterical on account of the history. But as in a few days the patient became completely hemiplegic, I was called in consultation. The reflexes were equal and not exaggerated, but volitional contraction suppressed the right gluteal reflex. The right toe extended on stroking the sole. This, however, was done voluntarily. We shall discuss this later. The right arm was quite motionless, but moved when he yawned; the leg moved with difficulty; the contralateral synergic responses were, however, equal. The patient stuttered in speaking, and sensibility was normal. Psychic examination. This showed the pathogenesis. He was particular to the extent of old maidishness and was dyspeptic all his life. He was subject to petty worries and easily annoyed. Lately he has feared losing his position to a pushing subordinate and little family worries have occurred. A son had studied medicine; and he himself often had gone to the lectures; he understands the mechanism of his affection to be "a failure of the will to connect with what moves the arm." He defied me to make him move the arm by suggestion. Treatment. Entirely acquiescing, I explained the fault was not in the connection but in the controller himself, and admitted my inability to make his arm move, but declared that he could do so by practice. Having disarmed him thus, I easily inaugurated movements on the spot by suggestion, and he flexed and rotated the forearm and moved the fingers. Then his wife and doctor were called and shown the improvement. An encouraging prognosis was given, and a week's horseback tour advised. The iron was not struck while hot; so he did not recover for some time, but is now well. This case is a strong recommendation to neurological consultation. The simulation of Babinski's reflex could not have been detected without a very thorough training in clinical neurology. Again, the psychotherapeutic tact which acquiesced in his rebelliousness emanates from a clear grasp of the psychopathology of hysterical incapacity. It was only after I had made him move that I explained to him the genesis of his affection, showing that it was in the first place a defense reaction against his business and domestic troubles, a desire to escape from which caused a reaction in the semiconsciousness of a troubled night,* which dramatized one of the pictures he had memorized as an amateur of medicine.

Case IV.—Hysterical phobia vertigo founded upon slight arteriosclerotic occurrences. A clerk of 53, sent by Dr. H. A. Parker; the complaint was fearing crowds and anticipating evil. A hypertrophied heart, a blood pressure of 200, albuminuria and vertigo had been improved by nitrites, warm baths, and less meat. Pressure now 155. Lues treated seventeen years ago. Now he often veers in walking and has once fallen in the street. He worries over small matters. He has "blank" attacks lasting for a second or so. Reflexes: slight inequalities everywhere. Sensibility: attitudes not clearly perceived especially on right wrist, otherwise normal. Motility: normal save a slight spread of the right foot in walking. Rotation tests negative, no nystagmus. Psyche: no defects nor anxieties. Thus cerebellar vestibular anomalies could not be the cause of the alleged vertigo. So it was explained that his fear of vertigo was suggested by his former real vertigo which had greatly improved so that he could be reassured; for there was no organic disease of the nervous system other than a slight arteriosclerosis. He was not likely to grow worse if he followed his doctor's advice. He continues at work six months later.

Case V.—Supposed hysteria from cardiac dyspnea in a Christian Scientist. A woman of 64 was recommended by Dr. Ramsburg because the Christian Scientist healer was feeling her limitations and

* See author's "Genesis of Hysterical States in Childhood," also articles on "Hysteria," Medical Record, October 2, 1910; *International Clinics*, August, 1908; *American Journal of Medical Sciences*, August, 1910.

"wanted a nerve specialist." It is possible that she believed a neurologist was more likely to diagnose a psychogenic affection and thus indirectly justify her treatment. The poor woman had for months been forcing herself to ignore the intrusins of "mortal mind," and had made a valiant struggle against insomnia, dyspnea, anguish, and fear, due to a greatly hypertrophied heart with failing compensation (pulse 120), and arteriosclerosis, possibly contributed to by an old hyperthyroidism. There was no albumen. She was advised to go to bed, take light diet, and call in a proper doctor; and I was most explicit to the healer who was convinced, in spite of herself, that here was something against which her doctrines availed nothing. They did not go to the doctor whom I had recommended; but I am told that the woman's condition is now tolerable.

The Mental Alienations. A most important function of the neurologist is presented by cases of severe nervous perturbation due to the prodromes of some major psychosis leading to legal insanity.* An example of such a case was referred by Dr. M. E. Miller.

Case VI.—"Hysterical" behavior due to dementia precox. It was a youth of 23, who declared to me: "I can hardly express my trouble, not finding the right words. It signifies vocation and environment, *i.e.* to find the pursuit which fits me." This declaration was suspicious, although many an ill-instructed lad might at times have rational doubts as to his career, and become mentally disturbed by difficult environment such as this boy's, who was in the government service after a university course paid for by working his way and by the hard earnings of his father, a mechanic. The psychoanalysis, however, soon revealed that during a previous breakdown, "confusedly and deferring to his father's authority and outside influences, he yet felt within a light penetrate his brain with prophetic fire." A ball of fire in the sky was later interpreted as a sign; but the "Chancellor explained it was simply Jupiter.' Two years later, the "sign of love," "the call of man for his mate" brought him to the District of Columbia. The analysis is too long to detail, suffice it to say that several weeks of insomnia produced an excitement and erratic and libidinous behavior which drew attention. It was not difficult to diagnose dementia precox. The importance of the diagnosis is the sparing of expense to a family ill able to afford it. Loss of memory is often the first index of some neurological condition. To determine the source of this sometimes needs all available technique.

Case VII.—Supposed hysteria due to amnesia by sclerosis. A woman about 50, referred by Dr. Balloch, is an example of aphasic amnesia of organic cause. It is characterized by emotional distress and fear of insanity due to the loss of power to express the thought in words, although the patient feels that the idea is there, and can sometimes explain it in a periphrasis. My patient, even after ten minutes study, is unable to recall and relate in words the story of Noah Webster. The following is her account with much questioning. It begins with "N. Noel? No. Noah? No. Newel? No. Noah? That's like it." Recognizes Webster. "College? Yale. Profession? Lawyer. What did he do when young? Taught school. What else? Don't know. A book? Yes. Kind? Don't know. Dictionary? I suppose. Date? 1790, too late. Why? My idea earlier but I don't get the rest. Was it in war time? The other one. Name? Against whom? All other kinds in United States. Civil? Yes, that is it. Date? 1861. Did Webster live then? Too soon. Against whom then? He was not old enough, don't remember now though he taught school." She did not recollect the capital of Germany, nor in what country Edinburgh was situated, although she had once been a school teacher; but she could reply quite intelligently to any question if she remembered the word to answer, and she could read and write; but in the latter there were frequent omissions of words, of which she was quite aware and which she deplored. She could not recall the word she wanted, although she at once recognized it when proffered. Her condition intermitted more or less, but never became normal. The importance of the case is its diagnosis from a purely psychic amnesia; and to ascertain whether it was not due to a chronic intoxication or whether it was caused by the cerebral necrosis of arterial defect; on the latter diagnosis I finally decided, as metabolic treatment failed to ameliorate the condition, and its oscillations were very slight. That it was not a psychic case is shown by its entire unamenability to psychotherapy, by its genesis apart from any psychological cause, and by the nature and extent of the responses to psychometric tests too long to detail here.

Simulated Disease. The detection of this is often a task of the neurologist. In my case of simulated hysteria described last year at the Tri-State Medical Association* you will recollect that a criminal had been so often examined by physicians unaccustomed to the technique of clinical neurology that he simulated consciously the hemianesthesia of the hysterical type, *i.e.* absolute anesthesia, extending to and ceasing at the mid line, and affecting all segments equally in the same limb. Although, of course, he was not amenable to persuasion, he was detected by reacting to pain while his attention was diverted.

Case VIII.—Simulated quadrantic hemianopsia. An ex-sailor of 41 was referred by Dr. Henning to whom he had been sent by Dr. Burch because of inability to perform more than light work. He has a small pension and has applied for an increase. He declares that he was believed epileptic in the navy, and that since the accident of falling out of his hammock while asleep fifteen years ago, after which he was totally blind, remembering nothing, life has seemed a dream; it is hard to understand people; his memory is poor and he is very nervous on the street, not being able to see out of one side of the eye, and bumping into objects. As the hemiopic person always carries his head turned towards the side of the sound retina and has to turn his head still further to see objects on that side of him, I suspected this man at once; for there was no deviation of the head. I accordingly nonchalantly asked him to move a dark screen so that he could be hidden while stripping. He did this in a dark corner without any head movement to indicate loss of vision in the periphery of either visual field. But on approaching the field with test objects in the usual way, he declared that objects were only seen as they impigned upon the right upper retinal quadrant, *i.e.* below and to the left. As to his apparent good faith there was added a loss of the right Achilles reflex, and some inequality of others along with an

*See "Differential Diagnosis of Neurasthenia," *Archives of Diagnosis*, January, 1909.

* See Transactions of the Tri-State Medical Association, 1910; also *American Journal of Insanity*, October, 1910.

uncertainty of the sensibility of the diapason on the malleoli it was necessary to confirm either the patient's opinion that his visual field was restricted or my own that it was not. As the pupils reacted normally and the optic papilla was not diseased, an anterior lesion was excluded. The diagnosis of simulation was clinched by his winking when I placed before the right field of the right eye the percussion hammer with which I was ostensibly testing the orbicular response to a tap on the facial nerve. This took place, both from above and below, on the left and right side, and conclusively proved that he actually perceived objects with all parts of the visual field. It is hardly conceivable that such a syndrome had occurred by suggestion in medical examination; and I believed that it was intentional. This was proven when he visited me for the second time, after I had told his doctors what I had found; for on presenting the hammer in the same manner as before no wink occurred, the patient staring fixedly before him and declaring that he saw nothing except when the hammer was below to the left. It was, however, easy to show that he was feigning, by holding opposite the midhorizontal plane of the eyeball just within the visual field two strips of color. He saw only the one color; and when they were reversed similarly. But he saw the color which impigned upon the blind field and not that upon the field which saw. Hence, his feigning was deliberate, as he had suppressed the reaction by which it had been formerly detected, and yet still showed, unknown to himself, that his blind field saw.

The Traumatic Neurosis.—A clear understanding of the psychogenesis of this disorder has emanated in recent years mainly from the labors of Babinski and his associates. Nowhere is there more need of a clear differentiation of that which is due to disorder of the nutritive functions and that which arises purely from a false belief giving rise to morbid apprehensions. In the MEDICAL RECORD, October 2, 1909, I endeavored to show and illustrate by the analysis of a successful case the mode of genesis of this affection. It was there made clear that a knowledge of neuropathology and diagnosis was necessary to form a correct opinion in these cases, for a general presumption is liable to error. The efficient cause of this disorder was the suggestions either derived from others after the accident or inherent in the milieu in which the patient had lived before. I need not therefore again elaborate the argument concerning this important subject.

Brain Tumors.—The proper treatment of intracranial neoplasms, their early removal, is possible only when diagnosis is made before most practitioners even suspect a tumor. The need of a thorough examination by one versed in neurological technique was insisted upon at a recent symposium here and need not engage us to-night.

CASE IX.—Barking and bowing tic of hysterical type. A striking instance of the success of rational procedure where empirical ones had failed occurred in a young Hebrew in North Carolina with iliocolitis. He suddenly developed on going to bed one night an intense clonic contracture of the recti abdominis and diaphragm. This recurred every night, often keeping him awake for hours. It became less and less controllable, and soon occurred on sitting during the day. Then it began to come on standing, until his life was a burden. The application of electricity with the fervid assurance of its efficacy had made no impression, nor did "powerful and infallible" medicines. The boy came to Washington and was at once referred to me by his physician, Dr. T. C. Martin. On recognizing that the disorder was a tic of hysterical type,* the psychomotor discipline devised by Brissaud was employed. In this case, it consisted of inducing the patient to perform slow, even, rhythmical contractions of the recti, while taking slow, deep breaths. In this way, control was gained over the muscles, so that when the paroxysms were about to begin he had now a means of mastery, and substituted the newly learned movement for the automatic one which formerly took its own bent. He learned in one day; too quickly as it proved; but after a slight relapse two days later, another sitting cured him; and he was shown recovered. Even for this very simple case, empiricism had failed where a little psychopathological knowledge reached the cause, and led to the very simple means used for its removal without either psychoanalysis or reconstruction of the mentality. Such a symptomatic cure must of course be extended to a pathogenic one, *i.e.* the reeducation of the patient's hysterizability.

Laboratory diagnosis cannot completely replace clinical acumen. Before the Wassermann reaction and examination of the cerebrospinal fluid were available, perhaps the most important diagnostic function of a neurologist was the detection of syphilis of the nervous system. There is a widespread belief that these laboratory methods have put an end to the need of the technique of clinical neurology. This is by no means the case; for of tabetics only 50 per cent. react to Wassermann's test, and even cytological examination may be negative for a time in a few cases. I have already reported (*New York Medical Journal,* March, 1910) two "neurasthenic cases which by means of refined clinical methods were correctly diagnosed as preparesis and pretaboparesis, and in consequence of the early treatment thus made possible are now completely recovered. I wish here to report a case of pretabes in which the clinical signs enabled me to persist in this diagnosis in spite of a constantly negative Wassermann reaction, and the clearing up of bladder symptoms under local treatment. By pretabes is signified the pathological condition of chronic luetic leptomeningitis involving the spinal roots or cranial nerves.† The irritation of the nerve fibers is characterized clinically by pains of variable kind, paresthesiæ, hypoanesthesiæ, rarely hyperesthesiæ of the limbs, trunk, and viscera; usually diminution of the reflexes, hypotonia, some asthenia, and occasionally temporary paralysis and muscular atrophy. I persisted in this diagnosis because of the radicular distribution of intermittent burning and twisting pains on the internal surface of the right leg, along with a loss of the Achilles and right patellar and gluteal and diminution of left patellar and bulbocavernosus reflexes, along with a hypotonia of the hamstrings and a slight Rhomberg of the right leg, with diminution of deep sensibility and slight hyperesthesia of the lower lumbar and upper sacral segments. It was not until after a mercurial course which cleared up the symptoms for a month that a lumbar puncture was made revealing an increase of plasma cells. Ehrlich's salvarsan was then given, with relief for only a week, and mercury has now been resumed. In the meanwhile a partial positive Wassermann reaction declared itself. Thus.

†"Pathological Prodromes of Taboparesis," MEDICAL RECORD, February, 1910.

the correct interpretation of neurological signs has spared five months of degenerative changes to a patient to whom early treatment is of the profoundest importance.*

Ataxia is a symptom which does not mean tabes in all cases. It sometimes comes from cerebellar disease,† sometimes from disease of the peripheral nerves, and may be psychic occasionally. It is a delicate neurological task sometimes to make these distinctions, which are of the greatest importance in prognosis and treatment. I have under observation three cases of cerebellar defect: one of eleven years standing due to malarial thrombosis for which nothing can be done; the second of unknown origin similarly hopeless; a third, seen recently, probably of familial type. A fourth case, a child of four, was the progeny of a diabetic mother and is possibly due to an agenesis of the cerebellum. A fifth case recently seen at Norfolk in consultation with Dr. Lile of Lynchburg, showed marked ataxia of cerebellar type. As it was a child under seven one might have suspected congenital dystrophy but a progressive dementia made one believe it a case of juvenile paresis, which opinion was confirmed by a positive Wassermann reaction. In the differentiation of convulsive movements, too, neurological knowledge and skill are essential. As for example in the convulsive attacks of symptomatic epilepsy, of which I have spoken in a recent article, giving examples in which early diagnosis led to proper treatment and arrest of the causative process, which was sclerogenic toxicosis. It was adequate neurological diagnosis again which differentiated the condition of these patients from epilepsy proper.

Three Cases of Narcolepsy.—Fits of various kinds have to be differentiated from one another, not only as to character but as to pathogenesis. I have recently seen four cases having narcoleptic attacks. One occurred in a young man of nineteen from cyclical intoxication, possibly through pancreatic disorder, as he showed the Cammidge reaction in the urine and was intolerant to meat proteid. It was possibly congenital, as his sister has gone through a depressive episode of confusional type of metabolic origin. The second case occurred in a boy of eighteen, who on several occasions lost consciousness for three hours, the first time after drinking cold water on a hot day. He has a slow pulse, and eats enormously of buns and ice cream and drinks a large amount of coffee. There were no epileptic phenomena except irritability and sullenness of temper. A third case was a girl of twenty-one who gained forty-five pounds in weight in four months, and had sudden dimness of vision and loss of memory. Suspecting pituitary enlargement, the visual fields were examined, and showed respectively lateral and inferior partial scotomata. The *x*-ray showed a deepened sella turcica. It would have been gross error to have given bromides to any of these cases. All are doing well, the first and second upon proper diet and hygiene, and the third by *x*-ray treatment of the pituitary hyperplasia, which immediately terminated the narcoleptic attacks and removed the headaches and depression. But it was neurological experience which permitted of the diagnoses.

Intermittent Claudication of Labyrinthine Vessels Mistaken for Psychasthenia Cured by Opotherapy.—Vertiginous attacks in a woman of twenty-nine, referred by Dr. Barton, had persisted for seven years. Groaning (roaring) in the head ushered in the attack. An aurist had treated her without avail. She frequently fell, always forward; and sometimes vomited during the attack. A perfectly natural phobia had developed in consequence and caused Dr. Barton to diagnose phychasthenia and thus send the case for advice. The absence of objective neurological changes as well as of initial psychic disorders, and the presence of dermatographia made me believe this a vasomotor neurosis, due perhaps to adrenal aberrance. I recommended adrenalin to increase vessel tonus. She has only had one attack since taking it, and is in every way in better health. Now this case might have been diagnosed epilepsy, cerebellar disease, or hysteria as well as psychasthenia by an observer not well acquainted with the interpretation of neurological signs. And an operation, bromides, or psychotherapy might have been tried without benefit to the patient, and to the discredit of our profession.

The Relics of Poliomyelitis.—Only by a skilled neurological examination is it sometimes possible to predicate a former poliomyelitis. I have seen a number of cases lately which illustrate this. Complete paralysis of one serratus magnus was all that remained of a poliomyelitic attack, which had caused unilateral tremor, hyperesthesia, and oculo motor paralysis with some weakness of the arms, in a woman of 30, referred by Dr. Dunlop. Another case which had not been diagnosed during and after the acute phase, although examined by three well known Boston men, was referred to me four months after the attack for electrodiagnosis by Dr. Dunlop, who suspected that a weakness of the legs might be poliomyelitic. I found the Achilles reflexes absent and the right aural muscles irresponsive, and the left hardly so even to strong currents. On the one side, the excitability of the anterior tibial group was diminished, and on the opposite side that of the peroneal; and one rectus abdominis was less excitable than its fellow. The diagnosis of multiple neuritis, which had been given, was utterly inconsistent with so unequal a distribution of muscular atrophy and the absence of sensory symptoms. So I considered the case one of poliomyelitis, a diagnosis which the patient's mother saw confirmed by Starr, Schaffer, and Holt of New York. A proper neurological diagnosis in the first place would have spared this child much delay in treatment.

Sexual Aberrations.—In disharmonies of the sexual functions, neurologists may afford much help to practitioners unaquainted with psychopathology. It is necessary to find out whether simple asthenia, hysterical fixed idea, or psychasthenic obsession or phobia is responsible for a psychic abnormality of the healthy sexual life. Besides this, the effect of shame, which has become attached to much of the sexual life through prudish misconceptions of social relationships, is often an important element in the life of neurotic patients. After it has been unraveled by a psychopathologist, I believe it quite possible that an intelligent physician interested in this aspect of therapeutics might well conduct the reeducation and guidance of such patients. It has not yet fallen to me to collaborate in such an arrangement, all the doctors who have consulted me in such cases preferring that I, myself, should conduct the treatment, and this is far

*See "Treatment of Parasyphilis of Nervous System," Transactions of the American Therapeutic Association, 1910; and in *Monthly Cyclopedia*, December, 1910.

†"Diagnosis of Diseases of Cerebellar Apparatus," *Archives of Diagnosis*, January, 1910.

too complicated and demands too many psychopathological data to be described in this paper.

I have related only successes. Of course there are failures. If I have not cited them it is from no intention to misguide you by rose-tinted lenses. But it is high time that the prevailing "non possumus" which it is fashionable to cry regarding nervous disorders should be substituted by an attitude more rational because more true. So I have adduced facts to-night, merely to show the absurdity of the current pessimism. It is only the cry of the incompetent and of him who has observed only the work of the charlatan, whether pundit or quack. He who, however, thinks that cures can be effected by assurance without knowledge, vastly miscomprehends modern neurology and has reason for pessimism.

In these days of the howling from the mountain top, only the expert is competent to estimate the value of claims in the more recondite fields of human knowledge. As the Scotch say, "facts are chiels that winna ding." The facts that I have laid before you are pregnant with meaning for those who think. They show how greatly therapeutic power is augmented by the diagnostic assistance of a properly trained neurologist. I have taken it upon myself to present this thesis because I have been convinced it is hardly at all realized, and because we see so widely and deplore so much the vogue of the illicit medical practice which preys mainly upon the very patients who are most in need of neurological diagnosis. It is incumbent upon us to see that proper neurological training is given to the coming generation of medical men.* To do this, properly trained men, able to convey their knowledge clinically, must be appointed and given facilities in the hospitals, so that students and medical men can receive the benefit of the advance of knowledge and power. Only in this way can we combat the charlatan. Of the even larger work of neurological science in aiding social measures against disease, time will not allow me to speak. But even the laity are beginning to realize the need of special assistance in preventing mental unsoundness, in neurological inspection of children, in sociological measures for helping people who are peculiar, in the means of preventing crime and of reforming criminals. In all these, the science of psychopathology is indispensable; and every enlightened body of laymen would be the better for the assistance of a neurologist of deep learning and broad outlook. The pathogenetic interpretation of nervous symptoms due to artesiosclerosis is of great importance from a therapeutic point of view. Three such cases will be published this month, all successfully treated and now at work as a result of correct diagnosis. They were seen with Drs. Roy, Ballock, and Atkinson, respectively.

Blood-Pressure in Acute Nephritis of Children.—L. Gordon states that in the cases of acute nephritis occurring in young children the blood-pressure is raised and often raised to a marked degree.—*Archives of Pediatrics.*

Lactose in Infant Feeding.—H. P. Helmholz states that clinically excessive amounts of lactose may cause a chain of symptoms, namely, fever, diarrhea, leucocytosis, prostration, and death, which closely resemble the effects which follow the absorption of certain true bacterial toxins.—*Archives of Pediatrics.*

CARDIOSPASM IN INFANTS.*

By WM. GERRY MORGAN, M.D.,

WASHINGTON, D. C.

PROFESSOR OF GASTROENTEROLOGY, GEORGETOWN UNIVERSITY.

Until the last several years comparatively few cases of spasm of the cardia had been reported at any age and more cases have been noted in these first ten years of the present century than in the whole seventy-nine years of the last century since Parton's first description in 1821. The occurrence in children is still so rare as to be notable and in infants, to judge from the paucity of reports, it is of the rarest of conditions. It may be that in the future cardiospasm in children and infants will duplicate the history of congenital pylorospasm, which latter trouble has turned out to be a not so rare condition. Indeed it would not be surprising to learn that cardiospasm in children is more common than is supposed when we consider that besides an exciting cause there is a predisposition which is certainly present from birth in a considerable number of those who later develop the spasm. Fleiner even goes so far as to look upon the dilatation of the esophagus, which is practically always present above the location of the spasm, if the trouble is of any duration, whether as cause, result, or associated condition, as a congenital defect in the large majority of patients, believing that a latent state may exist for years. If this is so there must be an appreciable number in whom the condition does not remain latent, but gives symptoms of dilatation and spasm in infancy and childhood.

So rarely, however, is the diagnosis of cardiospasm with dilatation of the esophagus made in early life that I have thought it worth while to collect the few cases which have been so far reported in infancy and to add to them one of my own. I have been able to find records of but five cases occurring below two years of age, the first being that of Mèry[1] in 1906. This author seems to be particularly interested in the subject of spasms of the digestive canal in the young, having made two contributions on the subject; but among his cases is only this one in which the cardiac end of the stomach was affected. Mèry's patient was an infant of ten months when his observations were made, although some digestive symptoms had existed from birth. The diagnosis was confirmed by radiography. Adams[2] of Washington reported a case before the American Pediatric Society in 1908 which came under his notice at six months of age, although symptoms had existed almost from birth. His patient presented the typical symptoms which have been noted in all these cases, vomiting during or soon after feeding following marked efforts to swallow, the presence at times of glairy mucus with the food expelled, and periods of complete absence of symptoms for some days. Cold water would often precipitate an attack as well as long naps and exposure to drafts. Here as in other histories the parents are quoted as not being of a particularly nervous temperament. Autopsy of this baby showed the presence of an anatomic cause for the spasm in the form of a broken-down tuberculous gland with one diverticulum of the esophagus above and two below.

In 1909 La Fetra[3] of New York described the third case, which was really a spasmodic stricture of the esophagus, but as it differed from cardiospasm only in being two inches higher up we can

*Read before the American Gastroenterological Association, at Philadelphia, April 19, 1911.

with propriety include it with these cases. His patient was sixteen months of age at the time of examination, but there had been some vomiting and regurgitation since birth. One of the interesting points in this case is the fact that often after a few mouthfuls of food the baby would put her hand down her throat, and, as it were, pull out a handful of mucus and food, after which she could often finish the rest of the meal in apparent comfort. The diagnosis was substantiated by physical examination, an area of dullness appearing on the front of the chest from the first to the fourth interspaces after eating, and by radiography. At the time the report was made this little patient had improved wonderfully, first under the use of codein and fifteen drops of olive oil before feeding and later substituting tincture of belladonna for the codein. Only during the past two months has Bech[4] reported in the *Monatschrift für Kinderheilkunde* two cases of cardiospasm in infants in his practice. In one of the babies milk was introduced into the stomach by means of the tube at first, but the condition progressed in both until the cardia was impassible. Rectal feeding was necessary for a time and then after small doses of tincture of opium gradual feeding was started by mouth and recovery ensued.

This then concludes the number of previously reported cases as far as I have been able to ascertain and I will now briefly outline my own case. I herewith will give you the mother's report of her baby's illness exactly as she wrote it out for me because she was a graduate nurse and competent to judge of his condition.

January 27, 1911. Brentwood, Md. Raymond Krebs, aged nine months. Complaint: Persistent vomiting since third week of life. Family history: Maternal grandfather died at fifty-four of Bright's disease. Maternal grandmother living, aged sixty-two, in good health. Paternal grandparents living and in good health. Mother living, aged thirty-five, in good health. One brother living, age four years, in good health. No brothers or sisters dead. Previous history: Birth natural, labor not especially difficult; duration, about five hours. Breast-fed during first six months. Weight at birth, about eight pounds; at third month, about sixteen pounds, and at ninth month, seven and one-half pounds. Present illness: Baby was born April 4, 1910. Not a large child, but well developed, seemed perfectly healthy, only color a little too blue. Beginning at third week my child began vomiting a small amount of nourishment after each nursing; although attention was called to it I was assured it was nothing, as the child had probably nursed too fast or taken too much. Although vomiting occurred after each nursing, my child gained in weight until the third month, when it began to lose. During the first two months there seemed to be a great deal of gastric flatulence, which from the third month entirely ceased. My child also hiccoughed a great deal, when he would lie with his head retracted like a case of meningitis. While gently kneading his abdomen one day I noticed a rounded lump about the size of a walnut. I first noticed it on the right side and mistook it for hard fecal matter, although the child's bowels had moved on the previous day, and gave a soap enema with no result. The same day I gave another enema with the same result; that night I gave the child castor oil, after which the bowels moved well, and yet the hard lump remained on the right side. Several days later I noticed the lump on the left side and became worried and took my child for treatment, with negative results, the vomiting after each nursing with regurgitation through nostrils continuing. Seeing the child become emaciated I changed doctors. After giving second dose of Dr. K.'s medicine my child went into a state of coma for three-quarters of an hour; the face and body were icy cold and covered with profuse perspiration; on reaction he seemed very weak and from then on his decline was very rapid. I then refused further treatment from Dr. K., although he said he hoped to cure my child with a third dose of his medicine. He diagnosed the case as simple infantile marasmus. Then I took my child to see Dr. G., who told me the child's condition was marasmus; in other words the child was starving to death probably from malassimilation or other causes, and I requested an examination. The abdomen was examined while the infant was being fed and it was at this time that the abnormal movements of the abdomen were seen. The waves were so marked that they could easily be seen. The bulging produced seemed to travel across the belly, then slowly disappear. Dr. G. told me the child had a very rare condition which he called congenital hypertrophic stenosis of the pylorus. He advised taking my child from the breast and putting him on whey for a few days; in the meantime a brother of the child was taken ill with diphtheria and Dr. L. took charge of the case. He also advised feeding my child a very small quantity at each nursing. Still the vomiting continued and my child was losing weight very rapidly. A consultation between Dr. S., Dr. G., and Dr. L. took place, after which the child was given champagne, ten drops every half hour. Two level teaspoonfuls of a cereal proprietary food were added to ten ounces of whey, of which a dessertspoonful every fifteen minutes, day and night, was given. Sodium bromide powders (I do not recall what dose) were given every four hours. My child improved for about one week and then lapsed into his former condition. The urine was suppressed; his extremities and body had a very marked edema, and I was told by Dr. L. that there was no hope for my baby. He ordered me to give hotpacks and keep him wrapped up warm until free sweating was produced and then to rub him off with a warm dry towel and to keep him moderately warm. Although the vomiting continued the child seemed to improve for several days, when Dr. L. decided to take my baby to the Children's Hospital to have an *x*-ray of the stomach taken and in order that Dr. W. might examine him. Dr. W. decided not to *x*-ray my baby. After the trip to the hospital the baby became worse; the body at intervals was covered with small red spots; the extremities were blue and ice cold. The stools were green and slimy and contained undigested curds. The vomiting, apart from its persistency, was as though it was pumped up. Its large amount showed that the vomits represented more than one feeding, perhaps the accumulation of several feedings. The vomitus often came through the mouth and nostrils at the same time. The milk came up just as it was swallowed; it was never sour or curdled and often contained much slime. When the baby was laid down the milk ran out as from a bottle. The vomiting did not seem influenced by diet. In every case the improvement was only short lived, perhaps for a day or two or at most three weeks, when the vomiting would become more profuse and persistent and leave the child each time in a weaker condition. Every second day cold sweats occurred and the child would go into a state of coma and remain in that

condition from one to four hours. On November 18, 1910, my child went into a state of coma for seven and a half hours and on reaction was so feeble it could not move its upper or lower limbs or even turn the head. A consultation between Dr. L. and Dr. G. decided that the only and last chance was in an operation, which I opposed. Dr. C. was called in and after examination he declared the child to be suffering from infantile paralysis and spinal meningitis with an abscess forming on the left side of the head back of the ear. Dr. C. insisted that such was the disease and the child was given pure meat juice, one teaspoonful every four hours; cream and water, equal parts, one teaspoonful every four hours, and orange juice, one teaspoonful three times daily. The child improved for two weeks, when a complete collapse occurred, the worst which it had had, and Dr. S. was again called and after several days' treatment advised me that my child was in a very critical and hopeless condition. Then I had Dr. W. see my baby and he advised thyroid treatment and feeding by nutrient enema, which was already being done by Dr. S. My child did not respond to this treatment and in a dying condition I took him to Dr. W. G. M., who told me my child was dangerously ill with stoppage at the inlet of the stomach and that his only chance was by placing him in Garfield Hospital under the immediate care of one of the doctor's nurses. This we did and my baby never had another bad symptom and has steadily gained until it weighs seventeen pounds and is well to-day."

Before we had seen the baby the mother told us that the diagnosis was pylorospasm. I at once decided to attempt to dilate the pylorus by Einhorn's method, which th latter had used so successfully in a similar case. Dr. Clark telephoned Dr. Einhorn for the loan of his apparatus, which request was granted. When, however, we examined the little patient and got a detailed record of the case we readily recognized that the cardia and not the pylorus was in spasm. On further examination we proved that at that time probably very minute quantities, if indeed any fluid at all, were reaching the stomach, all being retained in a dilated esophagus. Attempts to pass even the smallest bougie failed. We then tried with a soft rubber catheter (No. 8 French), and after some manipulation it seemed to pass the point of obstruction and slip into the stomach. To determine this we ran some warm water through the tube and then blew a little air in by means of a small glass syringe while a stethoscope was held over the midepigastrium. A distinct bubbling was heard immediately under the stethoscope and a succussion splash was obtained when the epigastric region was palpated. The second swallowing sound was absent. The infant would at times eagerly take the food to the amount of from 100 c.c. to 150 c.c. and retain it until laid down, when the fluid would run out of its mouth and nose. At other times after taking from 60 c.c. to 90 c.c. he would cough and there would be heard a rattling sound in the chest. This preceded the regurgitation. When held in an upright position after feeding some dullness was to be noted on percussion over the lower end of the esophagus. There was no evidence of the presence of any of the liquid in the stomach.

The child was exceedingly emaciated, so that it was quite easy to examine its viscera. The position of the stomach was normal, but its capacity was greatly reduced, holding no more than 120 c.c. The pylorus, as the subsequent history proved, was functionating quite normally. When we first saw this baby his skin was in an unhealthy condition due to the repeated baths in oily medicaments. The catheter was left *in situ* and he was at once given through it 15 c.c. of warm milk every hour. He was given a warm soap and water bath and a gentle alcohol rub, was wrapped in soft linen and covered with a light woolen blanket, after which he immediately fell into a quiet sleep. Dr. Clark, my assistant, and Miss Donahue, my secretary, took turns in watching and caring for the little sufferer during the first twenty-four hours and to their efforts during this critical stage is largely due the successful outcome in this case. From the very first feeding the little patient thrived and seemed almost to appreciate the efforts being made in his behalf. The feeding tube was kept *in situ* continuously for four days and the amount of milk was gradually increased, but we were never able to give more than about 60 per cent. of the quantity normal to an infant of that age. At the end of the fourth day the tube was withdrawn after the last feeding at night and reintroduced on the following morning. Then we decided to take it out each night after the last feeding so that the child would have a more restful night. At the 3 A. M. feeding we allowed him to nurse the bottle and the milk seemed to pass into the stomach without difficulty as there was no regurgitation. The next feeding also was taken and retained in a natural manner. After the third feeding, however, the mother noticed the baby was restless, coughed from time to time, and finally some of the milk was regurgitated. Just before the next feeding the tube was put in and left in place for the remainder of that day's feedings. We continued to have the tube taken out at night and the child took nourishment the next day from the bottle until signs of spasm at the cardia came in evidence, when the tube was again put back. More and more of the feedings were taken in the natural way and by the end of the second week it was unnecessary to use the tube at all. During the second week, when it became necessary to put in a tube, we would have larger and larger catheters used so that a stretching effect would be produced. Thus little by little he was led back to the way of life normal for a youngster of his age.

As a matter of interest and to show what the human system, even in the case of a frail, half-starved infant, will endure, I append the mother's unclassified list of the foods and medicaments which were at one time or another administered to this infant, and the lesson therefrom is easily drawn: Milk, lime water, sugar of milk, albumin water, beef tea, meat juice, four different proprietary infant foods, cod liver oil, extract of beef, whey, pure cream, and water, orange juice, pineapple juice, beef, chicken, and lamb broths, champagne, whiskey, brandy, olive oil, white of egg, thyroid extract, camphor water, strychnine sulphate, sodium bromide, Fowler's solution, hypophosphites, morphine and other drugs too numerous to mention, given in prescriptions; and for massage, cod liver oil, olive oil, sweet oil, goose fat, and a mixture of whiskey, olive oil, and alcohol.

SURGICAL INDICATIONS IN LESIONS OF THE LARGE INTESTINE.

By RUSSELL S. FOWLER, M.D.,

BROOKLYN, NEW YORK.

In former years physicians were content to advise operation only in the face of acute or chronic intestinal obstruction, but as time wore on operations were occasionally performed for the relief of stasis of the intestinal contents without obstruction until at the present time many operations are being performed for the relief of mechanical constipation *per se*. It has seemed to the writer that it is possible that the pendulum may swing too far in this direction and that many inadvisable operations may be done, since at the present time so many men are doing surgical work who, with a few years' experience, are following the footsteps of men of many years' experience, supposedly duplicating their procedures, but in reality lacking the judgment of the more experienced men and who are not able to differentiate between those conditions in which operation is advisable and those in which it is not. The risk of operations involving the resection of the large intestine is such that experienced operators undertake the operation with misgiving and it is not uncommon for even surgeons of prolonged experience to meet with disaster. Unfortunately it is not always the disasters that are reported, and which are held up as examples to the younger generation of surgeons, but the brilliant results. It would, therefore, seem fitting that the indications for such intestinal operations be clearly defined. We will first consider briefly the commonly accepted indications for these operations.

In acute obstruction there can be no question as to the advisability of immediate operation. Of all cases of acute intestinal obstruction operated upon by me over two-thirds have come in the last stages of exhaustion from prolonged vomiting and absorption of intestinal contents. The cases which have been saved have been those which have come under observation in the first few hours of their obstruction. The fault in most of these cases lies in the inability of the physician to make an early diagnosis. The very term, intestinal obstruction, is misleading, for with an intestinal obstruction there may be a movement of the bowels following the initial pain, and if the obstruction be incomplete there may be several movements or gas may be passed from time to time. There is, however, one symptom of acute intestinal obstruction which is always present, and that is the initial pain, which is always severe and usually agonizing, and accompanied within a few hours by peristaltic movements above the site of the obstruction caused by an attempt on the part of the as yet unparalyzed bowel by normal peristaltic efforts to force its contents past the complete or partial occlusion. The average practitioner under such conditions gives the patient a hypodermic injection of morphine without, in most instances, considering the possibility of an intestinal obstruction. It is by so doing that the chance of making an early diagnosis is lost. Morphine quiets the attempts at peristalsis which are diagnostic, overcomes the shock, allays the pain, gives the patient a sense of well-being, and slows the pulse, the acceleration of which is of value in the determination of acute abdominal conditions. By so doing many valuable hours are lost and it is not until reverse peristalsis has begun that the physician is in a position to see that the patient has intestinal obstruction. There is a reason for every acute pain in the abdomen. The localization of the pain will often afford the only symptom for diagnosis in many acute intraabdominal lesions. This is particularly true in diseases of the appendix, gall bladder, and pancreas, diseases which need operation at some time and are better operated at the onset of the disease. These diseases are those which are commonly confused with acute complete or incomplete obstruction. The physician should also disabuse his mind of the idea that in acute complete obstruction the bowels do not move. There may be one movement or two movements, an enema may be effectual in bringing away some gas, for the contents of the intestine below the obstruction are still able to be moved downward by normal peristaltic movements of the intestine which, in the first few hours of the attack, are not yet weakened. In many incomplete obstructions peristaltic efforts are sufficient to force large amounts of fecal matter past the site of the incomplete obstruction, but the passage of the fecal current at this point will be accompanied by pain, and if morphine is administered this pain may be so hidden as to be lost sight of. It is hardly necessary to call attention to the necessity of making a thorough examination of the patient for causes of abdominal pain outside of abdominal conditions such as tabes, pneumonia, and diaphragmatic pleurisy.

In chronic obstructions, which are usually acute obstructions by the time they come to the surgeon, it would seem that the practitioner should arrive at a diagnosis earlier than he does, and I think the reason for his failure to do so is for the most part due to not making a thorough examination of the patient. Many cases come to me which have been treated for months for hemorrhoids in which a digital examination reveals an inoperable carcinoma of the rectum. In these cases the practitioner has never made a digital examination, but has prescribed ointments and enemata. It is reasonable to suppose that had these cases been carefully examined when they first presented symptoms of rectal distress the disease would not have been so far advanced as to preclude the possibility of removal. Many cases of malignant disease of the large intestine come to me with a history of gradually increasing constipation. An abdominal examination reveals a tumor and it is reasonable to suppose in these cases also that when the constipation was becoming more marked had an *x*-ray plate been made the disease would have been recognized before it had attained an inoperable stage. These two examples should be a lesson to all. It should teach us not to rely upon the textbook pictures of carcinoma of the rectum or of carcinoma of the large intestine in any of its course, but to investigate by all the means in our power the first interference with the function of the rectum or of the large intestine, and fortunately in both of these parts of the anatomy an early diagnosis of malignant disease is easily made, either digitally in the case of the rectum or by the *x*-ray in the case of the large intestine. Not only in these diseases, but in all dieases at the present time we should investigate the apparently trifling errors in function as they occur. They are the precursors in many instances of serious disease. That errors must occur from time to time is unquestionable, but I have yet to see a too early diagnosis in these diseases. To summarize, in the cases of acute complete or incomplete and the chronic cases of intestinal obstruction,

the former may be diagnosed by the pain and attempts of peristalsis early in the course of the lesion, the latter by investigating the at first apparently trifling functional disturbance, the increasing constipation.

As regards intestinal operations in cases which do not present either acute complete, incomplete, or chronic obstruction, that is, the class which present evidence of constipation, either alone or with more or less indefinite pains, with perhaps occasional attacks of sharp but not agonizing pain, or with pulling pains in various parts of the abdomen during the process of large intestinal digestion or during defecation, or with recurrent attacks of not very severe colic, or constipation associated with marked changes in the well being of the patient, this may be said: In the first place, in the course of several thousand laparotomies for other disease I have observed a large number of cases of ptosis of the various parts of the colon and sigmoid. Operation has only been done on these conditions if there were symptoms which seemed directly referable to these displacements. I am not speaking now of Glenard's disease, but of ptosis of some part of the large intestine alone. Many of these cases have not presented any functional disturbance of the large intestine whatever; therefore it is pertinent to say here that given a case in a female patient, for instance, with retroverted uterus, with symptoms of interference with the function of menstruation, and with vague, indefinite sense of discomfort in the left iliac region and in which a radiograph shows a prolapse of the transverse colon into the pelvis with some prolapse of the sigmoid, but with no symptoms of interference with the function of the large intestine, that it would not be good surgery, however brilliant the final result might be, to subject such a patient to an intestinal resection or even suspension of the colon in addition to the necessary operation upon the uterus and adnexa. What I wish to bring out is this, that no mattetr how displaced the large intestine, or for that matter any of the viscera, may be, providing these organs functionate properly there is no reason for operation upon them. Should, however, these displacements be due to tumor or to adhesions from former operations, then the tumor or adhesions should be attacked. But in the case of ptosis *per se* great caution must be used in advising operation, especially operations involving much risk, as for example resection and anastomosis. The condition of ptosis is so common and so frequently observed in connection with other abdominal lesions at operation that we must exercise great care in differentiating the symptoms of the main lesion from the symptoms of the ptosis. Particularly is this true since radiography has taken such strides in aiding us in the diagnosis of vague abdominal conditions, for the most extreme conditions of ptosis will be shown by the radiograph, and if one is not careful one may place upon the condition of ptosis the burden of bearing all the responsibility for the abdominal symptoms. Therefore in every case presenting ptosis it is best to start with the knowledge that ptosis is common and may not present symptoms. Also we must remember that the risk of major operative interference such as resection or anastamosis is much more in the large intestine than in the small, therefore the risk must be very carefully weighed in comparison with the degree of discomfort suffered before a decision is made. If the pain is severe or frequent or at times disabling, or if there is marked interference with the well being of the patient, either through malnutrition or nervous symptoms aside from all vague nagging abdominal discomfort, there is no question but what the risk may be undertaken. When there is any doubt as to the advisability of the operation mechanical measures such as support, massage, hydrotherapy and allied methods of treatment should be first undertaken

There is a class of patients who present symptoms comprising intermittent attacks of constipation without pain or with slight pain referred either to the epigastrium or about the umbilicus. These patients may have occasional nausea and vomiting. The symptoms may be confused with chronic appendicitis. These are cases of enterospasm of the large or small intestine. In the case of the large intestine the *x*-ray will substantiate the diagnosis by showing in a series of plates made during the attacks the contracted portion of the intestine, but even if this were not verified by the *x*-ray such symptoms as above stated are sufficient for an exploratory laparotomy, the advantage of the radiograph examination being that at least in the case of the large intestine the site of the enterospasm can be definitely located and resection at this point undertaken, for it is true that these enterospasms are not constant, so that unless located by the *x*-ray definitely they may easily be overlooked in the course of the exploratory laparotomy.

To summarize the indications for intestinal operations for constipation, we may say that no matter what mechanical displacement is present, operation should only be done when the function of the organ is interfered with either constantly or intermittently to such an extent as to be a source of so much discomfort as to negative the risk of a major intestinal operation.

It goes without saying that we would like to cure patients who present symptoms of abdominal distress or general symptoms from prolapse of the colon with interference with its function. At the present time the cure of such cases must be operative in most cases. Suspensions are inadequate and unreliable in many cases; anastomosis is also a makeshift and uncertain. There remains for consideration resection. It is the cure *par excellence*, but the risk is too great to take except in cases with marked symptoms, as stated above. Logically it follows that we must seek for some method of resection of the large intestine which will not only be efficient, but which will be safe. The danger resides in the length of time necessary to resect, in the possibility of stricture, and in leakage. The time consumed is to a great extent dependent upon the accurate planning of the operation. Less time is usually lost in the actual steps of the operation than in arriving at a decision as to what is the best procedure to follow. The danger of stricture may be largely overcome by proper technique. Leakage is due in part to bad technique. Leakage may occur at the mesenteric border or at other points. In the latter event it is usually due to lack of care in providing for an efficient blood supply. In resecting the large intestine there should be free bleeding from the cut intestinal wall. If there is not one cannot be sure of the blood supply. The bleeding points can be individually tied with fine catgut. The mesenteric angle should be first approximated with one or more mattress sutures, taking in all the layers of the gut and carefully inverting the mucous membrane at this point. For the remainder of the

anastomosis two layers of continuous sutures are best, one of chromic gut made pliable by immersion in 30 per cent. alcohol to approximate all layers but the serosa, beginning at the mesenteric suture and ending there, being tied first to the first end which has been left long; the other, a Lembert stitch of paraffin silk or Pagenstecher approximating the serous surfaces and necessarily dipping into the subserous tissues in order to grip well, begins at, secures the leaves of both mesenteries, and after surrounding the gut again pierces both leaves of the mesentery and ends there, being tied to the first end, which has been left long for this purpose. Both sutures should be interrupted at every sixth or seventh stitch, by a back stitch, so that puckering or a purse-string effect, which would tend to form a subsequent stricture, does not occur. The cut in the mesentery should be approximated and any available tab of fatty tissue made use of to further protect the line of suture. If one is in doubt as to its security the anastomosis may be surrounded by a sling of gutta-percha tissue, which is led out of the abdominal wound, as advised by Mayo. This serves to support the anastomosis and acts as a telltale in case of leakage.

301 DeKalb Avenue.

A PRELIMINARY REPORT ON THE EFFECT OF SALVARSAN ON SYPHILITIC AND METASYPHILITIC AFFECTIONS OF THE EYE AND UPON THE APPARENTLY HEALTHY EYES OF SYPHILITICS.

By M. ROSENBAUM, M.D.,

NEW YORK.

OPHTHALMOLOGIST GERMAN POLIKINIK; ASSISTANT ATTENDING OPHTHALMOLOGIST PEOPLE'S HOSPITAL.

It has been my opportunity lately through the courtesy of Drs. A. L. Wolbarst and V. C. Pedersen to study the results of salvarsan on the different lesions of the eye that are produced by syphilis. While observing the effect on various eye manifestations, I have also had the opportunity of observing its action on the apparently healthy eyes of syphilitics in all stages, who showed other lesions of lues than those of the eye. I shall give a résumé of the history of twenty-two cases, so far as they relate to the eye affections and the observations made before and after injection of salvarsan while the patients were at the People's Hospital of New York City.

Let us first consider the various lesions of the eye that may be the result of a luetic infection. We know that syhpilis may attack any and every part of the eye, though the uveal tract, owing to its vascularity, is the most often attacked, and especially so during the secondary stage. Iritis, cyclitis, choroiditis, and hyalitis are the most common during that stage. The frequency of iritis in syphilis is variously estimated by different authorities; some place it as low as 4/10 of 1 per cent., and others as high as 5 per cent. In my service at the German Polyclinic during the last five years I have found it to be about 3 per cent. of all cases treated. A. Cantonnet considers iritis the most frequent manifestation of lues. Cyclitis and choroiditis are the next in frequency and the former more so than the latter. Choroiditis when accompanied with the fine dust-like opacities of the vitreous is pathognomonic of syphilis. I have not seen a single case where a history of lues was not obtainable. Syphilis may attack the optic nerve directly or indirectly through a lesion in the brain; the sphincter of the iris and ciliary muscle may be likewise affected. Optic atrophy is often the first sign of tabes, and may precede it by many months and even years. Erb has proved that tabes dorsalis in 90 per cent. of all cases is due to syphilis. We see, therefore, that lues may attack any part of the eye or its nerve, and the damage may be such as to be irreparable. The treatment of all such cases heretofore has been a thorough antisyphilitic one, and in the early stages, *i.e.* before destructive damage was done, it has been quite effective in a majority of cases. With the introduction of salvarsan, a new field has been opened for the treatment of syphilitic affections of the eye. I propose to divide the twenty-two cases into various divisions, according to the anatomical portion of the eye attacked.

Case I.—Tabes dorsalis, optic atrophy (partial). Dr. Wolbarst's patient. J. N., male, aged thirty-six, had gastric crises, and marked ataxia. Denies venereal history of any kind. First symptom of illness appeared six years ago, in the form of gastric pains, accompanied by occasional attacks of vomiting. Was treated for gastric disease until six months ago, when the diagnosis of tabes dorsalis was made by Dr. George J. Saylin of Buffalo, N. Y. These symptoms were then present: Absence of knee jerk, marked ataxic gait, Romberg symptom, Argyll Robertson pupil, gastric crises with vomiting, shooting and lightning pains in the legs. Optic atrophy, loss of flesh and strength. Wassermann reaction strongly positive. Urine negative as to sugar and albumin. Was put under treatment consisting of injections of salicylate of mercury and arsenic. Strychnine internally for the optic atrophy. October 21, 1910. Marked ataxia, necessitating use of two canes and other support. Stumbles in the dark. All diagnostic symptoms of tabes marked and unmistakable. Eyes examined by Dr. E. Gruening: "O. D. 3/100; O. S. 3/200. Both fields concentrically limited. Absolute color blindness. Optic atrophy." Examination of viscera, heart, lungs, and kidneys, normal. Pulse 96, not very strong. Wassermann reaction strongly positive. At the earnest solicitation of the patient, and on his assuming all liability as to the outcome, he was admitted to the People's Hospital October 24, 1910, for treatment. On that date I examined the patient at the request of Dr. Wolbarst and found the same lesions as were found by Dr. Gruening. He was injected with 0.5 gram salvarsan, Alt method. October 28, 1910, I reexamined the patient and found that vision was not as good as before. O. D., fingers at five feet; O. S., fingers at three feet. Atrophy somewhat advanced. November 2, 1910, he left the hospital, feeling much better, except for his sight. December 3, 1910, a communication from his physician, Dr. Saylin, to Dr. Wolbarst states: "Despite progressiveness of optic atrophy, gait and general condition show improvement. Patient is inherently hysteroneurasthenic, yet, after careful observation, I can say that his condition has improved markedly, except his vision." December 13, 1910, a communication from Dr. Saylin to Dr. Wolbarst states as follows: "Wassermann reaction, December 10, taken by Dr. A. A. Thibaudeau, is positive, but less strongly so than formerly." As regards this case we can

say that although all the other signs of tabes were much improved, nevertheless, salvarsan could not stop the progress of the optic atrophy.

Case II.—Complete optic atrophy. H. G., age twenty-six (Dr. Wolbarst's patient), was admitted November 14, 1910. He gave a history of having been infected in 1903. Two years ago became blind suddenly on the right eye and six months later on the left. One year ago the right side of body was paralyzed. Control of the rectum and bladder was lost, but under treatment recovered. On examination I found both nerves completely atrophied with no perception of light. He received 0.6 gram salvarsan intramuscularly, and on November 22 I reexamined him, found no change for better or worse, although the patient said that he saw flashes of light. On November 26 I examined him again, but found no more change than the last time. The flashes were still present. On December 19, at his own request, he was again admitted and reinjected. I examined him on December 21 and 23 and found no appreciable change, subjective or objective.

Case III.—Syphilitic iritis. W. S., male, aged twenty-three (Dr. Wolbarst's patient). Admitted to the hospital on October 17, 1910, suffering with a cutaneous syphilide, and a severe syphilitic iritis of the left eye, with two distinct nodules at the pupilary margin of the iris. The iritis dated back since September 5. The fundus also showed a very distinct chorioretinitis and exudate into the vitreous. Initial lesion on the penis in May, 1910. He was injected on October 17, 1910, with 0.5 gram salvarsan and atropine was ordered. Vision, O. D., 12/12; O. S., 12/100. October 24, 1910, circumcorneal injection diminished, one nodule disappeared; the iris was gradually returning to a healthy condition. October 28, 1910, iris normal, no sign of iritis except for a single synechia. Vitreous retina and choroid clear. Vision, R., 12/12; L. 12/50. October 30, 1910, iris normal, vision about same as at last examination. Patient left the hospital perfectly well.

Case IV.—Cerebral syphilis. A. A., aged twenty-nine (Dr. Wolbarst's patient). Admitted November 2, 1910. Primary affection in 1905. Was treated irregularly with mercurial injection. Eighteen months ago suffered an attack of right hemiplegia while under the influence of alcohol. On examination the left eye shows some deposits on Descemet's membrane from previous iritis. Retinæ and optic nerves normal. He was injected November 3, 1910, with 0.5 gram of salvarsan. November 5, 1910, he was reexamined; no material change in the iris, vitreous, choroid, retina, or nerve. November 9 and 13, no material change. November 14 he was discharged, practically well.

Case V.—Tabes. E. M., aged thirty, male (Dr. Wolbarst's patient), admitted November 2, 1910. History: Does not know when he was infected. Has all the symptoms of tabes; walks with two canes. Ataxia marked. Injected November 3, 1910, with 0.6 gram of salvarsan. November 3, 1910, O. D. normal; O. S. iridoplegia. All the other muscles of the eye not affected. This was probably due to a gumma in the region of the crus. November 5, reexamined; pupil slightly contracted. November 14 the pupil reacts fairly to light. November 15, discharged. Result, marked improvement.

Case VI.—Secondary syphilis. J. S., aged twenty-four, male (Dr. Wolbarst's patient). Admitted to the hospital October 23, 1910. History of an infection five months ago. Many mucous patches in the mouth and throat. Injected October 23, 1910, 0.6 gram salvarsan. Examined October 23, 1910; no lesions of the fundi, except myopia. Vision, O. D. 12/70; O. S. 12/100. October 28, 1910, reexamined; no apparent change in the fundi. October 30, 1910, no change; discharged.

Case VII.—L. F., primary and secondary syphilis; aged 25, male (Dr. Wolbarst's patient). Admitted to the hospital November 14, 1910. History of infection six weeks ago. Injected November 14, 1910, 0.6 gram salvarsan. Examined November 14, 1910. O. D., normal, O. S., physiological excavation of the optic nerve. November 18, no change in the fundi. November 22, reexamined; no material change in the fundi. November 24, no change, patient discharged.

Case VIII.—Supposed case of gumma of femur. A. A., age forty, male (Dr. V. C. Pedersen's patient). History: Began to have pain in one leg in February, 1909; pain situated in the right thigh, above the knee. A few days later the leg from the knee to the groin became swollen and remained so for some time, when an abscess formed at the knee, which was opened and healed. At the time of the operation, which was on September 9, 1909, the patient states, a half cupfull of bloody water came from the wound. On September 19, 1910, the wound was opened the second time and healed, but there still remained an enlargement of the lower end of the femur. The patient was injected on a supposition that it was a gumma of the bone. Admitted November 17, 1910. Injected November 18 with 0.5 gram salvarsan. Examined November 17. Both eyes normal. Vision, O. U. 20/20. Reexamined December 3, 1910. O. U. 20/20. Complaint of a dull pain in the left eye. No objective signs in any portion of the eye.

Case IX.—Tertiary syphilis, A. C., male, age twenty-seven (patient of Dr. Wolbarst). Portuguese by birth. Initial lesion six years ago. The patient gives a history of all primary and secondary lesions. There is a perforation of the hard palate. Examined November 22, 1910. Vision, O. U. 20/15. Fundi, normal. Injected November 23 with 0.5 gram salvarsan. Reexamined December 3, fundi showed no change. December 5, 1910, no change; discharged.

Case X.—Tabes dorsalis; M. G. C., age twenty-seven, male (Dr. Wolbarst's patient). Admitted November 22, 1910. History: Initial lesion eighteen years ago. He gave a history of a secondary lesion and was treated irregularly for two years. At present the pupils do not react to light or accommodation. Knee jerks, absent; Romberg sign, present. Injected November 22, 1910, with 0.5 gram salvarsan. Examined November 22; vision, O. D. 20/20. Fundi, normal. November 27, fundi normal. December 3, same condition as on previous examination. Discharged, symptoms distinctly improved. December 23, 1910, a communication from Dr. E. E. Foster, New Bedford, Mass., states: "O. D. 6/6, with + 2; exophoria 14°; O. S. 6/5 with—2. Right hypophoria ½°. Discs pale. No atrophy. Field of vision normal."

Case XI.—Secondary syphilis; F. G., age twenty-seven, male (Dr. Wolbarst's patient). Admitted November 22, 1910. History: Initial lesion nine months ago. Three months later developed a rash over the body, which disappeared under mercurial injections. Now the roseolea has returned, while under treatment. Injected November 22 with 0.5

gram salvarsan. Examined November 22. Eyes, normal. Reexamined November 27 and 30, and December 1; no appreciable change. Patient discharged.

Case XII.—Tertiary syphilis. J. K., age fifty-six, male (Dr. Wolbarst's patient). Admitted November 26, 1910. History: Initial lesion eleven years ago. Eighteen months after suspected intercourse developed a sore throat and was told it was due to lues. He was treated irregularly since that time. At present he shows a few mucous patches at the angle of the mouth. Leukoplakia of the tongue. Examined November 27. Vision, O. D. 15/70, astigmatism. Fundi, normal. Injected November 27, 0.5 gram of salvarsan. Reexamined November 30. Fundi show no material change. Reexamined on December 3, 7, and 9. Same condition as on previous examination. Patient discharged. Result, no bad effect.

Case XIII.—H. W., age nineteen, male (Dr. Pedersen's patient). Previous history negative. Family history negative. Gonorrhea four years ago. A clear history of secondary syphilis. Treated with twenty-six mercurial injections. Iodide by mouth for fourteen months. At present he has a feeling of malaise and syphilitic laryngitis. Wassermann, positive. Admitted November 27, 1910. Injected November 29. Examined November 28. Fundi normal; blood-vessels show a distinct arteriosclerosis. December 3, reexamined; no material change in the fundi or in the walls of the blood-vessels. December 9, 12, and 19, same conditions as on previous examinations. Result, no change.

Case XIV.—O. A. F., age twenty-six, male (Dr. Pedersen's patient). History: Chancre on the lip two years ago, followed by secondary symptoms. Admitted November 28, 1910. Eyes examined November 28. Fundi normal. Injected November 29 with 0.5 gram salvarsan. Reexamined December 3. No change in the fundi. Patient discharged.

Case XV.—J. H., age thirty-eight, male (Dr. Pedersen's patient). Perforation of the palate. History: Initial lesion four years ago, followed by a rash on the body two months later, with sore throat and headaches. Two swellings appeared on the forehead three years later, which disappeared under treatment. At present he has a perforation of the hard palate and a broken down gumma of the forehead. Examined December 5, 1910. Vision, O. U. 20/15. Fundi normal. Injected December 5, 0.5 gram salvarsan. Reexamined December 7 and 10. Fundi and vision the same as on previous examination. Patient discharged.

Case XVI.—Gumma of the tongue. S. R., female, age twenty-one (Dr. Pedersen's patient). History: Three months ago she noticed a little blister on the anterior third of the tongue and she began to use mouth washes. The blister was also cauterized. Admitted November 30, 1910. Examined November 30. Found both eyes to be normal. Vision, O. D. 15/15; O. S. 15/70; astigmatism. Injected November 30 with 0.5 gram salvarsan Reexamined December 5 and 11; no material change in the fundi. Patient discharged. Result, no bad effect.

Case XVII.—B. S., female, age thirty-seven (Dr. Wolbarst's patient). Perforation of the palate: destruction of nasal septum. History of initial lesion could not be obtained, but seventeen months ago she noticed pain in the knee and pain in the nose. She was told that the nasal septum is rotting away and pieces actually came out. At present she has a perforation of the hard palate, a partial destruction of the nasal septum, and the nose is full of hard crusts. The eyes, on examination, showed that the fundi were normal; vision, O. D. 20/20, O. S. 20/50. Admitted December 11, 1910. Injected December 12 with 0.5 gram salvarsan. Reexamined December 15, 21, and 24; no material change in the fundi.

Case XVIII.—E. C. H., male, age twenty-nine (Dr. Wolbarst's patient). Admitted December 12, 1910. History: He was infected nine years ago from a chancre on the upper lip and received local treatment. He then went to Hot Springs and was treated for two months. Present history: He has a copper colored rash over the left lumbar region, covered by crusts and small ulcerations. The tip of the nose is thickened, enlarged, and the skin purplish red in color. The eyes on examination, December 12, 1910, were both normal. Vision, O. U. 6/6. Injected December 12 with 0.6 gram salvarsan. Reexamined December 15, 19, and 21. No material change in the fundi or in vision.

Case XIX.—M. K., male, nineteen years (Dr. Wolbarst's patient). Admitted December 29, 1910. He was infected one year ago and was treated at the City Hospital for a chancre. At the time he had a rash on his body, a sore throat, no alopecia and no headaches. On examination we found he had a perforation of the hard palate; he was pale, anemic, and showed he was suffering from a constitutional disease. Wassermann test was positive. The eyes, on examination, showed no abnormality; fundi were normal. Vision, O. D. 6/15, O. S. 6/30. Corrected by glasses. Reexamined January 2 and 5, 1911. No material change in the fundi. Patient discharged.

Case XX.—B. S., age thirty-nine, male (Dr. Wolbarst's patient). This was a case of chancre in the meatus and Dr. Wolbarst demonstrated the spirochete. I examined his eyes on December 19, 1910, and found them to be healthy, except for myopia, with — 6.00 Sph., 20/20. Admitted to the hospital December 20 and received 0.5 gram salvarsan on the same day. I reexamined him on December 21, 26, and 30, and January 2, 1911, and found no change in fundi. Patient discharged.

Case XXI.—E. D., female, age twenty-three (Dr. V. C. Pedersen's patient). She gave a history of having been infected from her brother. Six months ago she had a sore throat and pain in the bones, and headache. Three months ago an eruption appeared on the body, palms of the hands, and soles of the feet. Present history: She has a typical copper colored rash all over the body and gummatous ulcers over both tibias. Admitted December 19, 1910. Injected December 20 with 0.5 gram salvarsan. I examined her eyes December 20 and found both fundi normal. Vision, O. U. 20/20. Some physiological cupping. I reexamined her December 26, 1910, January 2, 4, and 8, 1911, and have on no occasion found any abnormality of the fundi. She was discharged January 10, 1911, much improved in the other lesions and no deleterious effect on the eyes.

Case XXII.—M. G., male, age thirty-three (Dr. Pedersen's patient). Admitted December 21, 1910. History: Two years ago he noticed a sore on his penis, followed by a rash on his body, alopecia, and headache. Present history: The patient shows a paralysis of the right side of the face, the tongue deviates to the right. The eyes show no abnormality of the fundi. He was injected on December

24 with 0.6 gram of salvarsan. Reexamined on December 30 and found the paralysis was improving. The fundi showed no change and vision was normal. I saw him again on January 2 and found no change. January 3, patient discharged.

From these twenty-two cases we can see that in Cases I and II, one of complete atrophy of the optic nerve and the other a far advanced case, salvarsan neither cured one nor materially improved the other. In Cases III and IV we can see the good effect on iritis within one or two days after injection. Case V shows what a marvelous effect this arsenical preparation has on gummatous deposits. The remaining seventeen cases prove conclusively that salvarsan has not the slightest deleterious effect on the healthy eyes of syphilitics and is far superior to atoxyl, which may produce atrophy of the optic nerve. Ehrlich contraindicates salvarsan in optic neuritis and beginning optic atrophy.

Although we have not had an opportunity of seeing any case with optic neuritis where it has been tried, nevertheless, we have seen it in cases with advanced optic atrophy and no deleterious immediate effect was noticed. Fehr (*Deutsche medizinische Wochenschrift*, Vol. 41, No. 10) does not believe it is contraindicated in beginning optic neuritis and beginning optic atrophy. Another question may arise, and that is, can salvarsan produce an iritis or a neurochorioretinitis? We have not seen such an occurrence in the twenty-two cases here mentioned. Fisher reports such an occurrence, but it seems more probable that the iritis mentioned would probably have occurred, owing perhaps to the fact that the injection was insufficient to destroy all the spirochetes in the body, and a few having lodged in the eye, a very favorable nidus, started a new growth which manifested itself in the iritis mentioned. In view of the fact that all the cases are so recent, it is still too early to speak of permanent results. However, the immediate results can be formulated thus:

1. The preparation is very effective in secondary and tertiary manifestations of the uveal tract.
2. It causes no appreciable subjective or objective symptoms on the healthy eyes of syphilitics.
3. No appreciable improvement has been noticed in parasyphilitics and in cases of optic atrophy.

School Sanitation.—The following health program has been recommended by the Nebraska Association of School Principals and Superintendents: (1) Compulsory installation in school houses of ventilating heating plants. (2) Compulsory cleaning and disinfecting of school houses at least twice a year. (3) Compulsory medical inspection of school children. (4) Compulsory submission of all school house plans to the state architect for approval. (5) Compulsory medical inspection of all school teachers.—*Bulletin of the Russell Sage Foundation.*

The Complications of Adenoid Operations.—G. Hicquet and A. Fallos give the results of observations on adenoid operations, which are done by them to the number of 600 per year at the hospitals and in private practice. A precaution to be observed is always to operate when there is no rise of temperature, such as may occur in an acute adenoiditis. Nor should we operate during an epidemic of measles, diphtheria, or scarlet fever. In young girls we should avoid the menstrual period. Hemophilia, tuberculosis, albuminuria, and diabetes should contraindicate operation. In children under two years of age narcosis is not absolutely necessary. From fifteen years up local anesthesia can be used. Between two and fifteen years a general anesthestic should be used. The Beckman curette is preferred, used with gentleness lest the surrounding structures be injured. Fragments left behind may be a cause of hemorrhage Primary or secondary hemorrhage is the most frequent complication. Primary hemorrhage lasts but a short time. A marked hemorrhage may result from an anomaly of the arterioles of the mucosa, cutting the tubercle of the atlas, or fibroid condition of the adenoid, preventing contraction of the vessels. Secondary hemorrhage comes at the end of about a week, on the fall of the eschar. Nervous troubles sometimes occur after the operation. Infections are not rare; a diffuse catarrh of the pharynx is common; it is due to mouth breathing after the operation. Abscess, lacunar tonsillitis, and otitis also may occur. The adenoid child is a chronically infected being, and exacerbations may occur at any time. If the patient keeps to the house after the operation infection is less likely to occur. The author recommends that the child be kept in bed two days, fed on liquid, unirritating foods, given a purgative the day after the operation; and that it should go out of doors at the end of a week. With these precautions the operation is simple and benign. —*La Policlinique.*

Evolution of Language in Reference to Phonetic Teaching and Medicine.—Vincenzo Cozzolino says that language is a system of articulate voice used to convey the internal processes of thought. The first cry of the infant simply shows the excitability of the respiratory centers in the medulla. It is not a conscious expression of pain. The infant is incomplete; up to the sixth month the medulla alone functionates reflexly. Sight and hearing are both incomplete. After some weeks sounds are made that are the beginning of articulation imitation, and conscious reproduction. Automatic repetition follows. The teacher should understand the development of speech in the child in order to understand the various faults of hearing and language. The child begins to notice not the articulation of those about him, but the accent, character, intensity, and modulation of the voice. Between the fifteenth and eighteenth months the child begins its real language by simple exercises of vocalization. The first syllables are exclamatory, like the language of echolalia and onomatopeia. The perception of sound and sight are closely connected. At this moment of coordination between the peripheral expression and activity of the center of ideation it is that if the child becomes deaf there is complete mutism, since the sense of auditive memory is rudimentary The progressive coordination of language runs parallel with the acquirement of voluntary muscular movements. Autology guides the child in the construction of phrases. The hearing, normal infant repeats involuntarily the words heard; then fits the image seen to the word heard. Finally he gets an emotional idea of the things seen. Retardation of language does not necessarily denote retarded mentality, nor vice versa. For the perfect development of speech and writing we must have three factors, perfect cerebral function, good auricular and visual function, and normal motility of the vocal organs and those devoted to writing.—*Giornale Internazionale delle Scienze Mediche.*

THE UNDEVELOPED FIELD IN LIFE INSURANCE.

THE educational campaign recently inaugurated by life insurance companies for the purpose of diminishing disease and increasing longevity represents only the beginning of a movement that bids fair to attain extraordinary momentum. Efforts have thus far been directed solely with the view of influencing the individual policy holders, who are quick to perceive that their own interests and those of the company are identical. But the problem of conserving health and prolonging life is one that can not be solved solely by the efforts of each individual so far as his own particular mode of life is concerned; it requires the concerted action of entire communities in the improvement of those manifold conditions that are comprised under the term "public health." In order to make their campaign an effective one, the insurance companies must enlarge its scope by directing their efforts, not merely toward the individual, but toward the collective community.

This is the keynote of a report submitted at the bi-monthly meeting of the Association of Life Insurance Presidents, at New York, June 9, 1911, by Mr. Hiram J. Messenger, actuary of the Travelers Insurance Company. As the result of a trip undertaken for the purpose of studying the sanitary condition of southern cities he has arrived at the following conclusions: There was evidence found practically everywhere that there had been a most wonderful improvement in the general sanitary conditions during the past ten or twenty years, and there was the possibility of still further progress in the next ten years. The cities of the South in proportion to their means are spending, as a rule, as much money in public health work as the cities of the North. Cities in the same section of the country and in close proximity present a great variation in the degree of public sanitation. There is a generally prevailing impression even in cities with poor sanitary conditions, that their own sanitation compares favorably with that of other cities, and it is this ignorance of what is being done in other cities that stands in the way of further progress. Most of the cities have a fairly good water supply, but not a single city which was visited had any systematic method of examining the water in its wells. The water system is always more extensive than the sewer system, large sections of the city in almost every case not being sewered. From a quarter to more than half of the inhabitants live in houses that have no sewer connections. Most of the cities visited had unsatisfactory methods of garbage disposal. There is an activity greater than formerly in the enforcement of ordinances for inspection of milk and other foods, but in this direction there is still room for much improvement. Bacteriology in connection with city sanitary work is comparatively new.

In bringing the results of these investigations before the Association of Life Insurance Presidents, the speaker alluded to the fact that the success or failure of a life insurance company, assuming honest and intelligent management, depends upon three things—the expense rate, the interest rate, and the mortality rate. These factors are of approximately equal importance. But adequate efforts have not yet been made to lower the mortality rate; past efforts in this direction have been practically confined to the careful initial selection of risks. The regular life insurance companies in the United States, not including the industrial business, are paying about $150,000,000 a year for death claims, or about $12 per thousand dollars of insurance in force. If the rate of loss was reduced from $12 to $11 per thousand of insurance, the companies would gain in reduced claims about $12,000,000 every year. To secure a favorable mortality these companies are paying about $6,000 a year for medical examinations and inspection reports before the risk is accepted, and practically nothing for this purpose after the policy is issued. The average policy is for about $2,500 and the average premium about $100. If a company postpones the death of one of its policyholders for one year it means, besides the inestimable advantage to the life prolonged, that other policyholders receive one more premium ($100) and have another year's use of the amount of the claim ($100)—making a total of $200 additional receipts as the result of postponing the insured's death for one year.

In order that the insurance companies may wield a powerful influence in improving sanitary conditions throughout the country, Mr. Messenger suggests that there be established in each city an organization of influential men interested in the sanitary welfare of the city. "In every city of fifty thousand inhabitants in this country it is possible to find among the managers, the leading agents, the medical examiners, and the legal and financial representatives of the insurance companies fifteen to twenty men of standing, of influence, and of a high average standard of intelligence. From these men, together with two or three of the leading health officials and a few other men of prominence interested in such questions, could be formed an organization, which if directed and given to understand that it would be thoroughly supported by the organized life insurance companies of the country, could exert an influence in bringing about better sanitary conditions—which would mean the saving of millions of dollars to the life insurance policyholders of the country."

The feasibility of this plan is unquestioned. Its main requirement is united action on the part of all life insurance companies, which, in sinking their individual company interests in an effort to improve the public health, are at the same time contributing in no small measure to their own financial advantage.

THE ATTACK ON DR. WILEY.

The enemies of Dr. Wiley, some though by no means all of whom might be called by the great denunciator "undesirable citizens," have seized upon what they allege to be an illegality in his employment of an expert analyst of drugs as a ground for demanding his dismissal. To the ordinary and unprejudiced observer the action for which he is denounced would seem to be rather a commendable cutting of red tape than a crime, but, as the Attorney-General says he has "merited condign punishment," it may be technically more serious than it appears to be. We cannot believe, however, that the President will dismiss an efficient public servant because of a slight irregularity in winning over to the service of the country an expert of the high standing of Dr. Rusby. Rather should he be commended for securing the employment of so good a man on such favorable terms for the Government. A mild reprimand would be a sufficiently "condign punishment" for such a breaking of the rules. If, however, as has been asserted, he has also been insubordinate, having disobeyed the orders of Secretary Wilson, the case may assume another aspect.

The reason for Dr. Wiley's unpopularity is evident. He belongs unfortunately to a class of men, of whom there are many in more or less public life to-day, who are honest and earnest in their fight for what they believe to be the right, but whose utility as reformers is impaired by their temperaments. They are opinionated, convinced of their own infallibility, uncompromising to the last degree, and unable to see that those who differ from them may also be honest in their convictions and possibly right. Dr. Wiley has done invaluable service in his fight for pure food, but was mistaken in the benzoate of soda controversy. As a result of a series of crude experiments he fortified himself in his preconceived opinion that small quantities of this drug used in the preservation of food were prejudicial to health, and this conclusion was not shaken by the results of careful experiments by a board of experts, composed of men his equals in honesty and, without disparagement it may be said, his superiors as physiological chemists. The opinions of men such as the late Christian Herter, Chittenden, Long, and Remsen are not to be lightly brushed aside simply because they are at variance with the belief of Wiley or because they support the contention of certain food manufacturers. The question is not whether these manufacturers can use refuse material in the making of their products —the pure food and drug law can or ought to prevent that—but whether the addition of a minute quantity of benzoate of soda to good material to prevent its spoiling is harmful. If Dr. Wiley had had the courage to admit his error and had made his fight on the main question of the purity of material used in the manufacture of food products, the opposition against him to-day would be confined to a handful of dishonest men and the country would be on his side in his brave fight for pure food. As it is, many of his opponents are men at one with him in the effort to preserve the health of the consumer of condiments, but convinced that his uncompromising attitude is an injury to the cause.

We hope the President will not yield to the importunities of those who seek Dr. Wiley's dismissal, for in spite of his faults of temperament he has done and is doing a good work, and we also hope, almost against hope, that this trial will show him the necessity of compromise—not with evil doers, but with honest men who are striving for the same end as he, but who recognize the fact that obstinacy is not firmness and that reform is not to be effected through insubordination and stubborn adherence to error.

EXPERIMENTAL MEASLES IN THE MONKEY.

In 1898 Josias reported certain positive results in the experimental inoculation of monkeys with measles, while seven years later Hektoen produced measles in two human beings by means of inoculations of blood drawn from a measles case at an early stage of the disease. Grünbaum in the *British Medical Journal*, April 9, 1904, reported various attempts at infecting two chimpanzees with the result in the opinion of the experimenter that these attempts were not only without effect but that they "may even have conferred immunity rather than conveyed infection." John F. Anderson, Director of the Hygienic Laboratory, Washington, D. C., and Passed Assistant Surgeon Joseph Goldberger have recently been experimenting with monkeys to put the question of their receptivity to the infection of measles to further test.

Describing their results in *Public Health Reports*, June 9 and 16, 1911, these observers state that their first experiment was performed on June 8, 1910, with some blood obtained from a case of measles at the Willard Parker Hospital, New York. Two monkeys were inoculated; in each a slight rise in temperature was noted on the eleventh day, the significance of which was not appreciated at the time. A second attempt was made with similar results. On April 28 of this year a third attempt was made, three rhesus monkeys being inoculated. Once more, as regards temperature reaction, results were obtained essentially like those of former experiments. In the case of one monkey an eruption and other symptoms resembling those of measles occurred. On May 16 last a fourth attempt was made; two monkeys were inoculated and at the same time the monkey which had exhibited symptoms on the former occasion was reinoculated with a view to testing his immunity and obtaining light on the previous reaction. Ten days after inoculation one monkey showed distinct symptoms but was accidentally killed before further observations could be made. The second

monkey developed a well marked febrile reaction eight days after inoculation. The temperature remained elevated for four days, then dropped abruptly to its normal range. Ten days after inoculation this animal developed a well-marked maculopapular eruption which in two days became generalized. In seven days this had died out. Desquamation was noticed only on the scalp and temple. The monkey which had been reinoculated showed no reaction whatever. Blood aspired from the heart of the two animals which showed reaction was used for the inoculation of four fresh rhesus monkeys. All showed reaction to a greater or less extent. Anderson and Goldberger believe that they are justified in concluding that they have demonstrated the susceptibility of the rhesus monkey to inoculation with the blood of human measles drawn from the general circulation early in the eruptive stage.

Continuing their investigations, these observers report in the *Journal of the American Medical Association*, July 8, 1911, that there is a period of infectivity of the blood beginning at least just before and continuing for about twenty-four hours after the first appearance of the exanthem. At the end of this period the infectivity of the blood appears very greatly reduced, and diminishes progressively. This definitely limited period of infectivity for monkeys apparently accounts for the opinion generally held that the monkey is not susceptible to measles.

Pregnancy After Nephrectomy.

In accordance with the modern conception of the toxemia of pregnancy, the deprivation of a woman's kidney might, in theory at least, favor the development of the graver accidents of this autotoxic state. For while the latter is no longer held to be due at all to renal insufficiency, it is, doubtless, able to set up the so called pregnancy kidney with a resulting vicious circle in which the amount of parenchyma in the remaining kidney, even with compensatory hypertrophy, might hardly be sufficient for compensatory activity. Hence all cases of pregnancy following nephrectomy possess an unusual degree of interest and by their very nature should be able, with a sufficient amount of material, to furnish some documents of value, not less important if negative. Haberern reports a case of negative significance in the *Deutsche medizinsche Wochenschrift* of June 1. He also refers to four previous recorded cases in which the nephrectomized parturients did not suffer in the least during or after gestation. This is the more remarkable because the hypertrophic remaining kidney undoubtedly possesses an increased tendency to stasis, nephritis, and uremia. That such a result is far from inevitable, however, appears from a recorded series of fifty-nine patients controlled for six years after nephrectomy in whom no untoward effects had developed. Much must depend upon the conditions before operation and for which operation was performed. Surgeons who have performed nephrectomy in similar cases have doubtless always warned against further pregnancies. Should a nephrectomized pregnant woman develop suspicious renal symptoms Haberern insists that the pregnancy should, of course, be terminated forthwith.

Are There Special Trophic Nerves?

Verworn laid down the principle that every nerve is a trophic nerve to the tissues in which it is distributed. This may be understood to refer only to central impulses propagated along efferent fibers, or may be extended to include impulses which begin at the periphery and are propagated along the reflex arc as centrifugal impulses. The theory that impulses may be propagated in either direction along sensory nerve fibers is, to say the least, superfluous for the explanation of special trophic impulses. At a recent meeting of the Gesellschaft für Natur und Heilkunde zu Dresden (*Münchener medizinische Wochenschrift*, June 13) Haenel considers the problem of the existence or nonexistence of special trophic nerve fibers. Concerning the coincidence of intact sensibility and trophic disturbances following injury he states that absence of sensory disturbance by no means implies fully intact sensory nerves. The pathological alterations may be of so intimate a nature that mere sense perception is not interfered with, yet these minimal alterations may modify the nutrition of the tissues over which the nerve presides through disturbance of the spinal ganglionic reflex, as manifested by vasomotor disorders in the affected tissues. The assumption of special trophic nerves is so far superfluous in that purely local processes in the tissues together with vasomotor disorganization of reflex mechanism are sufficient to account for so called trophic disturbances. Until we know more about the functions of the sympathetic it will be well to refrain from theorizing as to trophic nerves.

Nitrogen Retention in Nephritis and Uremia.

As is of course well known, retention of nitrogenous substances in nephritis with resulting autointoxication, is not the simple mechanical problem which at first suggests itself. At the recent meeting of the German Congress for Internal Medicine, Hohlweg covered this subject and his paper provoked an extensive discussion (*Münchener medizinische Wochenschrift*, May 9). In healthy subjects the residual nitrogen varies roughly from 40 to 60 milligrams daily, in nephritis from 60 to 100 mg. The percentage of individual constituents is unaltered, urea being virtually constant at 60 per cent. If uremic poisoning is superadded to nephritis the residual nitrogen is not increased in such cases as recover. But in incurable cases the retention increases until before death it may reach between 300 and 400 milligrams. Nitrogen retention, aside from these cases, bears no definite relationship to uremia. In discussion Volhard stated that he would distinguish between uremic symptoms and uremia. Thus eclampsia is not accompanied by abnormal nitrogen retention, while in true uremia the retention may vary from 100 to 400 mg. Reiss was also an adherent of this dualistic view. Gerhardt isolated from uremia the syndrome due to edema of the brain. He and others also called attention to the beneficent effects of venesection and lumbar puncture on this syndrome. Lüthje would not restrict the term uremia to conditions in which focal cerebral symptoms are in evidence. He referred to cases of so-called chronic uremia, characterized by persistent headache and motor and psychic inquietude, and implied that such cases were often wrongly diagnosed as cerebral sclerosis. Brugsch has studied nitrogen retention in uremia and nephritis, and has found that urea constitutes 80 per cent. of the retained nitrogenous substances.

News of the Week.

Typhoid Epidemic.—Following an appeal for aid from the officials of Little Rock, Ark., Dr. W. H. Frost of the Public Health and Marine-Hospital Service has left Washington for that city. One hundred and twenty-one cases of typhoid fever were reported up to July 15. It is said that the regular city water supply is not contaminated.

Plague in China.—During the first two weeks of July, twenty-five deaths from bubonic plague were reported in Amoy. There were also eight deaths from smallpox and three from cholera.

Plague in Morocco.—Bubonic plague has been reported in several parts of Morocco.

Infant Deaths in New York.—In spite of the intense heat during the first part of July, there was a notable decrease in the number of deaths of infants under one year of age, the number being only 706 from July 1 to 15, or 300 less than during the same period of 1910. Of these, 148 deaths were ascribed to diarrheal diseases, as compared to 363 in 1910. During the first six months of 1910 there was a total of 8,043 deaths from all causes among infants under one year of age.

The Cholera Situation.—Eight deaths in or about New York from cholera have been reported. The first two were those of an immigrant man and woman who had been released from Quarantine, and another was that of an employee on Hoffman Island, who is supposed to have contracted the disease from a cholera carrier. The cholera patients were sent to Swinburne Island from the steamship *Perugia,* which arrived from Naples on July 14, while the *Moltke,* which arrived on July 5 from the same port, brought eight cases of the disease. Of these passengers, three have since died. It is reported that 2,300 deaths from cholera have occurred in Palermo alone since last May, and cases are also said to have been found in Tuscany and in Marseilles and Toulon.

A Medical Special to Los Angeles.—A very enjoyable feature for many of the Eastern physicians attending the meeting of the American Medical Association was the excursion to the Coast and back on a special train organized, under the direction of Dr. Wisner R. Townsend of New York City, by the McCann's Tours Agency. The train was composed of six compartment sleepers, with observation, dining, café, and baggage cars. It left New York on the evening of June 19 and returned the morning of July 15, having in the meantime visited the Grand Canyon of Arizona, Redlands, Riverside, Los Angeles, the Yosemite, San Francisco, the big tree grove of Santa Cruz, Del Monte, Paso Robles, Santa Barbara, Salt Lake City, and Colorado Springs. The distance traveled in the train was 8,049 miles, and that covered by automobiles, stages, and carriages nearly 100 more. There were over one hundred persons, physicians and their families, in the party. Unlike some conducted tours, this one was acknowledged by all to be a perfect success. It was well arranged and scrupulously carried out without a hitch or disagreeable incident from start to finish.

Milk Inspection.—The New York City Department of Health has detailed, during the present summer, some of its milk inspectors to examine the temperature of the milk as it is received at night at the thirteen points where milk comes into the city. The results are reported as very satisfactory, the average temperature of eighty-eight specimens examined being 49° F. On two of the hottest days during the recent tropical weather, 618 specimens of milk were examined, and of these only seventy-eight were found to be above 50° F. In addition to this work, inspectors are also detailed to inspect the milk as it is being delivered from wagons to retail stores, and it has been found that the milkmen are exercising much greater care in handling the milk and in using ice to cool it while in transit. A similar investigation of the small stores where milk is sold has showed the same improvement.

Vital Statistics.—During the month of May there was a grand total of 12,384 deaths in New York State, according to the bulletin of the State Department of Health. Of this number, 955 deaths were due to epidemic diseases, 1,272 to tuberculosis, and 1,272 to other diseases of the respiratory organs, including pneumonia.

Hookworm in North Carolina.—The campaign against hookworm in North Carolina is progressing steadily. During the last twelve months the number of cases of the disease reported as undergoing treatment increased from 3,250 to 21,000, and the number of persons examined for the disease at the State Laboratory of Hygiene from 500 to 23,312. Of these 7,276, or about 31 per cent., showed infection with the hookworm, while 2,543 showed infection with other intestinal parasites.

Saccharin in Food.—The United States Department of Agriculture has recently modified paragraph 3 of Food Inspection Decision No. 135, to read as follows: "The Secretary of Agriculture, therefore, will regard as adulterated under the food and drugs act foods containing saccharin which, on and after January 1, 1912, are manufactured or offered for sale in the District of Columbia or the Territories, or shipped in interstate or foreign commerce, or offered for importation into the United States."

Summer Babies' Hospital for Philadelphia.—On the initiative of a number of physicians, in conjunction with the Director of Public Health, a hospital has been opened on the outskirts of Philadelphia for the care of infants of less than two years of age, especially suffering from gastro-intestinal diseases of the summer season. A sufficient sum of money has been raised for the purpose and a competent medical staff has been appointed. The new institution will occupy, rent free, the country branch of the Children's Hospital.

Chair of Eugenics.—Dr. Carl Pearson has been appointed the first professor of eugenics in the London University, filling the chair recently endowed by Sir Francis Galton.

Board of Inebriety.—As required by law, Mayor Gaynor of New York recently announced the selection of two physicians to serve on the Board of Inebriety created by an act of the Legislature last spring. Dr. William Browning of Brooklyn and Dr. John Dorning of New York have received the appointments. The board in addition consists of two clergymen and a business man. It has authority to establish a hospital and an industrial colony to which persons suffering from habitual drunkenness may be committed.

Gifts to Charities.—By the will of the late Mr. Abraham Abrahams of Brooklyn the Jewish Hospital of that city receives a bequest of $50,000, the income of which is to be applied to the maintenance and support of the institution.

The Presbyterian Hospital of New York re-

ceives a bequest of $100,000 under the will of the late Adele A. Dortic, the money to be used to build and maintain a home for convalescents. The New York Infirmary for Women and Children also receives a bequest of $3,000.

The International Congress on Tuberculosis.—A press despatch from Rome announces that this congress, which was to have been held in that city in September, has been postponed on account of the presence of cholera in Italy.

Safeguarding Hospitals.—The New York City Board of Aldermen recently, at the request of the Commissioner of Charities, ordered an issue of special revenue bonds in the amount of $200,133, to provide funds for a suitable fire protection system in the city hospitals and buildings under the jurisdiction of the Department of Charities.

American Laryngological, Rhinological, and Otological Society.—At the seventeenth annual meeting of this Society, held in Atlantic City, June 1-3, the following officers were elected for the ensuing year: *President,* G. Hudson-Makuen, Philadelphia; *Vice-Presidents, Chairman of the Eastern Section,* Theodore Corwin, Newark, N. J.; *Chairman of the Middle Section,* John A. Thompson, Cincinnati; *Chairman of the Western Section,* Thomas J. Gallagher, Denver; *Chairman of the Southern Section,* Otto Joachim, New Orleans; *Secretary,* Thomas J. Harris, New York; *Treasurer,* Ewing W. Day, Pittsburg.

Wisconsin State Medical Society.—At the annual meeting of the society, held in Waukesha recently, the following officers were elected for the ensuing year: *Prsident,* Dr. J. M. Dodd of Ashland; *Vice-Presidents,* Dr. T. J. Redelings of Marinette, Dr. C. A. Armstrong of Boscobel, and Dr. Hoyt E. Dearholt of Milwaukee; *Secretary,* Dr. Charles S. Sheldon of Madison; *Assistant Secretary,* Dr. L. Rock Sleyster of Waupun; *Treasurer,* Dr. Sidney S. Hall of Ripon. The next meeting of the society will be held in Wausau.

Northern Tri-State Medical Association.—This society, whose members are scattered over Ohio, Indiana, and Michigan, held a meeting at Toledo, Ohio, on June 6. The election of officers resulted as follows: *President,* Dr. C. N. Smith of Toledo; *Vice-President,* Dr. Victor C. Vaughan of Ann Arbor; *Secretary,* Dr. George W. Spohn of Elkhart; *Treasurer,* Dr. J. A. Weitz of Montpelier.

Des Moines Valley Medical Society.—At the fortieth annual meeting of the society held in Ottumwa on June 15 the following officers were elected for the ensuing year: *President,* Dr. A. O. Williams of Ottumwa; *Vice-presidents,* Dr. W. W. Eastburn of Sigourney and Dr. S. K. Davis of Libertyville;; *Secretary-Treasurer,* Dr. P. W. Bowles of Ottumwa.

Public Cups Barred.—Under an act passed recently by the New Jersey State Legislature, the State Board of Health announces that after July 4 public drinking cups are prohibited in the following places throughout the State: All parks, streets, highways, hotels, schools, halls, theaters, and other entertainment resorts, public libraries, all penal, philanthropic, and other State and municipal institutions, railroad and trolley cars and stations, boats and waiting rooms, all vehicles used for carrying passengers for a consideration, all places to which the public have the right of access with or without compensation, whether maintained by private or public authority.

Death of Centenarian.—After celebrating her 108th birthday on last New Year's Day, Mrs. Lachia Williams of Lansing, Mich., died suddenly at her home on June 27.

For Cancer Hospital.—At the commencement exercises of Harvard University held on June 28 announcement was made that during the past year $150,000 had been collected for the Cancer Hospital.

Charitable Bequests.—By the will of the late Mr. Isaac Stern of New York, Mount Sinai Hospital receives a bequest of $1,000.

Dr. Sarah Tew Mayo of New Orleans has been given the loving cup awarded each year by the New Orleans *Daily Picayune* to the citizen who has rendered the most signal public service of the year, as decided by a commission of disinterested persons. This is the first time that the cup has been awarded to a member of the medical profession. Dr. Mayo is a graduate of the Woman's Medical College of Philadelphia, and has been active in work among the sick poor of New Orleans.

Dr. John Shrady, formerly of New York, announces his removal to 38 Pleasant street, Stamford, Connecticut.

Obituary Notes.—Dr. Sewell Matheson of Brooklyn, N. Y., a graduate of the Long Island College Hospital in 1895, a member of the New York State and Kings County Medical Societies, the Brooklyn Gynecological Society, the Brooklyn Pathological Society, and the Alumni of the Norwegian and Lying-In Hospitals, assistant gynecologist to Williamsburg Hospital, and visiting surgeon to the Methodist Episcopal Hospital, died at his home of typhoid fever on July 9, aged 41 years.

Dr. Edwin A. Lewis, 64 years old, a retired surgeon, died July 18 at his home in Englewood, N. J., of paralysis after a long illness. He was born at Naugatuck, Conn., and was graduated at Yale University in 1870 and at the Bellevue Hospital Medical School in 1873. Dr. Lewis practised in Brooklyn for twenty years, retiring in 1895. At the time of the building of the Brooklyn Bridge and for several years afterward he was bridge surgeon, and he had served two years in Brooklyn as a police surgeon and two years as a surgeon for the Fire Department. He was for years a visiting surgeon at the Brooklyn, Long Island, St. Catherine's, and Flatbush hospitals, and Professor of Anatomy at the Long Island College Hospital medical school. He was for ten years surgeon of the Twenty-third Regiment.

Dr. William J. Walsh, Coroner of San Francisco, Cal., a graduate of the Medical Department of the University of California in 1902, and a member of the California State and San Francisco County Medical Societies, died at his home on June 23, at the age of 32 years, from injuries sustained in an automobile accident two weeks before.

Dr. J. Elvin Courtney of Denver, Col., a graduate of the Medical College of Virginia, Richmond, in 1883, and a member of the American Medical Association and of the Colorado State and Denver County Medical Societies, formerly assistant physician at the Matteawan, N. Y., State Hospital for the Insane, died at his home of pleurisy, on June 23, aged 51 years.

Dr. J. H. Aleshire of Plainfield, Ill., a graduate of the College of Physicians and Surgeons of Keokuk, Ill., in 1877, died at his home on June 25, aged 61 years.

Dr. John Quincy Adams McCollester of Waltham, Mass., a graduate of Jefferson Medical

College, Philadelphia, in 1856, a member of the Massachusetts State and Middlesex County Medical Societies, a veteran of the Civil War, and a member of the Board of Trustees of Norwich University, died at his home, on June 23, aged 80 years.

Dr. Charles A. Trexler of Knoxville, Pa., a graduate of Jefferson Medical College, Philadelphia, in 1887, died at his home on June 30 from injuries received in an automobile accident.

Dr. Crown Torrence of Charleston, S. C., a graduate of the Medical Department of the University of Nashville, Tenn., in 1898, and a member of the State and County Medical Societies, died at his home on July 1, aged 35 years.

Dr. David Franklin Buck of New York, a graduate of the Medical Department of New York University in 1891, died at his home on July 12.

Dr. Ralph E. Gallinger of Concord, N. H., a graduate of the Dartmouth Medical School, Hanover, in 1896, and a member of the American Medical Association and the New Hampshire State and Merrimack County Medical Societies, and physician to the New Hampshire State Prison, was killed in an automobile accident on July 12, aged 39 years.

Dr. Henry Rock Connor of New York, a graduate of the Bellevue Hospital Medical College in 1894, a member of the Alumni of the French Hospital, and assistant visiting physician to the French Hospital, died at his home on July 7, aged 54 years.

Dr. John F. Sprink of Council Bluffs, Iowa, a graduate of the John A. Creighton Medical College, Omaha, Neb., assistant of histology in the same, and president of the staff of the Mercy Hospital, Council Bluffs, and a member of the Iowa State, Missouri Valley, Pottawattamie County, and Council Bluffs Medical Societies, died suddenly at his home on July 2, aged 33 years.

Dr. George W. Taylor of Nolan, W. Va., a graduate of the Barnes Medical College of St. Louis in 1901, died at his home on July 1.

Dr. Weston H. Rice of Oakland, Cal., a graduate of the Medical Department of the University of Vermont in 1905, and local surgeon for the Southern Pacific Railroad, was killed in an automobile accident on June 27.

Dr. Robert Foster Andrews of Gardner, Mass., a graduate of the Dartmouth Medical School, Hanover, N. H., in 1857, and a member of the Massachusetts State and Worcester County Medical Societies, died after a short illness, on July 10, aged 75 years.

Correspondence.

WHAT IS REST FOR THE PROFESSIONAL MAN?

To the Editor of the Medical Record:

Sir:—In the issue of the Medical Record for May 27 Dr. Francis of Montclair, N. J., very ably advocates the value of rest as a preventive of premature age and break-down of the busy professional man. It is fitting that this subject is offered for discussion, when it is generally observed and often commented upon that the successful doctor, scientist, lawyer, and corporation magnate are so frequently cut off in a career which should in natural expectation have extended ten to twenty years longer, and, still more significant, that those in the profession who should know best how to conserve their natural forces furnish the more numerous victims of premature decay. In the Medical Record of April 15 editorial comment is made upon the untimely death of Kroenlein, and the premature mortality generally among Continental medical men of high attainment. To have gained pre-eminence in Continental universities, where the competition of minds is keen, implies a high order of mental endowment, the genius for intense application and industry, and prolonged years of constant struggle and effort. What is true of the Continent is true of America, and what is true of medical men is likewise true in all other fields of effort, where to come to the front requires years of strife and application—and more than ever is this true since the enormous expansion of every branch of learning in the later decades.

The usual method of such men, as they become more and more absorbed in their work, more driven by the duties and care their work engenders, more wearied and jaded, is to regard ideal rest as the periodical withdrawal from their labor, or the substitution of a new and diverting line of intellectual employment, and in this way soothe tired nerves and sharpen their faculties for renewed effort in the chosen field. But is this rest? While it does recuperate the fagged nervous system, what of those parts of the organism which carry on the functions of physical life—the respiratory, vascular, muscular, and excretory? During many years of intense mental application these have been totally ignored and allowed to carry on their work with the least possible cost of time and effort, and at length, when our subject should yet be in the very flower of manly strength and vigor, he has become distasteful of physical exertion, languid of movement, easily wearied, and tempted to indulge further inaction by the plea of needed rest.

The needed rest, which should have been from early manhood, is best expressed by *hard work*—or at least what the woodchopper or digger would call hard work. No man engaged in absorbing intellectual pursuits should be satisfied with less than two hours daily of vigorous exercise in the fresh open air—the equivalent of a seven-mile walk. This is the toll he must pay if he may have the right to expect his career to extend to the commonly accepted scriptural limit. The price of old age is the regular and vigorous use throughout life of those organs whose functions are essential to its continuance. Whenever doctors learn to prescribe and practise the doctrine of hard work as the professional man's rest, for at least two hours of every twenty-four, beginning in early manhood and continuing through 365 days of every year, ceasing only when the decrepitude of age compels, then will there not be found among medical and other professional men that deadly blight of career at 50 or 60 years by arteriosclerosis, fatty heart, apoplexy and paralysis, degenerate kidney, and tuberculosis. Acute disease also will get fewer victims. Sanguine youth may treat with contempt so simple a remedy for far-distant ills, but the time is pretty sure to come to him who acts upon this contempt when his heart will falter at the demands he shall make upon it, or his radial artery roll hard under his touch, his breath come short on quickening his pace or climbing a declivity, and he will then know it is too late to hope for benefit from any remedy, and how the best fifteen or twenty years to convey to posterity the rich harvest of his mental industry are beyond his grasp.

It is a pleasing fiction in which doctors indulge as to the exhausting toil their profession demands—and yet what degree of physical exertion does the average busy medical man get? He receives his pa-

tients during his morning office hours, rides to those he must visit, again receives in his office, and again rides to other calls, to return to his home for what reading or social intercourse he can get before retiring. Many men live this life in which the real physical exertion of an entire day could easily be condensed within a half-hour's active exercise; never an opportunity to make the cheek glow with quickened circulation, or the chest heave in deep inspiration—instead only sluggish indolence, lethargy of muscle, heart, and lungs. Before the entrance upon the last quarter of the race of life, is it any wonder unused organs falter or fail entirely to do their work? No claim to originality or even novelty is made for these observations. The principles involved are well understood, but how sadly ignored by our best medical talent!

J. Harvey Hill, M.D.

Hotel Altamont, Baltimore, Md.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

MEDICAL INSPECTION OF SCHOOLS—NATIONAL INSURANCE BILL, MEDICAL OPPOSITION, DEPUTATIONS, DEMANDS FOR DELAY, THREAT OF GAG IN PARLIAMENT—MEDICAL RESEARCHES AUTHORIZED BY LOCAL GOVERNMENT BOARD—OBITUARY.

London, June 30, 1911.

Dr. Addison, M. P., on Tuesday introduced to the Education Board a deputation on the medical inspection of schools. He said the method of the County Council was defective and inadequate. Sir V. Horsley said this deputation asked the Board to compel the London County Council to carry out the inspection according to the code of the department and the act of 1907. He declared the maladministration of the Council was a scandal and he regretted the Board had sanctioned its continuance instead of the school clinic system. The hospital scheme should be put an end to.

The president of the Board (Mr. Runciman) replied that they had not given an approval to the L. C. C.'s scheme during the last two years. He quite understood the fear of the finance committee when the deputation said 100 clinics were needed, but he saw no reason why medical treatment should be shirked as an extra burden on the ratepayers. They pressed on the Council the need of inspection. Consequently the inspectors were raised from 52 to 70 and more recently to 100 doctors. Improvement had begun and he hoped it would continue.

The passage of the national insurance bill is not so smooth as was anticipatel. Mr. Lloyd George is receiving deputations almost daily from different interests affected by it and people are amazed to see how his plausibility overcomes their objections at the time, though they afterwards feel dissatisfied. The interests of the medical profession and the friendly societies are, however, so completely opposed that he has not yet effected a compromise. The county councils and the municipal corporations at an interview on Tuesday received certain explanations which were supposed to meet their difficulties respecting the proposed "health committees" and amendments were promised restricting the activities of these new bodies. But on reflection the objections have been merely explained away in words —not removed in fact.

Some of the Chambers of Commerce, Chambers of Agriculture and other bodies are pressing amendments on the attention of the Chancellor but the medical aspects of the scheme claim precedence. The British Medical Association has worked the question astutely enough and carried out a canvass of the profession, making a special appeal to non-members to join as well as to sign the undertaking to refuse to take part in the work except on the terms I have already mentioned. The appeal has been successful, hundreds of new members being enclosed in the net. If all who have supported the declaration remain firm we shall see something like a strike against Mr. Lloyd George's terms and he will be obliged to increase the rate of payment or submit to complete failure; for it is obvious that he cannot create qualified practitioners in a hurry. Something of this kind, I hear, took place in Germany and the government had to submit. Our Chancellor received a second deputation of doctors on Wednesday, when the wage limit was the chief point discussed. The bill proposes £160 a year, which is obviously absurd. To pretend that a man earning more than £3 a week is a fit candidate for the benefit of club practice is contrary to the whole history of this semi-charitable provision. If this system, which the working classes have carried out for themselves with unquestioned success and ability, is to be displaced by a compulsory state insurance to which employers as well as workmen are required to contribute the premiums, surely the medical men are entitled to be paid a remunerative price for their services.

Yesterday Mr. Lloyd George had another interview with the medical men who met him the previous day for the B. M. A. The discussion was less cordial and it seems doubtful what good may come of it. The Chancellor would not agree to reduce the wage limit but laid the opposition to such a concession on the House of Commons. He seemed to think the clerk class might not like it also but was not much concerned for them. Not many of them are voters. Some other points he said he would leave to the unfettered judgment of the House of Commons.

That House was taken by surprise, the reporters say, when last night Mr. Lloyd George announced in his quiet manner that the government proposes to move a resolution on Wednesday to allocate time for the various stages of the bill. Thus debate is to be crushed if possible. The opposition is, of course, indignant and a number of the government's supporters condemn the proposal. A radical group, in fact, at once held a meeting which resolved that the guillotine ought not to be applied to a measure which was allowed a second reading without a division but has not yet got into committee. It is said that the cabinet was rushed by the Chancellor and would not object to discovering some way of reconsidering this matter, as it is obvious the bill is not so vote-catching as was expected. To-day's *Lancet* says that the profession will be exposed under the insurance bill to even greater risk than is indicated by the apparent intention to underpay practitioners who may cooperate in the scheme. The risk is that the status of the profession may be hopelessly lowered and the supply of candidates for qualification decline. It would be a disaster if this should occur. "Medical opposition to the bill is unanimous and the many and various grounds for the professional attitude require time for their exposition."

A meeting of medical graduates of the London University has been called for Wednesday next to consider the bill.

The Society of Apothecaries has added its voice to that of the other corporations and demands delay, fearing that injustice will be done to its licentiates if the bill be pushed through Parliament this session.

Many meetings, medical and non-medical, as well as journals, support the demand for delay and Mr. Lloyd George has himself said that he spent three years in preparing the measure with all the aid the Treasury and the Board of Trade could give him, and yet he wants to rush it through Parliament in as many months!

The following researches to be paid for by the annual Parliamentary grant have been arranged for by the Local Government Board: 1. Causes of premature arterial degeneration, by Dr. Andrewes. 2. Causes of death in measles, Dr. Thursfield. 3. Number and kind of fleas found on rats, Professor Quick, F. R. S. 4. Prevalence and characteristics of microorganisms known as non-lactose fermenters in alimentary canal of infants, by Dr. C. J. Lewis in continuation of his former investigation into this subject. 5. A similar research into this subject, by Dr. D. M. Alexander. 6. Non-lactose fermenters in flies in normal surroundings and in those associated with epidemic diarrhea, Dr. Graham Smith. 7. Anaërobic bacteria in the alimentary canal of infants, Dr. Bainbridge. 8. The possibility of pathogenic organisms being taken up by the larva and subsequently distributed by the fly, Dr. Graham Smith.

Sir George Plunkett O'Farrell died on the 22nd, aged 66. He took M.B., T. C. D. in 1869 and proceeded to the M.D. in 1875. He had held various appointments in Ireland, as inspector of reformatory and industrial schools, inspector in lunacy, commissioner of control, inspector of the Local Government Board and medical commissioner of prisons.

Surgeon W. Forrest Archibald, M.B., Ed. R. N. died suddenly on the 22nd, aged 29. He joined the service in 1905.

Dr. Ashby G. Osborn of Dover died on the 23rd, in his eighty-third year.

Dr. Alex. M. Smith of Glasgow died on the 20th, aged 77. He was superintendent of medical missions in the Bridgton and Cowcaddens districts.

THE CANADIAN MEDICAL ASSOCIATION.

(From Our Special Correspondent.)

MONTREAL, June 28, 1911.

IN the section on medicine there was held a symposium on acute poliomyelitis. Dr. C. A. Hodgetts, medical adviser to the Commission of Conservation of Canada, contributed a paper dealing with the statistics of the disease in that country. In order to find out all the facts possible concerning the mortality and morbidity statistics of the disease in Canada, the Commission of Conservation sent out in November last a circular letter of inquiry with blank return forms to each Canadian physician. Eight thousand letters were sent out and replies were received from 316 medical practitioners and thus the histories of 656 cases were reported which occurred between November 1, 1909, and October 31, 1910. These 656 cases were divided by provinces in the following manner: Ontario, 354; Quebec, 157; British Columbia, 48; Alberta, 27; Manitoba, 17; New Brunswick, 12; Saskatchewan, 6; Nova Scotia, 6, and Prince Edward Island, 1. As to sex incidence, of 528 cases 293 were males and 235 females. Of the total number where age was stated, 554, only 23 were under one year of age. Of the remaining 531, 341 or 64 per cent. were between the ages of one and five years. A comparison of the age incidence in three epidemics of the disease in Canada, Boston, and New York is somewhat remarkable. Under the age of twelve months the disease occurred in from 7 to 8 per cent. of the cases in the Boston and New York epidemics, as against only 4 per cent. in the Canadian epidemic. In the New York epidemic 90 per cent. of the cases were under five years of age; while in Boston 71 per cent. and in Canada only 65 per cent. were of this age. Of those over twenty years of age, there were 43 cases in Canada as against 31 in Boston and but 3 in New York. It was noted that in the New York outbreak over 99 per cent. of the cases were under twenty years of age. As to the seasonal occurrences in Canada, while the speaker stated that it was quite evident that the disease was always present, the month of maximum frequency was August; 76 per cent. of the cases occurred in the months of August, September, and October. Two towns in Canada, Hamilton, Ont., and North Haltey, Que., reported an unusually large number of cases in which the disease assumed epidemic form. With regard to the mortality from the disease, there were 46 deaths among the 658 reported, or 7 per cent. The speaker announced that it was the intention of the Commission of Conservation of Canada to publish in the form of a bulletin a collection of the interesting information sent in by the members of the Canadian medical profession together with the latest information to be obtained from the several leading Canadian authorities. The etiology and pathology were discussed by Dr. D. A. Shirres of Montreal and the symptomatology and diagnosis by Dr. C. K. Russel, Montreal. Concerning the surgical treatment of the after effects of acute poliomyelitis Dr. A. MacKenzie Forbes, Montreal, said that in the months of degeneration and regeneration after an attack of the disease surgical treatment must go hand in hand with neurological treatment, and this surgical treatment must aim at the prevention of pseudoparalyses due to stretching and deformities due to contraction. At this period rest from weight bearing was indicated. It seemed to him, however, that mechanical appliances had a distinct but limited place in the treatment of the after effects of acute poliomyelitis. Having referred to the limited usefulness of braces and supporting appliances the spreaker thought it wise to mention that in the fashioning of a brace one must always bear in mind that its chief use was to preserve muscles and that it might, if carelessly prescribed, by constricting the limb and preventing free circulation and function condemn to greater deformity an already affected part. Thus braces should always be light, simple, and readily removable, non-constricting, and often removed. The speaker pointed out that tendon lengthening had taken the place of tenotomy but that the most interesting operative procedure which might be called for after acute poliomyelitis was tendon transplantation. In the discussion Dr. W. G. Turner urged the employment of massage after an attack of acute poliomyelitis, stating that in his opinion massage done skilfully was better by far in the treatment of such cases than was electricity. Dr. C. J. Edgar said that he had had an experience of an epidemic of poliomyelitis in which the majority of the cases

were of an abortive type. He had found urotropin of considerable value in treatment, in which opinion most of those present concurred. The consensus of opinion was that the employment of serum in combination with the administration of urotropin would be the treatment indicated. Some present advocated isolation of those affected and it was suggested that the common housefly may, in certain instances, be the means of communicating poliomyelitis. Dr. Russel in his paper stated that he did not believe the nose to be the chief seat of infection and was of the opinion that infection might be conveyed by insects, probably by mosquitos.

Of other papers read in the medical section that of Dr. A. E. Vipond of Montreal was especially interesting. It was a preliminary note as to the specific organism of scarlet fever. The conclusions which the speaker arrived at were as follows: (1) The bacillus had been obtained from seven cases of scarlet fever which came under his notice. (2) The bacilli would grow on all ordinary media, the growth occurring in three and a half hours. (3) The bacilli were to be found in the lymphnodes, where they multiplied and formed toxins which entered the circulation. (4) The bacilli had been inoculated into five monkeys and two rabbits. Typical scarlet fever developed in all, including rash, enlarged lymphnodes, and desquamation. No suppuration in any one instance took place at the point of inoculation. Streptococci would have been likely to produce this effect.

The Section on Preventive Medicine was one of the most important of the meeting. On the first day, the afternoon of June 7, the meeting was mainly devoted to a consideration of the milk question. The first paper read was by Dr. J. J. McCarrey, Inspector of Food in Montreal. He advised that steps be taken to effect improvements at the source of milk production by insisting on the rigid inspection of all milk-producing herds as a preventive of pollution. Sooner or later impure milk caused the deaths of the infants who drank the product. In those instances in which a man was wilfully negligent of the fact he became criminally responsible for the deaths wrought and should be severely punished. Where he was ignorant of the results of his carelessness steps should be taken to enlighten him for the benefit of the city or section of the country in which he lived. Tuberculosis might be readily detected by clinical examination in the case of human beings, but veterinary surgeons would often fail to diagnose bovine tuberculosis. He accordingly emphasized the need of employing the tuberculin test. Dr. T. P. Shaw of Montreal dealt with the use of milk as a food for convalescents, infants, and children, and stated that, while the improved conditions of modern living tended to decrease mortality, the same did not apply to the infant population under one year of age. In the opinion of Shaw all cities should establish bacterial standards for milk as well as standards for the food value of milk, all of which should be sold in sealed bottles. Pasteurized milk was to be preferred to the dirty unpasteurized product but it should be labeled as such and bear the date of pasteurization. Dr. J. E. Laberge of the Montreal Board of Health referred to the financial loss to the Dominion resulting from the employment of poor milk in the manufacture of its milk products.

Dr. F. H. Whitelaw of Edmonton and Lieutenant-Colonel Jones and Major Lorne Drum of Ottawa also read papers on the question of milk products and the supply of the products in their respective cities.

On June 8 Lieutenant-Colonel Jones of Ottawa read a paper on military sanitation. He said in part that military sanitation is in time of peace very different from military sanitation in time of war. The first was preparation, the second was realization. War means only one thing, the defeat of the enemy, and every effort must be exerted and every point strained to accomplish this end. The military sanitarian has a mighty force as his coadjutor, military discipline. Their success as military sanitarians in the mobilized Canadian militia would depend on the success obtained in discipline. An undisciplined army is an unsanitary army. Dr. C. A. Hodgetts of Ottawa contributed an article on infantile mortality. In this paper the very large mortality of infants under one year of age was discussed and it was pointed out that while in Quebec the mortality rate of infants under one year of age to 1,000 births was 128; in Ontario, 124; in Victoria, Australia, it was only 86 and in western Australia, 85. The speaker drew attention to the large death rate among infants from epidemic diarrhea. Poverty, he said, was not so great a factor in the causation of death of infants in Canada as in Great Britain. The death rate of infants in Ottawa was bad enough but the mortality of infants in Montreal was simply appalling.

On June 9 a symposium on typhoid fever and water supplies was held by the combined sections on medicine, preventive medicine, and laboratory workers under the chairmanship of Dr. T. A. Starkey, professor of hygiene at McGill University and chairman of the section of preventive medicine. This symposium was an unqualified success, the papers read were of a high quality, and several facts of much moment were elicited with regard to typhoid fever. Major Lorne Drum read a paper on the character of the recent epidemic of enteric fever in Ottawa, in which it was clearly shown that polluted water was responsible for its spread. Dr. John A. Hutchinson, medical officer of health, Westmont, read a paper on the character of the recent epidemic at Westmont, which was also shown to be waterborne. Dr. Starkey, in the absence of Dr. Brehm, medical officer of health, St. John's, Newfoundland, cited an instance of a lake in Newfoundland four miles long into a corner of which the drainage of one farmhouse and premises emptied, and one only. As a result the whole community which derived its water supply from that lake was infected with enteric fever. Dr. C. H. Douglas of Montreal described in a paper a large epidemic of enteric fever at Fort William, which was clearly demonstrated to be wholly waterborne. The clinical aspects of typhoid fever and typhoid-like infections were described in a paper by Dr. F. G. Finley, Montreal. Bacteriology of the same was discussed in a paper by Dr. Rhea, Montreal.

By the bacteriological means of diagnosis now at hand it was pointed out that a case of enteric fever could be diagnosed in twelve hours and vaccines used at once. The chief scientific interest of enteric fever from a bacteriological standpoint was centered in the paratyphoid group. The need now was for the bacteriologist to differentiate between the various members of the group. Lieutenant-Colonel Jones of Ottawa read a paper on water supplies as the chief channel of infection. He made a scathing indictment of the water supply of eastern Canada and he emphasized the fact that the treat-

ment of polluted water by hypochlorite of lime was but a stop-gap and must not be regarded as taking the place of filtration, the only effective means at present known for purifying a water supply. Professor Starkey said that there was little pure natural drinking water left in Canada and that all drinking water must be filtered if a recurrence of typhoid epidemics was to be avoided. A paper on typhoid carriers was read by Dr. J. C. Meakins, Montreal. The gist of the meeting was that epidemics of typhoid fever were generally waterborne and that the water supply of Canada was generally polluted.

Prof. Starkey also brought forward a most important point. It was to the effect that in most, if not all, epidemics of typhoid fever in Canada the paratyphoid, or typhoid-like, infections were numerous and sometimes preponderated. By typhoid-like infections was meant those which did not react to the Widal test. This view was concurred in by all present and Dr. J. G. Adami said that for the safety of the public all the paratyphoid infections should be considered under the head of enteric fever. Dr. Starkey for some years has insisted on the large number of typhoid-like infections which accompanied epidemics of enteric fever and has urged that greater attention should be paid by medical men to these infections.

The Use of Coley Toxins in the Treatment of Sarcoma. R. M. Green.
Does Appendectomy Always Relieve Symptoms? An Analysis of Results Years After Operation in 640 Cases of Appendectomy. C. L. Scudder and H. W. Goodall.
Interpretation of Laboratory Findings. J. W. Fisher.
Spina Bifida. B. B. Cates.
Consideration of Two Cases of Infantile Scurvy with Special Reference to Differential Diagnosis from Infantile Paralysis. F. P. Webster.
Malignant Lymphocytoma of the Mediastinum. The Report of a Case. O. S. Waugh.

Coley Toxins in Sarcoma.—R. M. Green states that the use of Coley toxins alone in the treatment of sarcoma is warrantable only in obviously inoperable cases and then as a last resort. The use of Coley toxins as an adjunct to surgery in the treatment of sarcoma, or as a prophylactic against recurrence, is advisable, though by no means of definitely established value. The preparation of the mixed toxins of *Bacillus prodigiosus* and *Streptococcus pyogenes* as a bacterial vaccine by the method devised by the author is quicker, simpler, and more accurate than their preparation by Coley's method, and the product obtained is equally efficient.

Appendectomy and Relief of Symptoms.—C. L. Scudder and H. W. Goodall find that the statement sometimes made that appendectomy is associated with distressing sequelæ is unfounded in their series of cases. Likewise the statement that appendectomy is often followed by no relief to symptoms is not borne out by these cases, 94 per cent. having been completely relieved.

Interpretation of Laboratory Findings.—J. W. Fisher states that many times the improper interpretation of laboratory results by clinicians is responsible for much unjust criticism of pathologists and needless groping in the dark by those who decline to avail themselves of these valuable adjuncts to successful practice. On the other hand, the pathologist would be more helpful to the physician or surgeon if he would study the clinical as well as the pathological side of the case. In conclusion, the author makes a plea for the more frequent use of laboratory tests, but with a proper correlation of all of the clinical findings, thus eliminating much that is haphazard in diagnosis.

Spina Bifida.—B. B. Cates, in reporting a case of this condition, calls attention to a step in the technique of the operation which concerns the closure of the spinal defect with osteoplastic grafts. In not one of his cases was there enough bone at hand to cover the opening, so he used the deep fascia by dissecting enough from without inward to cover over the defect when turned toward the middle line. This fascia is strong enough and dense enough to form a firm bridge. It is not necessary to overlap the flaps, simply stitching the edges together with fine catgut being all that is necessary. Indeed, he believes that he caused necrosis in one of his cases by imbricating the flaps, thus cutting off the blood supply.

Infantile Scurvy and Poliomyelitis.—F. P. Webster concludes that, although a careful history, a painstaking examination, and the therapeutic test will procure a positive diagnosis, the discrimination between infantile paralysis and pseudo-paralysis of scurvy is not so simple and definite as described by authorities, and that, in particular, the changed and protean character of recent infantile paralysis has introduced difficulties into the immediate differential diagnosis.

Malignant Lymphocytoma of the Mediastinum.—O. S. Waugh reports a case showing congenital absence of one kidney, ureter, and adrenal, and a tumor which had completely filled the mediastinum, infiltrated the heart and surrounding tissues, and by pressure had constricted the lumen of some of the large blood-vessels in this locality. Histologically the tumor was a lymphocytoma.

A Simple Method of Viewing Röntgenograms in Three Dimensions. M. Girsdansky.
A Simplified Technique for Retrodisplacement of the Uterus in Performing the Baldy-Webster Operation. A. L. Soresi.
Improved Technique for the Intravenous Administration of Salvarsan by Means of a Vacuum Burette. A. A. Uhle and W. H. Mackinney.
In What Treatment May the Tuberculous Have Confidence? P. Paquin.
The Effect of Artificially Induced Fever upon Some Chronic Inflammatory and Ulcerative Lesions. H. Neuhof.
Some Remarks Concerning Diagnosis by Inspection. J. G. Wilson.
A New Diluting Fluid for Counting Leucocytes. R. L. Pitfield.

Physiology and Pathology of the Thyroid Gland.—S. P. Beebe states that there is considerable evidence to indicate that iodine is combined in the thyroid as a diiodotyrosin, but the administration of this substance will in no way replace the action of thyroid extract.

Röntgenograms in Three Dimensions.—M. Girsdansky describes a simple method of preparing and viewing röntgenograms in three dimensions.

Simplified Technique for Baldy-Webster Operation.—A. L. Soresi suggests the use of a hairpin instead of thumb and artery forceps as a means of perforating the broad ligament on each side of the round ligament, of pulling out the round ligament, and of approximating it with its mate on the other side.

Intravenous Administration of Salvarsan.—A. A. Uhle and W. H. Mackinney describe their improved technique for this procedure by means of a vacuum burette.

Treatment of the Tuberculous.—P. Paquin reports good results following the use of *tuberculinum purum*. He does not employ products with strong reactive properties save for diagnostic purposes, and in no event does he depend wholly on tuberculin as a remedy. He applies every suitable remedial measure, basing all first on nutrition, and then on specific treatment, resting on Nature's self-creative antidotes.

Artificially Induced Fever and Inflammatory Lesions.—H. Neuhof states that the study of the effects of artificially induced febrile reaction upon chronic inflammatory and ulcerative lesions is far from complete, but it appears that enough has been observed by him to warrant the

statement that the administration of mixed toxins has had a readily observable and a beneficial effect in several instances. For his first studies, diseases have been chosen in which changes following injections could be readily seen and felt. As a means of artificially inducing fever, Coley's fluid was used. What influence Coley's fluid will have upon the many other forms of inflammatory and ulcerative disease remains to be determined. To the author's mind there is no reason to believe in a specificity of the effect of Coley's fluid in these cases; it has been employed merely because it is a ready means of inducing pyrexia.

Diagnosis by Inspection.—J. G. Wilson states that one should cultivate to the fullest extent the faculty of rapid and accurate observation. By constant exercise of this power of attention one can, in all probability, attain a greater degree of perfection in the art of diagnosis than at first thought possible.

New Diluting Fluid for Counting Leucocytes.—R. L. Pitfield recommends the following diluting fluid: Acacia gum, 20 grams; distilled water, 50 c.c.; mix, dissolve, and add glacial acetic acid, 50 c.c.; gentian violet, one decigram; mix, warm, and filter while warm through a wet filter. This makes a superior diluting fluid in counting leucocytes because it is viscid and for this reason does not flow out of pipettes easily, and these can be filled more accurately because the fluid flows much more slowly. Neater drops and of definite size may be slowly put up on the counting chamber.

A New Sphygmomanometer. P. Nicholson.

Retrospection and Introspection.—By H. C. Wetherill. See MEDICAL RECORD, July 8, page 103.

Tuberculin in Treatment of Tuberculosis.—J. Ritter states that tuberculin is a valuable remedy when the lesions are limited and the progress of the disease slow without much fever or systemic disturbance. It may also be useful in advanced febrile tuberculosis with fair appetite and digestion and little or no systemic disturbance. It must be used with caution in young patients with actively incipient cases and one should keep in mind that in recent infection and in exacerbations of old lesions the reaction may be severe. In inactive advanced cases where few bacilli are still demonstrable in the sputum it may be of use.

Treatment of Purulent Ophthalmia.—M. D. Stevenson states that in this condition the policy of treatment should be guided by four considerations: The careful, thorough use of proper antiseptics, efficient but not too irritating; watchful care over corneal and general nutrition; free drainage; and especially avoidance of even the slightest injuries to the delicate corneal epithelium. A bacteriological examination of the discharge should be made as soon as possible, and, while the author uses generally a 1 per cent. nitrate of silver solution in virulent gonorrheal infections, a 2 per cent. or even stronger solution for a few treatments may be better. In certain mild non-gonorrheal infections 0.5 per cent. is usually sufficient.

Retinal Hemorrhage.—F. T. Rogers concludes that three-quarters of all cases of hemorrhagic retinitis either terminate fatally within a few years or the patients suffer marked impairment of health. The existence of any form of hemorrhagic retinitis is suggestive of present or future disease of either the nervous or circulatory system. The duration of life in albuminuric retinitis increases with the age of the patient, and the younger the patient the worse the prognosis in point of time.

Cultivation of Treponema Pallidum.—H. Noguchi announces his success in cultivating this organism, employing the spirochete-containing testicular tissue of the rabbit.

Anaphylaxis in Carcinoma.—J. L. Ransohoff describes experiments in which pigs were sensitized with serum taken from patients suffering from carcinoma. He concludes that these experiments may develop into an aid to early diagnosis of carcinoma. There seems, too, a possibility of work of this nature opening up a channel which may eventually lead to true cancer immunity and treatment by serum.

Healing of Iridectomy Wounds.—A. Alt takes up in a general way the theories of glaucoma and of the beneficial effect of iridectomy in this condition, and comes to the conclusion that it is probable that the excision of a piece of the iris is the essential part of the glaucoma operation.

Congenital Hydronephrosis.—D. M. Eisendrath reports two cases of this condition. The special points noted are the diagnosis before operation, the congenital stenosis of the ureter as a cause of the obstruction to the escape of urine, and the fact that a large hydronephrotic kidney could exist practically without symptoms except abdominal enlargement and emaciation since birth.

Instrument for Rectal Operations.—W. J. Woolston describes a new instrument that he has devised, which is especially adapted for the Whitehead operation. It consists of a conical rubber plug upon which the operation is performed, occluding the bowel in such a manner that no contamination of operation or field of operation takes place.

Fracture of Humerus.—J. W. White reports a case of fracture of the anatomical neck of the humerus, with subcoracoid displacement of the lower fragment.

Infectivity of the Blood in Measles.—By J. F. Anderson and J. Goldberger. (See page 182.)

A New Sphygmomanometer.—P. Nicholson has devised a simple compact blood pressure apparatus.

Temperaments: Is There a Neurotic One? R. Jones.
Outlines of Medical Hydrology. R. F. Fox.
A Short Chemical Study of a Case of Cyclic Vomiting, with Some Remarks on Creatinuria and Acidosis. E. Mellanby.
The Physiological Ideal in the Artificial Feeding of Infants. J. Snowman.
Success or Failure in Electrotherapy: A Consideration of Some of the Causes. S. Sloan.
A Case of Trophoneurotic Anemia; A Sequel. T. W. Parry.

The Neurotic Temperament.—R. Jones states that genius may often prove to be a golden idol with feet of clay. Man is firstly a vertebrate mammal with the instincts of the animal, but he has the power of inhibition and of autocriticism, and through the influence of his environment he has attained a veneer of civilization, and it is interesting to note that in insanity these acquisitions of his progress are gradually dissociated and shed in the inverse order of their acquirement, until at last man is left a wreck barely above the level of the animal. The cause of this reduction in insanity is probably some physical process in the cortical cells, or, in other words, some chemical change has occurred in the neurones, either directly through the influence of some poison generated from

within or introduced from without the body, or indirectly by means of the environment, favored, of course, by some inherited predisposition; and it is the study of man biologically—that is to say, the observation of his general activity or his total reaction under the influences of physical and psychological impressions—that enables us to infer the kind of temperament a man possesses. The predisposition to states of instability of control may be associated with distinguished mental superiority, and it is the degree of sensitiveness to pleasure and pain, the degree of motor restlessness, and the degree of emotional tone exhibited by the individual which justify us in concluding that there is or is not present a temperament which one is entitled to describe as the neurotic, and it is by foreseeing this temperament that one can promote happiness and harmony where otherwise there would be intolerance, strife, and discordance.

Medical Hydrology.—R. F. Fox defines medical hydrology as the science of waters, vapors, and mineral or organic deposits in connection with waters, as used in medicine, both by internal administration, and in the form of baths and applications.

A Case of Cyclic Vomiting.—E. Mellanby reports the case of a boy six years of age who had had attacks of vomiting and great prostration almost every month since birth. There was an extremely rapid loss of weight during the attacks. The child was never normal because he always excreted creatin. The cause of the attacks was always at work. The creatin excretion rose considerably several days before the attack, so that by the estimation of this substance it was possible to predict the onset of symptoms. Acidosis had nothing whatever to do with the attack, but was only an episode like any other symptom. And this for the following reasons: (*a*) the child's power to metabolize fats was quite normal; (*b*) acidosis started after the onset of symptoms and cleared up, on giving glucose, before their abatement; and (*c*) a condition of acidosis for four days in a quiescent period was accompanied by no trace of ill-effect. It is thought that the condition of recurrent vomiting is due to some intestinal intoxication which may or may not depend on bacteria. It is suggested that such a condition might depend upon an accumulation or excessive formation of β-iminazol-ethylamine in the intestinal wall.

Artificial Infant Feeding.—J. Snowman states that on chemical, physiological, and clinical grounds lactalbumin demands a permanent position in all cow's-milk mixtures intended for infant use.

Electrotherapy.—S. Sloan states that the employment of electricity as a sole remedy eliminates all other sources of possible success or possible failure, and makes for education in correct electrotherapy. This is of value in the early practice of the art, but, without doubt, once sufficient experience has been gained, the best results will be obtained by utilizing to the full all the resources of the healing art—electrical, medicinal, dietetic, physical, psychic: and he is the most successful physician who has his quiver full of such weapons and who, in cases of difficulty, is fertile in resource.

Trophoneurotic Anemia.—T. W. Parry reports a case of profound anemia in a female patient in which the apparent cause at the outset was nervous shock. The condition was temporarily relieved by intramuscular injections of an arylarsonate.

Remarks on a Case of Sporotrichosis. N. Walker and J. Ritchie.
Carcinoma of the Larynx: Extirpation of Primary and Secondary Growths: Glandular Recurrence: Treatment with Thyroid Extract: Disappearance of Growths. R. H. Woods.
Some Cases of Chronic Jaundice in Which Opening the Duodenum Was Required. H. B. Robinson.
On Two Cases of Removal of Part of the Pericardium and Its Repair by Means of the Pectoral Muscle. A. W. Mayo Robson.
The Sulphur Miners of Sicily: Their Work, Diseases, and Accident Insurance. Sir Thomas Oliver.
Experiments on the Restoration of Paralyzed Muscles by Means of Nerve Anastomosis. R. Kennedy.
A Subtemporal Decompression Operation for Intracranial Pressure. J. Stewart.
Blue Sclerotics and Brittle Bones. H. Burrows.

Sporotrichosis.—N. Walker and J. Ritchie state that cases of sporotrichosis can easily be overlooked. To ensure that the primary cultures shall be pure, material from unbroken lesions must be obtained and the difficulty of microscopically demonstrating the fungus in the lesions, the necessity in many cases for the use of media containing sugar, the special thermal relationships of the organism, the non-appearance of visible growth till several days after inoculation, the peculiar miscroscopic appearances which often suggest the presence of yeasts, the relative insusceptibility of the guinea-pig to inoculation, all open up paths for the organism being missed. Further, the marked therapeutic effect of potassium iodide may suggest a diagnosis of syphilis and obscure the recognition of the true condition present. It is obvious, however, that in all granulomata, especially of the skin, which cannot be clearly attributed to the ordinary causes of such lesions, the possibility of sporotrichosis should be kept in view. Usually, if such precautions as those detailed be observed, little difficulty will be experienced in the fungus being isolated, if it be present

Carcinoma of the Larynx.—R. H. Woods reports a case of extirpation of the larynx for carcinoma, in which cancerous recurrences in the lymphatic glands of the neck were caused to disappear by the administration of thyroid extract.

Chronic Jaundice.—H. B. Robinson reports observations made upon ten cases in which it was found necessary to explore the duodenal end of the bile duct to unravel the cause of a more or less persistent jaundice.

Removal of Part of Pericardium.—A. W. Mayo Robson reports two cases: one of columnar-celled carcinoma involving the pericardium; the other a chondrosarcoma involving the pericardium. In both of these a considerable portion of the pericardial walls was removed, and the gap efficiently covered in by a flap taken from the pectoral muscle.

Diseases and Accident Insurance Among the Sulphur Miners of Sicily.—Sir Thomas Oliver describes his investigation of the conditions surrounding the work of the 40,000 sulphur miners of Sicily. The principal accidents are fracture of arms and legs due to falls of stone from the roof, fractures of the bones of the feet, and injuries to the head by falls of stone. Beyond conjunctivitis due to irritation of the eyelids by sulphurous acid and sulphuretted hydrogen, eye affections are not common. Trachoma is sometimes met with. The men are occasionally asphyxiated through unexpectedly inhaling sulphuretted hydrogen and carbon dioxide gases given off from the bituminous clay and the naked lights used in the mine by the men and boys. Of the 5,000 accidents which occur annually 1,200 happen to the boys who carry the ore from the depths of the mines up a long and treacherous flight of stairs to the surface. Fifty per cent. of the accidents happen to the diggers. An invalid fund has been or is about to be opened for the sulphur miners. It will be managed by the state, and to it the owners and leaseholders will contribute 1½ francs per ton of sulphur. The workmen will not contribute to this fund. An efficient system of accident insurance has been in force for some time. The Sulphur Miners' Insurance Society is not a state-managed fund, although it is obligatory upon employers and leaseholders to contribute to it. The workmen do not contribute to the fund. The tariff is 2 francs per ton of melted sulphur. The amount of money raised from employers is 800,000 francs per annum. Of this, 250,000 francs are spent upon medical

and surgical requisites, including payments to doctors and their assistants. The Red Cross Society receives a special allowance of 100,000 francs a year. There are in Sicily 112 medical men connected with the insurance society, but all doctors must, according to law, render first aid, if called upon to do so, and for this service they receive 7 francs. In Caltanissetta there is a consulting staff of three medical men, each of whom receives 3,000 francs a year. It is the duty of these medical men to visit the injured and to furnish a report to the director of the insurance fund. In 1909 over 2,000 medical visits were made. The benefits of the insurance fund are only extended to men and boys who have been injured in or in connection with the sulphur mines, and to relatives of persons who have succumbed to injuries. If death supervenes after an accident, five years' wages are paid to the relatives of the deceased miner; the average amount paid is 3,000 francs, but this sum is regulated by the wages which had been received by the workman. Every injured miner is entitled to 2.40 francs per day. For ordinary sickness little provision has as yet been made; but in the event of an acute illness, such as pneumonia, employers will frequently render financial assistance to a sick miner, in the hope that, when he returns to work, deductions can be made from his weekly wages. To the estblishment of the insurance fund there was considerable opposition on the part of the employers on account of expense; but a more beneficent scheme could hardly be conceived. It is now regarded by all as an excellent institution. The syndicate has appointed three experienced inspectors to visit the mines and to offer suggestions to the owners as to the means whereby accidents may be prevented. These appointments have been productive of good. After every accident a report is sent to the state mining office, the police, and the insurance fund. It is sufficient if the announcement is sent by telegram. In addition to the above there are also fourteen under-inspectors, who are paid by the fund to assist in a general way. These men frequently assist the surgeons in dressing wounds, etc. In the event of an accident proving fatal a post-mortem examination is always made; this is attended by two medical men, one of whom is an official of the insurance fund, while the other is appointed by the magistrate of the district. Since the establishment of the insurance fund lawsuits, which used to number 200 a year, have fallen to 60. In 1905 the accidents numbered 9,000; in 1909 they had fallen to 5,000, owing to greater care, improvement of methods, and mine inspection. The period of temporary invalidity after accident used to be twenty-five days; the year before last it was sixteen and a half days. Injured miners receive pay from the first day of the accident. In consequence of the frequent visits of the official surgeons, whose report is final, malingering has been reduced to a minimum. An injured miner has one alternative, and that is to apply to a judge, who, if he deems it necessary, can send a doctor to examine the patient, and, if the medical report is contrary to that of previous examiners, the judge may reopen the case and settle it. The cost of the administration comes to 140,000 francs a year. The sum paid to injured workmen in 1905 was 700,000 francs; in 1909 it was 300,000 francs. Colojanni maintains that the terms arranged for the injured sulphuric miners of Sicily are better than those for the ordinary miner in Germany.

Nerve Anastomosis.—R. Kennedy states that on failure of spontaneous recovery from facial paralysis anastomosis with the spinal accessory or hypoglossal holds out the most favorable prospects of recovery.

Subtemporal Decompression Operation.—J. Stewart reports a case of fracture of the vault of the skull with extradural hemorrhage, in which a successful decompression operation was performed.

Blue Sclerotics.—H. Burrows presents a genealogical history showing a definite connection between fragility of the bones and blue sclerotics.

Berliner klinische Wochenschrift.

June 19 and 26, 1911

Action of the Tropical Sun on Mankind and Animals.—Aron of the Philippines has subjected this problem to experimental research. To what extent is the great morbidity of white men in the tropics due to the light rays and to what extent may this morbidity be cut down by exclusion of these rays? Aside from the latter one has to contend with dampness, heat, precipitation, winds, and air pressure. Again, aside from the quality of the invisible chemical rays, the visible heat rays as well must pass almost vertically through the atmosphere, which is thereby prevented from that absorption of light which occurs even in the warmest temperate climate. At Manila the intensity of the light rays is from five to twenty times that of Chicago in the month of June. On the other hand the actinic spectrum in the Philippines has been found to be not more extensive than that further north. To make of the chemical rays an essential factor in tropical morbidity seems unwarrantable *a priori*, and experiments as to a hostile action of these rays on soldiers appear to have ended with negative finds. The unfavorable action of moist heat, as compared with that of chemical rays, is thoroughly comprehended and has never been in dispute. To study the effects of heat rays alone the chief available resource is surface thermometry. The surface temperature in tropical shade is normally about 33° C. When the skin is exposed to the heat rays the temperature tends to rise to blood heat, but with continued exposure the skin perspires freely and the temperature falls. The dark skin of the native absorbs heat more rapidly and perspires more markedly. It probably does not on this account reach the high mark of the white skin. Sensible perspiration dehydrates the surface without cooling it, the cooling action being due to the non-apparent evaporation. In an atmosphere saturated with humidity evaporation is necessarily interfered with. The white man's clothing also antagonizes evaporation; yet if he go naked the local action of the chemical rays is at once apparent. Muscular exertion tends to raise the temperature and heat stroke most commonly follows the combination of direct exposure and muscular labor. The author's experiments on apes tend to show that when exposed to direct solar radiation these animals exhibit no more immunity to the latter than do unacclimated white men. They are able to live and flourish in the tropics only because they live in the shade.

Psychical Disturbances After Lightning Stroke.—König gives this subject brief monographic consideration and reports one case in great detail. Aside from the burns the condition after the stroke, which may persist for months, is essentially neurasthenic. There are weakness of the legs, instability of the heart, tremor of the hands—in short evidences of traumatic neurosis. The author's female patient developed five years after the injury a severe hysteria. Such a sequence is so far from unique that it has been reported as very common after electric injuries other than lightning strokes. Hence for a variable period after injury the patients should be in a condition of latent hysteria. In the author's patient, however, the hysteria was preceded by dyspeptic symptoms and malnutrition. The hysteria was severe in type and notably polymorphous. Patient may not have been an intact individual from the psychopathic viewpoint, but this could not readily be shown. However, analogous mental phenomena have been noted in intact subjects. The psychical disturbances were largely such as pertain to severe hysteria, but the alteration could not entirely be accounted for on that hypothesis. Various hallucinations appeared to give rise to imperative concepts with suicidal tendencies. The pa-

tient made a good recovery from the entire morbid state and resumed her original position in the world.

Suprarenal Hemorrhages in the Newly Born.—Magnus points to the frequent occurrence of suprarenal hemorrhage in autopsy cases of the newly born, including the stillborn. He himself has notes of eight cases in a total material of 124 children in which the hemorrhage was plainly evident to the naked eye. Apparently a routine microscopical study of these cases is impracticable, yet evidence enough exists to show that this lesion should be present in a very large percentage of all dead newly born. The lesion is very frequently present in the dead fetus, while conversely it tends to become more and more infrequent with age, until in dead adults it is found to the extent of but 1 per cent., While the significance of the find doubtless varies, it undoubtedly stands in close relationship with asphyxia during labor and following different postpartum accidents. It is believed that a material predisposition to this accident may exist, for we have no reason to believe that it occurs so often in children who survive.

Irregular Course of Nerve Syphilis.—Benario, representing his chief Ehrlich, retorts to those who allege the existence of serious nervous lesions due to salvarsan that the natural march of nerve syphilis is characterized by great irregularity of evolution; so that whatever method is used for treating this affection may seem at times to stand in causal relationship to certain symptoms. Cerebral syphilis may supervene with greatly varying frequency and precocity and may appear in many clinical forms. We know a great deal concerning the central and peripheral lesions of syphilis which affect the eye, and we have also definite information of the character of eye affections due to arsenic; and a comparison of the two shows that accidents in the course of salvarsan treatment have thus far been essentially syphilitic. This is the conclusion of so eminent an ophthalmologist as Deutschmann. Such relapses occurring in a subject presumably under the influence of salvarsan, so far from furnishing a contraindication to further use, constitute an earnest indication for a renewal of the injections.

Combinations of Arsenic and Mercury in Syphilitic and Metasyphilitic Lesions of Nerve Substance.—Frey believes that a double salt of mercury, the salicylate and arsenite, is not only a superior remedy for actual nerve syphilis, but one able to modify favorably the beginning of tabes dorsalis. He is practically silent in regard to paresis. Of a considerable number of patients treated, notes of forty-six cases are sufficiently complete for analysis. There were sixteen cases of ophthalmoplegia considered as of tabetic origin, with eleven complete cures of this symptom. The lightning pains disappear in a large proportion of cases, and this is true of the gastric crises. The ataxic gait was not favorably influenced. As the rigid and unequal pupils also responded to treatment to a notable extent, it may be claimed that a majority of the classic symptoms of early tabes show a marked tendency to yield to the remedy. The Wassermann reaction also disappears in these cases. The technique is that commonly in use for mercurial injections, and there were neither local nor general by-effects.

Behavior of Inflammatory Formations in the Skin toward Tuberculin.—Sternberg begins by calling attention to the negative results of von Pirquet's skin reaction in tuberculous children with measles. Following up this phenomenon he has tested the diagnostic resources in as many inflammatory skin affections as were available in tuberculous subjects. The latter furnished their own controls, for the uninflamed integument chiefly gave a positive reaction. A typical case is given: Age seventeen. General condition good, afebrile. Possible apical involvement. Syphilitic periostitis of tibia. On right forearm an extensive lesion suggesting the query "syphilis or tubercle?" Von Pirquet reaction in the healthy integument positive. Wassermann positive. A piece of skin excised for microscopic study gave indecisive results. The von Pirquet was then tested in the cutaneous lesion, and the positive results appeared to show decisively that the lesion was tuberculous. For according to the author's studies a nontuberculous lesion should have given a negative result. The chief value of the test to the practitioner is summed up in the preceding.

Anus Vestibularis.—Pfeifer states that this is one of the rarest of malformations, only thirty-four cases being on record. His own case was the first in 4,500 women to be examined. Even this proportion is larger than that which usually obtains. Of the thirty-four women, eleven gave birth to children, while the others represented the unmarried and sterile married females. The author's case occurred in a girl aged nineteen who was of healthy stock and free from other malformations. However, of ten children in her generation only one was raised beside herself, all others dying in early childhood. Patient has been married three years and never menstruated until after marriage and then only at six to eight weeks intervals. She came to the clinic for dysuria and fluor albus. Examination readily revealed the malformation. The uterus was anteflected and hypoplastic. Patent ductus Botalli was found by following up a systolic murmur. The malformation was not a physical handicap to the patient, since the sphincter muscle was present and there was no fecal incontinence.

Demonstration of the Kidney Pelvis and Ureter by Röntgenography.—Von Lichtenberg and Dietlen refer to the collargol method of pyelography, first described in 1906, as the earliest phase of Röntgen demonstration of this part of the body. Up to that time we had only the shadows of calculi when the latter were present to give us any information as to the kidney pelvis and ureter. Distention of cavities with air with a view of rendering them visible is almost as old as röntgenography itself and inflation of the ascending colon to produce an illuminated background for calculus shadows goes back many years. The urinary bladder has been inflated both with atmospheric air and oxygen with a view of rendering vesical calculi apparent. The same resource had been suggested for the kidney pelvis, but the present writers are evidently the first to carry out the idea. Three patients were tested, two of them on both sides. Only one suspect had stone, the information in the two others having a negative value. The oxygen in the tank was under low pressure and was conveyed into the ureter through an ordinary ureteral catheter of 5 to 6 caliber. The authors have made, all told, about 200 pyelographs and regard the oxygen method as a decided addition both to positive and negative diagnosis, and as a safe procedure, despite some theoretic objections.

Significance of Urochromogen for the Prognosis and Therapy of Pulmonary Tuberculosis.—According to Weisz excretion of urochromogen in pulmonary phthisis, as well as in other infectious diseases, is the expression of a toxic disturbance of the cellular metabolism, which appears as soon as the toxin enters the circulation. This does not happen in phthisis as promptly as in typhoid fever, measles, sepsis, etc., which are toxinemias from the outset. The renal excretion of urochromogen in tuberculosis should occur parallel with the development of fever. As has been known since the first application of the diazo reaction in tuberculosis, the more constant and the more marked the excretion of urochromogen the graver the prognosis. The same is true of the other affections. As always happens, however, ironclad laws cannot be laid

down under these circumstances, for cases do end favorably after pronounced diazo reaction. The unfavorable character of the prognosis is bound up largely in the extension of the disease, and even severe local destruction is not necessarily conterminous with a fatal ending. The reaction may be conceived as illustrating a progressive weakness of resistance on the part of the cells of the body to the disease, which is further shown in the lessened demand of the tissues for oxygen. But in a case of this sort the grave prognosis may be offset by our therapeutic resources, as in a case cited by the author of recovery in a desperate case due to establishing an artificial pneumothorax.

The Rumpel-Leede Scarlatina Phenomenon.—Mayr has examined 100 patients with diseases other than scarlatina for the presence or absence of this phenomenon, which consists in the appearance of minute subcutaneous hemorrhages below the area at which a rubber bandage is applied not too tightly for ten minutes upon the upper arm. Twenty patients gave a positive result, innumerable minute hemorrhages appearing just below the level of the bandage. Five patients, all women, had tuberculosis (lupus vulgaris), ten had lues, two eczema, two psoriasis, and one gonorrhea. More women reacted than men, yet by far the greater number examined were males. The reaction simply means that the capillaries are very friable, a state of affairs undoubtedly common in scarlet fever and due largely, perhaps, to the toxins of the disease. In such affections as lues, lupus, etc., in which the phenomenon has been noted there are also circulating toxins. The presence of the hemorrhages in conditions like eczema and psoriasis may indicate a capillary friability of a different and unknown nature.

Specificity of the Plaut-Vincent Angina Microrganisms.—Blühdorn concludes from his studies in the Rudolf Virchow Hospital that fusiform bacilli and spirilla are to be found, now sparsely, now in abundance, simply or in combination, in a great number of throat smears from the healthy. About the teeth and gums they are found almost constantly. They are also present in the most varied anginose affections, as diphtheria, scarlatina, syphilis, in varying association with known saphrophytes. When these bacilli and spirilla can be obtained in pure or nearly pure cultures, so that all other diseases can be excluded, they can set up a specific condition, the so-called Plaut-Vincent angina. They are then responsible not only for anginous processes but also, at least in part, for ulcerous lesions. Because of the notable parallelism between the pathogenic activity of the Klebs-Loeffler bacillus and the Plaut-Vincent microorganisms the latter should be amendable to serotherapy.

A Pathogenic Factor in Cholecystitis without Stone.—Solieri emphasizes the fact that biliary calculi are by no means essential for the production of biliary colic. In 1905 at least thirty-seven cases had been documented in which no stone was present. In the majority the pain had been caused by simple distention of a gall-bladder the seat of acute cholecystitis. The pain, whatever the cause, is due to expulsive efforts of the bladder. Another occasional obstructive cause is a blood clot and the author relates a personal case of this type occurring subsequently to typhoid fever. Blood clots sometimes complicate obstruction by calculi, and more or less blood may be present in simple distention to the presence of which it has naturally contributed. If much blood is present there is a presumption of an ulcer in the mucosa, and if ulcerative cholecystitis were not a very rare condition biliary colii would doubtless be much more common.

Clinical Researches with Ovarian Substance.—Offergeld states that the ovary appears to preside in some way over the metabolism of morganic matter, and hence aids in maintaining the composition of the blood. Thus when young bitches are castrated there is an initial reduction of the number of erythrocytes and amount of hemoglobin. Several eminent authorities regard chlorosis as a condition wholly secondary to ovarian disease or disturbed action. It has therefore been proposed to use ovarian extract, with or without organic iron, for this affection and also for simple anemia. In these conditions the ovary and uterus may seem free from disease, but are often hypoplastic, while functional menstrual affections are commonly present. In cases of infantilism of the genitals it is asserted that the use of ovarian extract has been followed by pregnancy. The efficacy of the remedy for climacteric disorders is well known. The author is at present testing the substance in the toxemia of pregnancy.

Guinea-Pig Paralysis and Acute Anterior Poliomyelitis in Mankind.—Römer of von Behring's staff announces that a form of paralysis occurs spontaneously in the guinea-pig which bears some resemblance to infantile paralysis in man. This occurs sporadically and the paretic factor is an end phenomenon of a prior involvement of the nerve centers. The same affection may be propagated artificially by intracerebral inoculation, a latent or incubation period of from nine to twenty-three days preceding the systemic reaction. The latter comprises a temperature rise, loss of weight, and an increasing muscular hypotonia. Vesical paralysis may or may not supervene. The muscular weakness is much more pronounced in the posterior extremities. The disease is propagated by inoculating emulsions of brain and cord and the bacterial cause has not yet been isolated. This affection has not been assumed to be identical with the Heine-Medin disease in man, for, with the exception of the ape, all lower animals tested, including, of course, the guinea-pig, have proved refractory to inoculation with the virus of the human disease. The two affections may, however, belong to a common group disease.

Purulent Labyrinthic Meningitis and Its Operative Management.—Stacke states that there are cases of acute purulent meningitis which are propagated from the labyrinth and which are curable by operation, provided that intervention is sufficiently prompt. We must always have in mind the classic symptoms of labyrinth involvement—vomiting, vertigo, fever, severe headache. Of these, vomiting is the most serious. But this syndrome may be present in menigitis alone, *i. e.* in monotogenic meningitis. Lumbal puncture should therefore be practised as soon as there is suspicion of labyrinthitis. If the spinal fluid is still clear and uncontaminated and if there are a history and evidences of a chronic middle ear inflammation the radical operation for the latter may be undertaken without opening the labyrinth. If the severe symptoms do not yield we must now be prepared to attack the labyrinth, provided that it can be shown beyond doubt that pus is present in the latter. We learn of this through repeated lumbal puncture which reveals the presence in the fluid of leucocytes from the subarachnoid space. The very first signs of purulent meningitis furnish us with the cue to operate. It is not always to be expected that the meningitis will be aborted, but widely attacking the labyrinth in these cases must be regarded as a decided step forward in aural and cranial surgery.

Physiological Action of Light in the Kellogg Light Bath.—Brustein sums this up as follows: The electric light bath acts doubtless upon the association motor reflex of man by altering the degree of its constancy and excitability. This action differs with the color of the light. Colorless and blue glass strengthen the constancy and augment the excitability of the association motor reflexes. Red glass exerts the opposite action. Hence the action of the bath depends upon the spectrum and it is not a matter of indifference how the light is applied.

Insurance Medicine.

ANNUITY INSURANCE FOR PHYSICIANS.

To the Editor of the Medical Record:

Sir:—I have read with much interest your editorial in the issue of July 8, on Annuity Insurance for Physicians. I think that form of insurance is ideal for physicians and for professional men in general, but the annuity should be such as to cover the wife as well as the husband. I have two such policies, both of them issued on the limited payment plan, so that my payments continue only during the years of greatest activity; then, after the lapse of a certain length of time, the annuity becomes payable, and I receive the annuity as long as I live. In case of my death, however, the annuity at once becomes payable to my widow as long as she lives, and if we both die before ten payments have been made the rest of those payments are made to my estate.

Investigation has shown that very few women can successfully manage any considerable sum of money suddenly turned over to them on the death of a husband, and, as a rule, within a year or two the money is all gone. If, however, the widow is a better manager, the money is a matter of court record, and the tax inquisitor is on hand to see that she pays taxes on the full amount. If, however, instead of a lump sum, payments are made to her in the way of annuity, the amount which she will annually receive will be much larger, she is relieved from all vexations as to taxes, and the principal cannot possibly be dissipated.

The Undeveloped Field in Life Insurance.—(See page 181.)

Accident Insurance Among the Sulphur Miners of Sicily.—(See page 192.)

Auscultation in Life Insurance Examinations.—*The Lancet* presents the substance of a paper recently read before the Life Assurance Medical Officers' Association by R. A. Young, and entitled "Some Auscultatory Problems in Insurance Examinations." The author reviewed the difficulties of interpretation of auscultatory physical signs encountered by the medical officer during the course of the routine medical examination prescribed by most insurance companies. He pointed out that the newer methods of diagnosis applicable in ordinary medical practice are for the most part not available for the use of the insurance examiner owing to the expense and delay involved, and that the history given by many proposers is scanty and often misleading. The examiner is, therefore, left to establish the absence of disease armed chiefly with a tape measure, a weighing machine, a stethoscope, a few testing reagents, and his otherwise unaided senses, unless he is assiduous and well equipped, when a microscope may be pressed into service occasionally. The stethoscope is, therefore, of great importance, and the information it yields requires careful consideration, since it is not sufficiently emphasized that departures from the generally accepted normal standards of auscultatory sounds are not uncommon and are yet compatible with perfect health. The differentiation of these conditions from those which are the index of commencing disease or the stigmata of past attacks is obviously of great importance from an insurance standpoint. In connection with auscultation of the heart the author discussed the significance of variations in the rate, rhythm, intensity, and quality of the heart sounds and the differentiation of murmurs indicative of serious organic derangement of the valves or muscle of the heart from those of functional or exocardial character. In connection with the rhythm of the heart sounds, the question of irregularity or arrhythmia was discussed at some length. The general conclusions arrived at were that a single irregularity in a young subject in association with respiration is of no serious importance, even though there may be a history of occasional slight syncopal attacks and even if an exocardial murmur be present. Cases with irregularities due to smoking and to overindulgence in tea and coffee may be accepted after postponement on trial. Extra systoles in young and middle-aged people are not necessarily of serious character in the absence of arteriosclerotic changes and of signs of cardiac enlargement, but should be regarded with suspicion and probably declined. Irregularities due to heart-block, to weakened muscular power, and those associated with valvular or myocardial lesions cannot be considered as insurable on any terms. In connection with organic murmurs, the difficulties met with in some cases of mitral stenosis and of aortic regurgitation were discussed, and the importance of auscultating in both the erect and recumbent positions was emphasized. The various functional and exocardial or spurious murmurs were categorically considered and the features by which they could be recognized were outlined. The problems afforded by auscultation of the respiratory system were described as no less difficult than those in connection with the circulatory mechanism. The physiological differences in breath sounds and in voice sounds occurring at the right apex and over the right upper lobe were carefully worked out, and the distinction from the signs of early tuberculous disease was discussed. The nature of cog-wheel breathing and of the cardiorespiratory murmur so commonly heard in normal chests was considered, and it was stated that true jerky or cog-wheel breath sounds heard constantly at one apex and at a distance from the heart, so that a cardiac systolic origin of the cogging can be excluded, are very suggestive of early tuberculous deposit and must lead to careful search for other physical signs. In connection with the breath sounds, the occurrence of muscular sounds heard in shivering or in emphysema was also referred to as requiring care in some cases. Various spurious râles, creaks, and clicks due to fascial movements, to deglutition of saliva, and to movements of the head were described, and also the atelectatic rales heard in the infraaxillary regions of many normal persons. Probably most practitioners, both in ordinary practice and in insurance work, have been faced with problems such as those referred to, but their collection in this paper serves a useful purpose and should be of value, especially to the occasional examiner for insurance purposes.—*The Lancet*, April 15, 1911.

Subnormal Risks.—Zahnbrecher says that these may be defined as such applicants as offer more than the usual risk in insurance and therefore must be either refused insurance altogether or insured at increased premium. This definition is an empirical one developed from insurance experience and having nothing to do with medical science. There is always something positive about such applicants which makes them subnormal, while normal applicants, on the other hand, are marked by the negativeness of their characteristics: the latter are not ill, their family history is negative, they have had no previous illnesses, their occupation, habits, dwelling place are not of significance so far as their health is concerned. However, only in theory are there many such normal people. Almost everybody has some element of weakness and the question is how much of such weakness may coexist with the term "normal" for insurance purposes. Insurance experience answers thus: such applicants are normal so long as the group of insured persons possessing like defects show no larger mortality than the average mortality of the corresponding class of society. The degree of subnormality may then be measured by the increase in mortality in any group of applicants. The meaning of subnormality is accordingly a vari-

able one for the time and the class of society and depends as well upon the differences in the mortality statistics of different societies. Life insurance companies, however, cannot wait for the perfection of social statistics but must act every day with reference to this problem, as they must and do insure "subnormal" individuals constantly. The sentence "reject all you must and accept all you can" directed by English life insurance societies to its examiners has long ago become the guiding rule of international insurance practice. Medical science simply points out the signs of subnormal physical condition; only statistical study can make these medical facts of use for insurance purposes. Both German and foreign insurance companies have studied the question of subnormal applicants from this point of view and lately the Dutch insurance interests have even founded a special organization for the study of this problem of insurance. Medical selection among the applicants is the work of the medical director of each insurance company. He reports his views of the expectation of life of applicants, noting whether the individual applicant may be expected to enjoy the average normal years of life for his class and condition or whether he belongs to the subnormal class. His difficulty is not in deciding medically the existence of this or that abnormality, but the amount of extra risk assumed by the company in insuring such an applicant, a difficulty in which mere medical science is of little help. There are no uniformly accepted rules of conduct in such cases because the statistical studies mentioned above have not yielded uniform conclusions, and this explains the different attitudes assumed by the different life insurance companies toward the insurance of "subnormal" applicants. *Blätter für Vertrauensärzte der Lebensversicherung,* January and February, 1910.

Diabetes and Life Insurance.—Brodtmann states that many insurance companies have substituted Nylander's for Trommer's test for sugar. Nylander's test is more sensitive and is less frequently positive in cases of other reducing substances in urine. The most important thing remains in establishing rules for distinguishing glycosuria from diabetes, which is possible in most cases. Non-diabetic glycosuria includes alimentary glycosuria, also called physiological or glycosuria e saccharo; certain organic glycosurias are likewise non-diabetic. In alimentary glycosuria the percentage of sugar is small, usually below 0.05 per cent., but it may reach 0.1 or even 0.2 per cent. The latter cases have probably been insured in the past, when Trommer's test alone was used, and in most cases no diabetes developed later. Alimentary glycosuria depends upon the temporary appearance of sugar in the urine after the ingestion of large quantities of sugar or sweets. Most persons show such glycosuria after being given 100 grams of sugar in the morning, on an empty stomach; this is named pure glycosuria e saccharo, while if the sugar is given after or with a meal and glycosuria results, it is called alimentary glycosuria e saccharo.

Organic glycosuria depends upon disease of some organ resulting in the appearance of sugar in the urine. Such cases must usually be included among diabetics; among the diseased organs may be named the liver, pancreas, thyroid gland (Graves' disease), brain (apoplexy, cerebral syphilis, tabes dorsalis, paralysis agitans, trauma, traumatic neuroses, etc.). Frequently the disease of the organ alone excludes the applicant

Functional neuroses and neurasthenia form the only practical difficulties. Many neurasthenics show glycosuria, which disappears with improvement of the underlying condition; such applicants should not be excluded. Every applicant with glycosuria must be examined many times and at fairly long intervals. Careful inquiry into the family history must be made, especially in reference to gout, obesity, and diabetes; Naunyn says that 30 per cent. of diabetics give a positive family history. Of course, diagnoses cannot be expected of applicants, but they must be helped to remember any symptoms in their relatives that may give the right clue to the examiner. Reexaminations of the urine must be made after the usual diet and after 100 grams of sugar have been given in the morning. If the quantity of sugar remains small, if it does not rise above 0.1 per cent., for instance, or remains the same after the administration of sugar, the case is probably one of physiological or alimentary glycosuria. Six months should be enough in which to make several urinary examinations and finally decide whether the applicant should or should not be insured. The cost of such examination should be completely covered by the protection of the insurance companies against insuring diabetics and by non-exclusion of applicants with glycosuria that are otherwise acceptable. —*Zeitschrift für Versicherungsmedizin,* January, 1911.

Some Observations on Build.—Oscar H. Rogers records on a single table the heights and weights at different age groups of 104,000 insured women. The Shepherd table was based on about 75,000 men brought together for the association by Dr. George R. Shepherd's committee. In 1900 the American Fraternal Congress brought together about 135,000 men and the table published by that society corresponded so closely with the results obtained from the Shepherd table as to give very good grounds for the belief that there are now reliable data for both men and women. In the New York Life Insurance Company efforts have been going on for many years to determine the exact influence of build on longevity and Rogers thinks that these efforts are nearer the solution of the problem than ever before. A sketch is given which presents in perspective the mortality to be expected by reason of build alone irrespective of any other factor. It is suggested from a consideration of the sketch that a mistake has been made in assuming that the average build at any age is the most favorable build at that age or the build from which it may be expected the most favorable mortality will be sustained. For instance, the sketch shows that at the age of twenty all risks from 24 per cent. overweight to 10 per cent. underweight are better than average risks. Does it not then seem probable that the point of most favorable build is about half way from 24 per cent. overweight to 10 per cent. underweight or in the neighborhood of 7 per cent. overweight? If this inference is correct the tables now used are too favorable to underweights by about 7 per cent. At age sixty, on the other hand, the super-standard risks begin at about 8 per cent. overweight and extend to about 22 per cent. underweight. The mean point between these extremes lies at about 7 per cent. underweight and the conclusion appears evident that the present table based on average weights is too high by about 7 per cent. At the intermediate ages, thirty to fifty, the mean point lies not at the zero, but on the heavy-weight side of the zero at the age of 30 and at the light-weight side of the zero at the age of 50, and only at the age of 40 is the table apparently correct. Attention is also drawn to the probable inaccuracy of the table as regards the relative weights at the same height in age group 35-39 of men and women.—*Twenty-first Annual Meeting of the Association of Life Insurance Directors.*

Wisconsin to Undertake Business of Life Insurance.—A law has recently been enacted in Wisconsin authorizing the State to engage in the annuity and life insurance business after next year. The business is to be carried on under the management of the State insurance commissioner and is to be conducted on the same lines as a mutual insurance corporation, but at an expense not to exceed $2 per $1,000 insurance. Premiums are to be calculated according to the American mortality table. Annuities are to range from $100 to $300 and life insurance policies from $500 to $3,000.

Book Reviews.

Hand Book of Electrotherapeutics. By William James Dugan, M.D., Lecturer on Electrotherapeutics at Jefferson Medical College, Philadelphia; Physician-in-Charge at the Electrotherapeutic Department and Assistant in the Out-Patient Neurological Department of Jefferson Hospital; Fellow of the American Electrotherapeutic Association. With 91 illustrations. Price, $2.00. Philadelphia: F. A. Davis Company, 1910.

This is a compact little volume that is intended for students and practitioners who know little or nothing about electricity and electrical apparatus. It tells one how to select electrical apparatus, how to use the apparatus after it has been purchased, when to use electricity in medicine and when not to use it. There is an omission of a great part of the theoretical detail that makes most books on this subject quite cumbersome. It is strikingly clear and concise and may be recommended as a practical working manual. There are in addition to the excellent chapters on the various modalities of electricity, chapters on electrolysis, cataphoresis, electricity in surgery, high-frequency currents, the therapeutic uses of magnetism, vibratory massage, light and heat theraphy, and an appendix on death by electricity and on resuscitation of persons shocked by electricity.

Principles of Therapeutics. By A. Manquat, National Correspondent to the Académie de Médecine. Translated by M. Simbad Gabriel, M.D. Price, $3.00. New York and London: D. Appleton & Company, 1910.

The study of the fundamental principles of therapeutics is one which has been strangely neglected by both medical teachers and authors. The subject has been encumbered with a mass of heterogeneous facts and theories, so that scientific truth, empiricism, and fancy have been woven into a most peculiar fabric. It is for this reason that the therapeutic art has practically fallen into an undeserved disrepute. The time has come when this important branch of medicine should be rehabilitated to its important rank. The aim of this book is to assist in bringing about this renaissance in therapeutics. It makes a plea for a more intensive study of the subject and for a greater precision in its practice. It is directed primarily to young physicians, yet it is hardly likely that these will appreciate as fully as those who have had considerable experience the great philosophic truths that permeate the pages of this book. The author emphasizes the important fact that therapeutic actions are to be distinguished from so-called physiologic actions, which are often toxic. In classifying therapeutic measures the author refers to four different objects that these may attain: (1) Nosocratic therapeutics, which designates the medicaments which attack the cause of disease; (2) organic and functional therapeutics; (3) symptomatic therapeutics, and (4) reparative therapeutics. In the chapter on the action of medicines the author analyzes closely the subjects of toxic, physiological and therapeutic actions. The latter two are not synonymous terms: therapeutic action is often independent of physiological action. Therapeutic action may profit by a toxic action, as in the case of anesthesia. The question of pharmacotoxinic action is alluded to, namely, the action of medicines on intoxicated organs. Thus pharmacotoxinic synergy is exemplified in the administration of strychnine to a tetanic person, or chloral in uremic coma. The author emphasizes the possibility of doing harm through the addition of medicinal to morbid toxicity. In the chapter on medicinal opportunity it is noted that except in the case of specific medicines which, as a rule require fairly large doses, there is in the majority of cases advantage only in prescribing small doses; that is, doses considerably smaller than those usually recommended by formularies and treatises on therapeutics. The duration of medicinal prescriptions, the alternation of medicines, polypharmacy, and oligopharmacy, are all lucidly discussed. The chapter entitled *Primum non nocere* deserves careful reading. In the chapter on therapeutic individualization there are discussed the bearing upon therapeutics of sex, age, temperament, constitution, diatheses, and cachectic conditions; the patient, his organs, and functions; the disease; and the different modes of reaction of patients in regard to medicines. There is an excellent chapter on the influence of environment in therapeutic results; the influence of temperature, light, and color, climate and season, ventilation, furniture, the *entourage*, the nurse, the physician, consultations and change of physician, the pharmacist, and the priest. In the chapter on the variations of therapeutic activity inherent in medicines, and their mode of administration, there are discussed the causes of variations, physical properties and ionic dissociation, chemical structure, active principles, specialties, subcutaneous and intravenous injection, and fractional dosage and alternation. The succeeding chapters deal with nonmedicinal therapeutic actions, method in therapeutics, and the division of therapeutic agents. It is impossible within this brief survey to adequately convey the deep insight into his subject matter which the author manifests, and one can readily agree with him in the statement contained in the preface that "this book represents a far more considerable amount of labor than its size would suggest." The importance of the principles dwelt upon requires slow and careful reading, which cannot fail to benefit both student and experienced practitioner.

Primer of Hygiene. By John W. Ritchie, Professor of Biology, College of William and Mary, Virginia, and Joseph S. Caldwell, Professor of Biology, George Peabody College for Teachers, Tennessee. Illustrated by Karl Hassmann and Hermann Heyer. Price, 40 cents. Yonkers-on-Hudson, New York: World Book Company, 1910.

The writers of this hygiene primer have evidently spared no pains to make the text interesting and practical. The object in view is the education of school children along the lines of health preservation. The subject of foods is treated from several standpoints, including the cooking of foods. The digestive, nervous, and respiratory systems are discussed, one chapter being devoted to adenoids and enlarged tonsils. Information concerning the effects of alcohol and tobacco on the body; accidents, disease germs, simple exercises for use in schools, the skin, the eyes, and the ear, is presented in a form that must appeal to the mind of the child. The book is fully illustrated.

Pellagra. By Dr. A. Marie, Physician to the Asylums, Department of the Seine, Editor in Chief, Archives de Neurologie, and Director of the Laboratory of Pathological Psychology, École des Hautes Études, Paris, France. With Introductory Notes by Prof. Lombroso. Authorized translation from the French, by C. H. Lavinder, M.D., Passed Assistant Surgeon, U. S. Public Health and Marine Hospital Service; and J. W. Babcock, M.D., Physician and Superintendent, State Hospital for the Insane, Columbia, S. C. With additions, illustrations, bibliography, and appendices. Price, $2.50. Columbia, S. C.: The State Co., 1910.

This work is timely, for pellagra presents a problem which is of pressing interest to the physician, the scientist, the sanitarian, the political economist, and the legislator. Much interest has already been aroused in this subject, and the present volume is the first to discuss the matter in anything like a complete way. As will be seen from the title page, the book is practically a translation of Marie's work on the subject; but the translators have done more than give a rendering of the great Frenchman's book; they have added numerous notes, and a whole chapter, besides incorporating a bibliography so complete that the present volume will be necessary to future writers and investigators. The translation is well done, and where important features were omitted in the original, the translators have made the necessary additions. The bibliography alone occupies thirty pages, and there is a complete index, both of authors and of subjects. To all who are interested in pellagra this valuable monograph is commended.

Practical Bacteriology, Blood Work, and Animal Parasitology. Including Bacteriological Keys, Zoological Tables, and Explanatory Clinical Notes. By E. R. Stitt, A.B., Ph.G., M.D., Surgeon U. S. Navy, Graduate London School of Tropical Medicine, Associate Professor of Medical Zoology Philippine Medical School, formerly Instructor in Bacteriology and Tropical Medicine, U. S. Naval Medical School, and Lecturer in Tropical Medicine, Jefferson Medical College. Second Edition, revised and enlarged; with 91 illustrations. Price, $1.50. Philadelphia: P. Blakiston's Son & Co., 1910.

The merit of this volume lies chiefly in its compactness and the inclusion of all the data essential in a working manual. In this respect it has a certain advantage over accuracy and the saving of time. The section on clinical diagnosis, although these have their distinct sphere of usefulness as works of reference. In spite of its small size it contains all of the recent methods of laboratory investigation, including the determination of the Wassermann reaction, and the opsonic index, and the preparation of vaccines. There is given a method of making differential counts in the same preparation as that for making the leucocyte count, a method which has the advantage of accuracy and the saving of time. The section on clinical bacteriology and animal parasitology of the various body fluids and organs gives a concise practical statement as to how to proceed in the examination of various secretions and excretions.

Society Reports

CONNECTICUT STATE MEDICAL SOCIETY.

One Hundred and Nineteenth Annual Meeting, Held in Hartford, May 24 and 25, 1911.

(*Concluded from page 56.*)

DR. FRANK K. HALLOCK OF CROMWELL, PRESIDENT, IN THE CHAIR.

Some Aspects of the Early Months of Pregnancy.—Dr. JOHN B. M'COOK of Hartford said that these "poor registers," as they might be termed, might be divided into five groups, although many cases showed the imperfections of the nomenclature by belonging to several groups. The examinations should be rigid and thorough; but whatever was done in the way of examination must not be such as to frighten the patients or to set up in them a train of thought that might end in a pathological mental state. The obstetrician should not create trouble, yet it would be found that one of a lively imagination was a safer guide than an unimaginative man.

Dr. THOMAS W. CHESTER of Hartford said that the examination should be made in rather an off-hand way; or, at least, the patient should think it off-hand, because such women were easily frightened. He did not, however, think that a very rigid examination was often required. If a young woman appeared normal, felt well, and had a good family history, he thought that the doctor might rest satisfied, if the examination revealed normal heart, lungs, kidneys, bowels, and pelvis, simply instructing the patient to report once in two weeks or oftener if anything went wrong. Other cases, however, required a more thorough examination. He dreaded particularly two types, the short, thick-set women, with perhaps perfectly normal measurements of the pelvis, and the young, athletic girls.

Some Problems Connected with the Inspection of Schools.—Dr. EDWARD W. GOODENOUGH of Waterbury stated that the most important work of medical men at the present time was connected with the growth and development of the child. Medical inspection of schools was primarily for the benefit of the growing child. Physicians should not be appointed as medical inspectors simply because of their political affiliations, and the town or the State should be willing to pay members of the medical profession a reasonable amount in order to give the children in the schools protection against disease. This was not a charity; it simply gave an added force to the development of democracy. A school nurse the author also considered a necessity, as she could help the physician in many ways. He thought, however, that until the position of medical inspector of schools was fixed on a firm basis in this State physicians appointed to that office should be willing to give the town more than a full equivalent for the money invested in this work.

Dr. CHARLES P. BOTSFORD stated that, in attending the hearings of the Legislative Committee on bills concerning the medical inspection of schools, he had been struck with the amount of opposition that had seemed to develop, not so much against the particular bill under discussion at the time, but against the whole subject. He considered it a duty that physicians owed to the rising generation to try to influence the fathers and mothers in favor of medical inspection, and to convince them that this was not necessarily very expensive. A properly devised medical inspection, suited to the town and the school in which it was used, would, he said, pay for itself in the more regular attendance and better work on the part of the children. Each town, and perhaps each school district, must develop the work along different lines. He mentioned a number of questions that would have to be settled before medical inspection could be brought to a definite, uniform basis. One was in regard to the frequency of the examinations and the amount of time that it was justifiable to take for this purpose from the already crowded curriculum. Another was that of getting the recommendations made by the medical inspector carried out. He thought that the logical thing would be for the State to give the school authorities the power to demand the correction of defects that interfered with the child's progress in school, but said that it was a question whether public opinion would support such a proceeding.

Dr. FRANK H. BARNES of Stamford stated that a member of the Legislative Committee of Public Health and Safety who was a physician had told him that he was in favor of the medical inspection of schools, but that there was such a drift of public opinion against it that he was afraid such a bill could not be passed. Dr. Barnes thought that the members of the State Medical Society should get together, introduce one bill, and try to get it passed, as there were more feeble-minded children, idiots, and imbeciles in the schools than one would think. He believed that it would be better not to include the small country towns, and said that the question whether the school committee or the public health boards should take charge of the inspection should be decided.

Dr. THOMAS S. SLOAN of Manchester referred to a serious and long-lasting epidemic of diphtheria and scarlet fever that had occurred during the past year, and stated that throughout this time every child's throat had been examined twice a week. Cultures were made from such throats as were found inflamed. In this way, some children with diphtheria were discovered and sent home. When necessary the school-room was fumigated. Medical inspection had been in operation for two years in Manchester, and the people were well satisfied with its results.

Dr. EDWARD K. ROOT of Hartford remarked that the general public, knowingly or unknowingly, made a sharp distinction between contagious diseases, in which their children's lives might be endangered through coming into contact with children that were ill, and conditions of malnutrition and degeneracy, which they regarded as no one's business but their own. In Hartford, where medical inspection had been in existence ten years, the treatment of any sick children discovered was always turned over to their parents. If they were not taken care of at home, then the town had to attend to the matter. It should be remembered, however, that everything that the State did for the child lessened the responsibility of the parents to just that extent.

Dr. HENRY F. STOLL of Hartford had been impressed with the fact that the teachers were not capable of picking out delicate children. He had tried at first to get them to send to him cases suitable for the out-of-doors school. Finally, he adopted the plan of standing at the foot of the stairs when the children were dismissed, so that he could see them in a good light when walking. He could then select the children that he wished sent to him for a more thorough examination. He thought that there was no doubt that the physicians could educate the public, but said that most of them had not realized their duty in that respect.

Dr. KATE C. MEADE of Middletown asked whether the teachers in Waterbury examined the children's eyes, and whether there was a dental clinic at which the children's teeth might be examined.

Dr. WILLIAM H. DONALDSON of Fairfield asked Dr. Barnes why he would not include the smaller towns.

Dr. BARNES answered that it was because many of the smaller towns do not have a physician at all, and would have to get a doctor from the outside to examine the children. This would put them to great expense.

Dr. SAMUEL M. GARLICK of Bridgeport believed that

referring the matter back to the parent would educate the parent and the child itself. It was much more desirable, he thought, to educate the individual than to educate the public. To dismiss the matter without reference to the family physician tended to reduce the confidence in the latter that the family should have.

Dr. George H. Wright of New Milford remarked that in almost every case the parents could be perfectly educated, not only to submit to the inspection, but to carry out the recommendations made by the inspector. The news of the good results obtained would be spread among all classes of society. He thought that the educational effect of simply making good was wonderful, and that this was a better way to make progress than simply by compulsion.

Dr. Sloan said that if the school physician and the school nurse, with some operator, could attend to the matter, they would be likely to lose the cooperation of the family physician. For that reason, he thought that it was better to refer the patients to the family physician.

Dr. Goodrich said that in some of the schools the teachers examined the children's eyes, and that in others they did not. There was no free clinic for dental work in Waterbury. In some ways he considered that town pretty healthy; yet the more he went among children the more he felt the need of medical inspection, not simply to discover cases of contagious disease, but also to find other cases of extreme conditions, such as mouth-breathing. He believed that if school inspection was to be secured work must be done that would impress the parents.

Bronzed Diabetes; Report of a Case and Review of the Literature.—Dr. George Blumer of New Haven said that the case showed the triad of symptoms and signs that characterized typical examples of bronzed diabetes. The form of diabetes associated with this condition was usually acute. The skin pigmentation, which was entirely lacking in about one-sixth of the cases, varied greatly in both color and situation. In many of the reported cases disease of the liver was present years before the appearance of the other manifestations. Some patients entered the hospital with gastrointestinal disturbances. The occasional occurrence of the clinical evidences of blood destruction might be noted. This disease was confined almost exclusively to males, generally between the ages of thirty and sixty years. He said that alcohol played an important part in the etiology of many of these cases. A large amount of iron was present in some of the organs, as well as in the skin lesions. The blood destruction which took place within the portal zone might lead to the deposit of pigment. The maximum deposit was in the abdominal organs, and was much like that which occurred in hemochromatosis. He considered that the differential diagnosis might be simplified by pointing out that a combination of pigment with an enlarged, hard liver and glycosuria was not liable to occur in any other condition. He admitted that the possibility of the occurrence of diabetes or of an enlarged liver as a complication of various diseases associated with pigmentation of the skin could not be denied, but said that it was unlikely that this triad of symptoms and signs would occur outside of bronzed diabetes.

Dr. Wilder Tileston of New Haven said that the name hemochromatosis was preferable to bronzed diabetes, because it covered cases of pigmentation of the skin without any signs of diabetes. In 1889 he had seen such a case in Boston. The patient looked like a mulatto, though his skin had been fair before his illness. He showed no enlargement of the liver and no sugar in the urine. Microscopic inspection showed the presence of iron pigment, which did not occur in any other condition than hemochromatosis; although its absence did not exclude that diagnosis. He though that the coloring matter was probably brought to the cells by the blood, and not manufactured locally by the skin. Pigmentation of the skin had usually been considered as indicative of Addison's disease, but he had found only the minority of the cases to be due to affection of the adrenals. He stated that the pigmentation of arsenic, though rather uncommon, should be borne in mind in this connection. It was possible to have a pigmentation of the mucous membrane of the mouth in people otherwise healthy.

Parotitis.—Dr. Fritz C. Hyde of Greenwich said that secondary parotiditis was usually an infection of the parotid gland via Stenson's duct. Sympathetic or reflex influence from the generative and other organs was a factor in its production only as it caused, in common with other similar processes, vasoconstriction of the parotid blood-vessels and inhibition of secretion. Dehydration of the body from any cause was a predisposing factor. Secondary parotiditis was usually a condition of adult life, and most commonly occurred as a sequel to infectious fevers; following various operations, particularly of the genital organs; and in various conditions such as uremia, lead-poisoning, etc. It was of wide distribution in diseased states. The salient points in the production of the contagion were the ever-present potential infection from the mouth and those phenomena that induced a decreased or abolished flow of saliva into the efferent duct. In its prevention, the nearest approach to a clean mouth was important, the essential point being to secure free discharge of the saliva at all times. In operations, dehydration of the body must be lessened by reducing to a minimum hemorrhage, shock, cathartics, vomiting, sweating, starvation, and the use of morphine and atropine. In the differential diagnosis, the difficulty lay in eliminating epidemic parotiditis, or mumps. The latter was usually bilateral, and the flow of saliva but slightly affected, while in secondary parotiditis it was greatly lessened or abolished. The latter was usually readily traceable to the initiative condition. Suppuration was common in secondary parotiditis, but did not occur in mumps.

Dr. Rush W. Kinball of Norwich stated that different authorities held different views as to the cause of the condition and the means of infection. He considered the best working hypothesis to be that in the majority of cases it was through Stenson's duct. His own personal experience with secondary parotiditis was limited to four private cases. In the treatment, he emphasized the importance of regular oral hygiene and, in suppurative cases, of making an early incision and drainage. As the abscesses were deep-seated in the fascia, fluctuation was seldom obtained.

Dr. George Blumer of New Haven pointed out the tremendous reduction in the prevalence of secondary parotiditis in such a disease as typhoid fever since trained nurses had been in use. He considered this favorable to the view that it was an ascending infection through Steno's duct. He said that with very sick patients there was a decrease in the general resistance to bacteria. Inhibition of the flow of saliva was not always a factor, because in the disease called dry mouth there was no parotiditis whatever.

Dr. Hyde stated that there was on record a case of dry mouth with suppurative parotitis that required incision.

President's Address: Law, Medicine, and the State; Some Points of Contact.—Dr. Frank K. Hallock of Cromwell said that the members of the professions were, in the main, the recognized exponents of the best thought and the most worthy ideals; and that, as such, the great mass of the people who were less favored in education had a right to look to them as the natural leaders in the solution of civic problems, moral and physical. Independent effort could not be so successful as the effort that had back of it an organized body or class. Such organizations in the professions should have at least two ob-

jects: to raise the standard of their own efficiency, and to discharge their duty to the State by accomplishing results calculated to benefit the general public. The County and State Bar Association had lamentably failed to arouse themselves to active work in these directions, but it must also be admitted that the shortcomings of the medical profession were legion. The two professions should get together for the benefit of the State on such points of contact as expert testimony and boards of health; and the State Medical Society should request the State Bar Association to appoint a permanent committee on medical legislation, to meet in joint conference with the Medical Society's Committee on Public Policy and Legislation and formulate plans for concerted action on all matters of mutual interest to the legal and medical professions. The State Medical Society should also invite representatives of all organizations of allied interests to meet with them and consider some concerted action on matters pertaining to the life, health, and sanitary condition of the citizens of the State.

The Importance of Early Operation for Tumors of the Breast.—Dr. George N. Bell of Hartford stated that the situation in regard to breast tumors had not changed much in the past century. If their benignancy was absolutely assured, they should be let alone; but if malignant, they should be removed. The treatment depended altogether upon the ability to decide which was which. Eighty per cent. of all breast tumors being malignant, the need of early diagnosis, and operation in cases of malignancy, was apparent. As the operative mortality was less than 1 per cent., it was a wonder that the postponement of an operation in these cases was still considered. Multiple tumors of the breast were usually benign, but the one positive means of diagnosis was the microscope. One could not, however, be sure that a benign tumor would remain benign. Therefore, it was best to remove a mass in the breast as soon as attention was called to it, submit it to the pathologist for diagnosis, and then, if necessary, operate radically. Next to the extent of the growth, the chief factor in the prognosis was the glandular involvement. The more radical methods of operating, consisting in the removal of both muscles and axillary contents, together with greater rapidity in operating, had given much better results that those formerly obtained. Another recent advance had been in the use of frozen sections in doubtful cases.

Dr. Oliver C. Smith of Hartford remarked that the cancer problem had not yet been solved, although the limits of improved technique had probably been almost reached. He thought, however, that surgeons were not sufficiently mindful of the fact that cancer tissue could be disseminated. More care should be used to prevent this in operating, and the position of the patient was also very important. If a means of early diagnosis could be discovered, the technique could be used at a time when it would be more beneficial. Since the frozen sections had come into use it was easier to get patients to submit to operation with the promise that the breast would not be removed if the tumor were found to be nonmalignant. One could not, however, always tell at operation whether one was dealing with benignancy or malignancy. Physicians should try to educate the public to realize that a tumor of the breast was a dangerous thing, and should be investigated at once by a competent person.

Dr. Carmalt remarked that though in former times they judged by empirical rules, while physicians now speak from a pathological standpoint, the practice had not changed. One could never tell a benignant tumor from a malignant one; and a benignant tumor was likely at any time to become malignant. A cyst with a lining of epithelium was liable to become a cancerous growth from the capsule, rather than from the cyst itself. He thought that more harm had been done in attempting to treat cancer of the breast by means of the *x*-rays than all the good that had ever been done by them, and he was not very enthusiastic in regard to diagnosis by means of the microscope. The little snip of the growth usually submitted to the pathologist might have nothing malignant in it, yet the tumor might be cancerous in other places. He considered the three years' limit too small to enable one to be sure that the case was cured. In operating for cancer of the breast, he thought it best to begin in the axilla. If this could not be thoroughly cleaned out, it was not worth while to go further.

Dr. Charles E. Taft of Hartford emphasized the importance of examining all the organs of the body liable to metastasis before deciding to operate upon a cancer of the breast. It was his custom, after the muscles had been dissected away, to tie with a needle and thread all the small blood-vessels in the chest, in order to prevent secondary hemorrhage. Unless a physician was himself prepared to urge a patient to submit to operation, he should immediately refer all tumors of the breast to a surgeon.

Dr. Seldom B. Overlock of Pomfret said that in a young woman with a loose tumor of the breast one could often merely take out a triangular section, without destroying the contour of the breast. If further involvement afterward occurred, the purely radical operation should be done.

Dr. Clarence E. Skinner of New Haven admitted that early and thorough ablation was the first and most important step to be taken in the great majority of cases of tumors of the breast, but thought that, in order to prevent recurrence, röntgenization should be employed immediately after every ablative procedure for cancer. He stated that the *x*-ray exhibited a powerfully curative influence over malignant processes in many cases, and believed that in a disease with such a gloomy prognosis it was not justifiable to omit the application of any means of control that had demonstrated that it possessed value. It was impossible to tell at the time of operation in which cases recurrence would take place, and recurrence was frequently more resistant to the *x*-ray than the original lesion. Early recurrences also were frequently internal, giving no sign until it was useless to do anything.

Dr. Bell thought that if the tumor of the breast felt malignant when operating one should go on with the operation, even though a report of benignancy were obtained from the pathologist; because the latter might have received a piece with no malignancy in it, even though the remainder of the tumor was malignant. When, however, the growth was almost unquestionably benign, there was no necessity of removing the entire breast. Personally, he did not believe the *x*-ray to be of value either before or after the operation; but he saw no reason for denying its use to a patient who wanted to try it.

Intestinal Obstruction with Reference to Intussusception in Infants.—Dr. Owen O'Neil of Willimantic, from a consideration of three cases that might be taken as fairly representative of those encountered by him, deduced the necessity of early recognition, to which the palpation of a sausage-shaped tumor through the abdominal wall was by no means an unfailing guide; that vomiting, though fairly constant in acute intussusception, might not be present; the value of prompt operation, limited to the relief of the actual acute condition; the uselessness and even danger of palliative measures, which might ameliorate the active symptoms of the disorder and even simulate true reduction, thereby causing serious delay in the institution of radical treatment; the unfavorable results of attempting to return these children to the maternal breast, the nervous strain of the mother being almost certain to disturb lactation; and that mechanical obstruction by a foreign body in the intestines might present all the general symptoms of an intussusception.

Dr. Joseph M. Flint of New Haven said that in both the cases of true intussusception mentioned by Dr. O'Neil there had been an absence of the clinical symptoms of abdominal tumor. Acute abdominal symptoms, mucohemorrhagic stools, and a palpable tumor in the rectum were the most common signs of intussuception in young children. He thought that palliative treatment deserved a wider recognition in a group of cases in which the intussusception might not be reducible, and in which an extensive gangrenous process might be present, with relatively little symptoms on the part of the infant, and no general reaction indicated by signs. However, the operative method should be applied as early as possible, because no one could tell when palliative measures would lead to serious results.

Dr. John W. Wright of Bridgeport said that some years ago he had been called into consultation on two cases that were undoubtedly intestinal intussusception, but that he then mistook for cases of mild enterocolitis. The diagnosis not being complete enough to warrant operation, both children died. He had found intussusceptions at post-mortem examinations—in one case, as many as twelve. Within the last few years he had seen no cases of enterocolitis in children resulting in intussusception. Therefore, he had not operated on that sort of case. He warned those present to be more observant of the symptoms exhibited in infancy, so as to avoid the error that he had confessed to, of not being sufficiently accurate in the diagnosis.

Dr. James H. Kingman of Middletown spoke of a case of intussusception showing that one should not do too much at once in this work. He had found five inches of black, gangrenous gut, which, as the child's condition was very bad, it was deemed unwise to resect. The gut was therefore stitched around, and an artificial anus made. After this, the child did very well, and most of the gangrenous part of the bowel finally sloughed off, leaving the double ends projecting out of the abdomen. These were clamped, and motions were obtained through the regular route. A few months later, a resection was done, with a perfect result. He believed that the child's life had been saved by doing no more at the first operation than to make an artificial anus.

Dr. Taft thought that one statement in the paper should be challenged. This was that all cases should be operated on without resorting to palliative measures. He considered it first essential to make a diagnosis of the location of the intussusception. In one case of very recent occurrence he had been able to replace the intussusception inside the rectum. Then, by inverting the child and employing hydrostatic pressure and careful manipulation of the abdomen, immediate relief was secured. He thought that the fact that the intussusception might subsequently return was no argument against making use of such palliative measures in cases of that kind.

Dr. John B. Boucher of Hartford stated that some years ago he had had the accident of reinvagination happen in one of these cases. In order to prevent this in a subsequent case, he had dissected off the mesentery, bringing the cecum down to the abdominal wall at the point where it should have been, and had drawn the appendix through the tendon, putting a piece of adhesive plaster over the appendix and leaving it there for twenty-four hours. He then cut it off, obtaining primary union.

Dr. Harmon G. Howe of Hartford said that one should not be too energetic in one's work with the hydrostatic method, nor trust to the apparent recentness of the attack; because some of these cases had been partially invaginated for some time before presenting symptoms. Even if one did by this means succeed in reducing the intussusception, death would sometimes take place from gangrene.

Dr. Edward W. Smith of Meriden stated that in a case of intussusception of the ileocolic variety in a child of eleven months, two or three inches of the cecum had been drawn in. The patient was operated on, and made a good recovery. Six months later it had another invagination, probably due to having eaten a large amount of peanut candy. This time he employed Dr. Taft's method of inverting the child and manipulating the bowel. The tumor disappeared, and the infant dropped into a quiet sleep.

Dr. O. C. Smith thought that he would be inclined first to try palliative measures, because in a child this was a serious operation. The use of warm sweet-oil might carry the intussusception up, even though it was not quite undone. This would show the region the intussusception started from and give an idea where to operate.

Dr. Overlock said that, while good results were exceptionally produced by palliative measures, the fact remained that a high percentage of these patients would have died if not operated upon.

Dr. O'Neil said that to attempt palliative measures under anesthesia seemed to him to be subjecting the infants to too much medicine. He thought that once was enough to give a baby an anesthetic, because this was very depressing. One should attempt any palliative measures employed under anesthesia, and be ready, in case of failure, to go ahead with an operation.

Peritoneal Tuberculosis.—Dr. Daniel Sullivan of New London said that tuberculous peritonitis would mimic every other abdominal disease or condition. It was secondary to tuberculosis in some other organ in 90 per cent. of the cases, the lungs being the primary seat more frequently than all the other organs taken together. He had had two cases in which jaundice was a pronounced symptom. While peritoneal tuberculosis was sometimes a surgical disease, it was always a medical one. The medical man should treat these patients with rest, fresh air, nutritious food, medicine (if necessary to help the emunctories), and all that goes with good nursing. If, after five or six days, there was no improvement, and the case was one of the ascitic form; or when the Fallopian tubes or the appendix appeared to be the location of the mass—a laparotomy should be advised. Simple incision and the evacuation of the fluid, with removal of the primary seat of infection, if possible was the best procedure, the wound being closed without drainage. Then one should again begin with the hygienic treatment.

Dr. John B. Boucher of Hartford said he believed that, like septic peritonitis, tuberculous peritonitis was due to a local infection in every case. This surgeons were finding to be so. It was three or four times more common in women than in men, the Fallopian tube, next to the tonsil and the lung, being the most susceptible organ to tuberculous infection. Abdominal drainage should not be used, because mixed infection should be avoided in such cases. If this was prevented, tuberculosis was a comparatively harmless disease.

Dr. Overlock thought that most of the statistics showing this condition to be found more often in females than in males were due to the existence of avenues of infection in the former not found in the latter. Tuberculous peritonitis was frequently found at operation in cases in which some other lesion had been suspected. The diagnosis, while very important, was difficult, on account of the fact that this condition simulated so many other things. One was not justified in jumping at the conclusion that a patient's peritonitis was tuberculous because there was tuberculosis present in some other organ; for, even in such a case, the process in the peritoneum might be an acute one. The medical treat-

ment in these cases consisted in putting the patient into the most favorable condition to resist the disease. The surgical treatment could be of service in eliminating the foci of infection and covering them up; as much tuberculous material as possible could thus be gotten rid of, leaving nature to pour out an effusion and help bury what was left.

Dr. David R. Lyman of Wallingford said that he had usually referred these patients to the surgeon because of acute appendicitis; but that back of this there had been the tuberculous peritonitis. In several cases he had seen bad effects from ether anesthesia, and he was inclined to be very cautious in its use in patients with tuberculous peritonitis. He believed the medical part of the treatment of such cases to be a great factor in conjunction with the surgical.

Dr. Edward R. Lampson of Hartford said that his brother-in-law, who had had tuberculosis of the lung for fifteen years, was operated upon for appendicitis under stovaine, in the Presbyterian Hospital, by Dr. Blake. The operation was entirely successful, and the patient regained the weight that he had lost as the result of the appendicitis. Dr. Lampson thought that when the involvement was not great chloroform or gas should be used; but that when any general anesthetic was contraindicated, as in this case, stovaine might be employed as the last resort.

Dr. James J. Boucher had seen a large series of cases of the ascitic variety of tuberculous peritonitis. He explained that in women the hydrostatic pressure of the fluid in the abdominal cavity kept the Fallopian tubes open, allowing the entrance of tuberculous material. Withdrawing the fluid caused the condition to become merely a localized salpingitis; and the peritoneum was then able to overwhelm the bacilli remaining in it. In tuberculous peritonitis without involvement of the lungs he considered ether to be a safe anesthetic, but said that it was dangerous when the lungs were involved. In cases in which chloroform had been used more or less destruction of all the internal organs had been found; while with ether there had been practically no change.

Dr. Sullivan stated that the tonsils and the ears were frequently the avenues of entrance of the tubercle bacilli into the system; and that when the lung was involved there was a change in the lymphatic glands. Though both the glands and the lung might have healed, the bacteria might still be lying dormant in the body, only to wake up and infect the peritoneum later. This was the explanation of many cases of primary tuberculous peritonitis. Dr. Sullivan said that a good many cases of this were sent to the surgeon in the belief that they would be surely relieved. He thought that the surgeon should protect himself by making certain that the lungs were not involved.

The Two-Stage Operation for Intestinal Obstruction.—Dr. Edward R. Whittemore of New Haven said that the mortality of operations for acute intestinal obstruction was so high that there was great need of improvement. The condition of these patients was usually toxic, and there was danger of increasing this toxemia by removing the obstruction without instituting drainage of the bowel, especially in the upper intestine. He had, therefore, found it advisable to do a simple enterostomy at first, leaving the removal of the obstruction until later. The operation should be done as early as possible, with the usual preparation of the patient, especially remembering to wash out the stomach before giving the ether. Only the briefest examination should be made at the time of operation to discover the site and cause of the obstruction, the search being abandoned if not soon successful. A simple enterostomy should then be done on the most distant loop, preferably not in the median line. If any gangrenous gut was seen, it should be drawn into the wound, secured there, and opened. All other procedures should be left until the second stage, a week or so later, when the patient would be better able to stand operation. The object of this procedure was, first, rapid and efficient drainage of the bowel, the relief of the obstruction being a secondary matter, to be taken up later.

Dr. Everett J. McKnight of Hartford considered it important to realize that above the point of obstruction there was a large amount of toxic material, which, if allowed to go down through the gut, might be absorbed and cause trouble. In intestinal obstruction one should not, as a rule, close up the bowel in the abdomen without having taken due precaution against this source of intoxication. He called attention to the advisability of doing an enterostomy also in many cases of postoperative distention, when this could not be relieved by any other means.

Dr. Whittemore stated that in one of his cases the operation had been followed by a rise of temperature for a few hours, and that this might be attributed to the passage of the toxins on below the point of obstruction.

Election of Officers.—The officers elected for the ensuing years were as follows: *President*, Dr. John G. Stanton of New London; *Vice-Presidents*, Drs. D. Chester Brown of Danbury and Robert C. Paine of Thompson; *Secretary*, Dr. Walter R. Steiner of Hartford; *Treasurer*, Dr. Joseph H. Townsend of New Haven.

The Society will hold its next annual meeting at New Haven on the fourth Wednesday and Thursday of May, 1912.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Held May 22, 1911.

The President, Dr. James F. McKernon, in the Chair.

The Fatalities of Delay in the Diagnosis and Treatment of Rectal Diseases.—Dr. James P. Tuttle read this paper. Unlike constitutional diseases, those of the rectum had no tendency to spontaneous healing; they were nearly all infectious, and the infection was always present. If the profession and laiety could be brought to attach due weight and importance to the minor rectal symptoms and to seek and receive the proper examination and treatment early in these conditions there would be very few serious cases and rarely a fatal one; very few of them would require anything more than a slight operation. Dr. Tuttle proposed to cite some parallel cases showing on the one hand the fatalities of delayed diagnosis and neglected treatment and, on the other, the happy results in similar cases recognized early and treated properly before any serious symptoms developed. Thrombotic hemorrhoids was a condition often ignored, and yet capable of producing the most disastrous results if not properly treated. Dr. Tuttle cited the case of a man who neglected this condition for only a few days, when the clot became infected, an abscess formed, extending halfway around the anal opening, and a condition of general sepsis followed, with a temperature of 104° F. It was a clear case of infection of the clot through one of the skin or sebaceous glands. It took five weeks for the infection to disappear and for the tract to heal. This was not an exceptional case. In apposition to this case Dr. Tuttle cited another in which the first symptoms were followed by the evacuation of clots. This gave immediate relief from pain and enabled the patient to attend to her usual duties. This was a daily experience and was what should occur in almost every case of thrombotic hemorrhoids if properly diagnosed and properly treated. Anal fissure in its earliest symptoms gave little or no pain and slight inconvenience, and was the most amenable of rectal diseases to treat, yet

if left unattended and allowed to become chronic it was capable of the most distressing results. It was now believed to be the initial lesion of all true fistulas, whether simple, compound, or complicated. If left until the wound became infected and the tract burrowed underneath the skin and mucous membrane, or until cicatricial deposits and perineuritis occurred, there was no condition that would give more distress or bring on more serious results. Fissues were the most nerve wrecking, irritating, and depressing of rectal diseases, and produced suffering out of all proportion to their duration and extent. They were all curable by local application or minor operation in the beginning. The majority of cases of simple hemorrhoids if taken early and treated properly could be aborted. Dr. Tuttle related a number of cases in which a foreign body had become imbedded in the rectum that showed the advisability of making a rectal examination when patients complained of rectal trouble. He also cited a case where an impacted fecal mass was neglected, or rather overlooked, and the results were most disastrous. The misleading point in such cases was the fact that the patient might complain of diarrhea This was caused by tenesmus and the increase in the fluids of the bowel which passed around the mass. The attending physician was likely to give a laxative and to suppose that he had obtained a free movement of the bowels. Examination with the finger would reveal the trouble and avoid serious consequences. Fistulas, Dr. Tuttle thought, could be averted if seen early enough. A large part of them originated in a small abrasion. The failure to discover the initial lesion was largely due to patients who belittled the minor symptoms, and a physician was not called until an abscess formed. The physician too often prescribed a poultice or salve and adopted a waiting course until the abscess reached the surface and broke of itself. A diagnosis should have been made and the abscess opened in the beginning. If such a course was pursued they would see few chronic fistulas. Perirectal abscesses or infections in the deep perirectal spaces were usually not due to rectal disease at all, but to prostatic, urethral, and uterine conditions; they not infrequently broke into the rectum or had been opened by surgeons into this organ, a most unsurgical and dangerous procedure. Early diagnosis and treatment of such conditions was most important, for they were really dangerous to life. The author had known deaths to occur from delayed surgical intervention Carcinoma was, the author assumed, a local disease in the beginning, and it was curable in the rectum by only one method—that of complete extirpation. When it had existed long enough to involve the perirectal organs, such as the sacrum, the prostate, the vagina, or the lymphatics, extirpation was almost impossible. If it was seen before such invasion had occurred the patient would have a fair chance of permanent recovery, or at least long freedom from the disease. Since his report of 100 cases of cancer of the rectum in 1908 Dr. Tuttle had seen 81 cases of this condition in private practice. Of this number 44 had been operated upon, and of the 37 remaining operation was refused in 4 cases on account of bad prognosis and 33 had been turned down as inoperable. Of these 37 cases the average time at which they first noticed symptoms before consulting the writer had been 14.6 months; most of them had been observed for from six to twelve months by their family physicians and treated for ulcerations, diarrhea, hemorrhoids, etc.; five had been operated on within six months for hemorrhoids, the carcinoma no doubt being present at the time. There was every evidence that had proper examination been made early enough the disease could have been discovered in nearly every case in time to have afforded the patient a reasonable chance by surgical intervention. In how many cases the delay was the fault of the patient and in how many the fault of the doctor the writer was unable to say, but the histories showed that most of them had been under treatment for from two to ten months before Dr. Tuttle saw them. In the forty-four cases operated upon only one case was lost among those who came to operation under ten months after the first symptoms appeared. Rectal and sigmoidal examination ought to be made a part in the routine practice of examination in stomachic and digestive disturbances The only way these conditions could be diagnosed was through digital and ocular examination. All constipations, every diarrhea, or tendency to diarrhea that lasted after a proper cathartic and irrigation of the rectum; all passages of mucus, especially of the glairy type; all loss of blood from the rectum; all persistent and increasing indigestion; all autointoxication demanded a careful proctoscopic examination. Where blood and glairy mucus seemed to come down from above the part at which the tube could be introduced an exploratory operation should not be hesitated upon. Dr. Tuttle exhibited a specimen which he said was a villous papilloma and related the history of the case from which the specimen was taken.

The Operation of Choice in Carcinoma of the Rectum.—Dr. Joseph A. Blake presented this paper. He stated that there were two methods of attacking malignant neoplasms of the rectum; the perineal, by which the growth was removed from below, and the abdominal, or the combined operation, by which both incisions were used. The later perineal operations had been much simplified by the discovery that the bowel could be readily loosened from below so that the end, after resection, could be easily brought down to the level of the anus, thereby eliminating the necessity of resecting the sacrum and coccyx. The necessity remained, however, of making a large wound in order to gain free access to the abdominal cavity from below. The abdominal method had been correspondingly improved. In discussing which one of these was the method of choice it was extremely difficult not to be biased in favor of one or the other. Eventually he thought they would reach the conclusion that both operations were good, and that the operation of choice was the one best fitted for the case in hand. The foremost thing to be accomplished in a given case was the complete eradication of the growth; a secondary but important consideration was the preservation of a normal functionating natural anus; lastly, but most vitally important, was the conservation of the patient's life. In regard to the first of these it was obvious that a radical operation should not be undertaken unless this could be accomplished. The chief objection to the perineal, and one of the chief arguments in favor of the abdominal, method was that in many instances this question could not be determined until the perineal operation was all but completed, while in the abdominal operation it was decided at the expense alone of the abdominal incision. Dr. Blake had in two cases found secondary neoplasms in the gut several inches above the main growth which would have been missed by the perineal operation. The abdominal method on the whole better fulfilled the condition of complete eradication, and the higher the growth the greater the indications for this method. In all growths necessitating the destruction of the sphincter it was preferable to institute a permanent inguinal anus and to extirpate the remainder of the rectum. Dr. Blake had done this in fourteen consecutive cases without mortality. This would be the operation of choice were it not for the artificial anus. It had a low mortality because there was no secondary infection, the fecal current being deflected from the site of operation. If the lower limit of growth was three inches or more from the anus, the gut could be divided below the growth through the abdominal incision and the operation completed without a perineal incision other than a stab drainage opening. In regard to the comparative mortality of the two methods.

of operation the perineal as a routine measure was the safer. The mortality of both was, however, high, and there was not as much difference as was generally supposed From his own experience the writer believed that the abdominal operation was cleaner and that there was not so much danger of sepsis as with the perineal operation. The combined operation was the most severe of all. It was not dangerous, however, if an inguinal anus was instituted at or before the operation. For low growths involving the anal canal so that the sphincter had to be sacrificed the combined abdomino-perineal operation with the formation of an inguinal anus was the operation of choice. For the ordinary low ampullary growths, when small, the perineal operation was indicated for both sexes; in the case of larger growths in women and in some men the combined method should be chosen. For growths lying about three inches from the anus or for those cases in which the bowel could be divided below the growth Dr Blake preferred the abdominal incision and the invagination of the upper segment through the lower with suture within the abdomen or without the anus by a modification of the method used by Maunsell and Wier. Dr. Blake described the ingenious method devised by Dr. Hugh Auchineloss for the anastomosis of the oral with the aboral segment in this operation. Thus far this method had not been used on the living subject, but it had been shown to be practicable upon the cadaver.

Dr. Samuel G. Gant said there were a few simple rules which doctors might follow in the diagnosis of rectal diseases; many mistakes were made by the internist in diagnosing rectal diseases. It was not necesary to make an apology to every peron who came to the doctor because it was necessary to make a rectal examination when the symptoms pointed to a diseased condition there. He did not advise the use of a finger eot. Every disease of the rectum could and should be diagnosed if the patient appeared early, but with the use of the proctoscope or sigmoidoscope. The most serious diseases of the rectum were not those that always caused pain. Ninety per cent. of all rectal dieases occurred within one inch of the anus; therefore, in making a rectal examination one should begin at the anal margin and work up carefully. The presence of pain was very indicative of some diseases; if this existed after a bowel action it was apt to be due to a fissure. The severer diseases, however, were indicated by diarrhea. Dr. Gant emphasized the importance of making a careful examination about the anus in making a diagnosis. About 50 per cent. of the cancer cases were inoperable when he saw them; this certainly was inexcusable The symptoms of carcinoma in the early stages were so slight as to make the diagnosis difficult; in the intermittent stage the diagnosis was easy; in the later stage the condition was practically self-diagnosed. There was a general impression that the odor, the pain and hemorrhage were the diagnostic symptoms of cancer; at the time these symptoms appeared the condition was probably an inoperable one. Odor, pain, and hemorrhage which occurred in the later stages of the disease indicated that the growth was inoperable. With regard to the Kraske operation, operators were getting away from it and employing other and better methods.

Dr. Samuel Lloyd said that the drift of the papers was early diagnosis and treatment; that was a principle needed in all surgery, not only in rectal diseases but in all other surgical diseases. The earlier one made the diagnosis, the less would there be for the surgeon to do. The human ostriches, those who had swallowed glass, pins, needles, nails, shot, and other foreign bodies were the ones that suffered from the injuries referred to. The question of carcinoma, of course, interested all. Dr. Lloyd did not agree with the point that odor, pain and hemorrhage indicated that it was too late for operation; many cases he had operated upon had done well. One case he had operated upon with these symptoms had lived sixteen years; a number of cases he had operated upon had lived from twelve to sixteen years. In every one of these cases there was pain, odor, and hemorrhage. There were constitutional symptoms showing an extension into the glands, signs of general cachexia resulting from absorption of the toxines.

Dr. Jerome M. Lynch said he could not agree with Dr. Lloyd that pain was one of the prominent symptoms of carcinoma of the rectum. He had seen two hundred cases with Dr Tuttle and about fifty of his own, 250 altogether about, and rarely was pain a prominent symptom in the operable stage. There was no question regarding the hemorrhage; this he believed to be one of the most important of the symptoms of rectal cancer; it was present in the vast majority of the cases. Patients with carcinoma of the rectum usually gave a history of having some irregularity of the bowels which was followed by either diarrhea or constipation.

Dr. William C. Lusk said that the importance of impressing upon the profession at large the necessity for making a diagnosis of disease conditions affecting the rectum could not be too strongly emphasized. This was borne out by the single fact that physicians so frequently diagnosed cancer of the rectum as hemorrhoids. Dr. Tuttle had mentioned sight and touch as requisite in making the diagnosis. Dr. Lusk said he would urge, in addition, that the man who undertook to make the diagnosis should take the trouble to employ his sight and touch to aid him in coming to a conclusion. The choice of the operation for removal of cancer of the rectum, Dr. Lusk thought would depend largely upon the condition of the patient. A patient with an old heart would not stand a prolonged operation. In a very fat patient it would be desirable to avoid if possible the abdominal route. The younger class of patients who were not too fat were best suited for the radical operation. Dr. Lusk said that he regarded one of the strongest arguments in favor of the abdominal approach to be, that through this route alone the anatomy of the sigmoid flexure could be determined at the very start, consequent upon which the operative procedure could be planned with accuracy and any liberation of the sigmoid and upper rectum could be done in plain view. The attempt to perform high division of the bowel with sigmoid liberation through a posterior approach was attended with many difficulties and much uncertainty. Dr. Lusk said he had made observations of the sigmoids in 25 cadavers, in one of which there was no free sigmoid loop at all, in another the sigmoid took an anomalous course having been bound down by the left leaf of the mesentery of the ileum and having entered the pelvic cavity on the right side, and in a third case the meso-sigmoid was short and so rigid with fat as practically to immobilize the attached bowel. In seven others of the 25 cases the loop of free sigmoid was but from four to seven inches in length, which was of interest in connection with resection of the rectum with high division of the bowel, in which, in order to have enough bowel to reach the anus, the edge of the freed mesosigmoid must be of sufficient length to reach from 5½ to 6 inches below the level of the left common iliac artery. A mesosigmoid attachment up in the iliac fossa could not be liberated through a posterior approach. Another reason for primary approach through the abdominal route was for the ligation of the internal iliae and sacra media arteries, the particular advantage of which was that it greatly diminished the hemorrhage associated with the work done by the lower route. Regarding Dr. Blake's proposition for resection Dr. Lusk said that in Dr. Weir's early cases done by the Maunsell method, bad strictures had resulted, necessitating the use of bougies. He asked Dr. Blake what information he could give on this point.

Specimen of Villous Papilloma.—Dr. James P. Tuttle presented this specimen as illustrative of the point he raised in his paper, the danger of delay. Three years ago a doctor tied off the papilloma at the anus; soon after there appeared a large mass that under ether anæsthesia was reduced. This was two and a half years ago. Villous papilloma was almost always carcinomatous in the early stages; if allowed to go on it, as a rule, would result in carcinoma. This patient was jeopardized for three years because the original operator did not recognize the dangerous condition present in the bowel. Dr. Tuttle said that he was leaning more and more toward the abdominal operation in these cases and he was not so much in favor of the combined operation. There was too much traumatism and too much danger of infection. The growth should be attacked by the abdominal route and an artificial anus should be produced in these cases.

The Dilatation Test for Chronic Appendicitis.—Dr. Walter A. Bastedo read this paper. He described the test by which a latent appendix involvement could generally be recognized. Since the report made in March, 1909, they had applied this test in a great many abdominal cases and had been able, in a number of instances, to establish the diagnosis of appendicitis when all other methods of examination known to them failed completely or left the examiner in a state of reasonable doubt. They had received verbal reports from surgeons in whose experience their test, as checked by findings at operation, had proved reliable, failure being reported in only two per cent. of the cases. To make the test a colon tube was passed ten or twelve inches into the rectum and air injected by means of an atomizer bulb. If, as the colon distended, pain and tenderness to finger-point pressure became apparent at McBurney's point, there was appendicitis. They had compared the test with the Roosing test and found the latter much less certain; but at times, after moderate dilatation by the test just described, the Roosing method of forcing the air back into the cecum might be used with advantage. If most of the air was not allowed to escape before the withdrawal of the tube colicky pains might ensue. The test was not needed in acute cases or in undoubted chronic ones, but it was indicated where there was a suspicion of a chronic or latent appendicitis, or any persistent digestive or abdominal disturbance in which no cause could be found for the trouble. In cases where there were other tender points that gave rise to a doubt as to diagnosis the test often caused all the other tender points to disappear except that at McBurney's point. In persistent cases of hyperchlorhydria or gastrosuccorrhea the test should be performed. Just as in the case of a latent cholelithiasis, so a latent appendicitis might have its chief manifestation in stomach derangement, even so marked at times as to simulate an ulcer. They had met with a number of these cases in which removal of the appendix had caused the gastric symptoms to disappear. A further application of the test might be to distinguish between an inflamed appendix and a right-sided pelvic trouble. Pain and tenderness in a right-sided chronic salpingitis or cystic ovary sometimes resulted from the colon dilatation, but the tenderness was regularly less acute, was low down in the abdomen and extended towards the middle line. In three instances they had been able to diagnose pelvic inflammation without appendix involvement in young women in whom appendicitis was suspected and vaginal examination was impossible. They had employed the test in not a few other gynecological cases and in some had been able to corroborate the findings of a vaginal examination, while in others they had demonstrated appendicitis in addition to the pelvic lesion. Dr. Bastedo cited a number of cases which illustrated the positive findings of the dilatation test. In the use of the test during the past four years they had no case in which the test was positive and the operation findings negative. In two out of all their cases there was a history of an appendix attack and the negative finding of the test was followed within six months by another typical attack of appendicitis; the test was, therefore, presumably at fault as an interval test.

College of Physicians of Philadelphia.

At a stated meeting held May 3 Dr. George G. Ross presented a communication entitled "Perforated Gastric and Duodenal Ulcer," relating a small group of cases illustrating some phases in the symtomatology, diagnosis, and treatment of the disorders named, and analyzing the present status of the subject. Drs. E. H. Goodman and A. Alexander Howell presented a communication entitled "Further Clinical Studies in the Auscultatory Method of Determining Blood-Pressure." This was a second communication on the same subject, and the results of this further study confirmed the conclusions arrived at tentatively in the earlier paper. By this means of investigation much aid is afforded in the differentiation of functional from organic disease of the heart, and also information can be obtained to serve as a guide in the selection of the proper remedial agents. Dr. Joseph R. Tunis presented a communication entitled "Description of a Series of Transverse and Sagittal Sections of Adult Heads." Sawed sections were made of the thoroughly frozen head and the surfaces obtained were carefully polished. The sections were then mounted in an appropriate preserving medium, and they served to exhibit the structure of the cranial contents in an admirable manner. Reproductions of the surfaces were shown in photographs and lantern slides. Dr. T. H. Weisenburg made a demonstration of "Moving-Picture Illustrations of Gait, Station, Tremors, and General Symptoms of Various Forms of Nervous Disease." By means of screen and lantern a series of admirable reproductions were shown of cases of Huntingdon's chorea, tic of the tongue, posterolateral sclerosis, tabes dorsalis, peripheral neuritis, generalized tic, hemiplegia, progressive muscular dystrophy. In this way it is possible to demonstrate certain peculiar motor phenomena and also the methods of obtaining knee-jerk, ankle-clonus, Babinski, and other reflexes.

Pathological Society of Philadelphia.

At the annual conversational meeting held April 27 Dr. Jacques Loeb, of the Rockefeller Institute for Medical Research, delivered an address entitled "Fertilizing Effects of the Extracts of Tissues, Blood, and Sperm." He pointed out that the spermatozoon exhibits two forms of activity with respect to the germ cell. The one is fertilization, the other the preservation of the life of the ovum. The first is dependent upon changes in the cortical portion of the cell, as manifested in a kind of membrane formation, and upon stimulation of oxidation; the second consists in shielding the ovum from the deleterious effects of the oxidation processes that accompany fertilization. Eggs of sea-urchin can be fertilized artificially by exposure to the action of certain fatty acids (resulting in the formation of a membrane) and subsequently to the action of hypertonic solutions of sea water or of certain chemical substances in solution (affording protection against the results of oxidation). While the unfertilized egg may survive for several hours, or days, eggs subjected to membrane formation die in a much shorter time, unless protected through agencies directed toward the prevention of the evil effects of oxidation. Further, of eggs exposed to the action of spermatozoa some die early, while others survive for a longer period. In the former it will be found that only membrane formation takes place by reason of the partial entrance of spermatozoa into the germ cell. In the latter sperm nuclei also gain entrance and afford the necessary protection from the effects of oxidation. It was not possi-

ble to fertilize ova of sea-urchins with dried extracts of sea-urchin spermatozoa, but this could be accomplished with similar extracts prepared from the spermatozoa, as well as with extracts of the tissues and the blood of other animals. The difference is probably due to the fact that in the first instance in the failure of diffusion penetration is necessary, while in the latter cytolytic effects are produced by the extracts of alien tissue.

At a stated meeting held May 25, Dr. J. E. Ashe presented a specimen of "Dissecting Aneurysm of the Aorta." The patient had been a sufferer from senile dementia, 72 years old, and death occurred in consequence of an attack of pneumonia. Autopsy disclosed a dissecting aneurysm of the aorta arising from the descending arch and extending to the iliac bifurcation. At the lower extremity there was an orifice of communication with the lumen of the blood vessel. Just above the diaphragm the formation assumed the proportions of a tangerine orange filled with laminated clot. The aneurysm was in part canalized, and in many places attached to the walls of the blood vessel by bands and strands of connective tissue. No symptoms of the disorder had been noted during life. Dr. Eisenbrey presented for Dr. J. Cooke a specimen of "Adhesion of the Appendix to the Wall of the Ileum, with Opening of the Appendix into the Ileum." Dr. H. B. Allyn and Dr. H. T. Karsner presented a specimen of "Metastatic Carcinoma of the Heart." The patient was a woman from whose abdominal wall a soft mole had been removed, and who later presented symptoms of neoplastic proliferation in the abdomen and chest. Death resulting in the course of a few months sarcomatous deposits were found in most of the abdominal viscera and in the lungs and heart. Dr. Kasner exhibited on behalf of himself and Dr. Ernest Laplace a second specimen of "Metastatic Carcinoma of the Heart." The primary growth had been situated on the femur and was a subperiosteal osteosarcoma. Dr. R. C. Rosenberger reported "A Case of Multiple Parasitism." The patient was a Russian who had passed through an attack of croupous pneumonia and in whose stools there were found the roundworm, the whipworm and ova of balantidium coli and of distoma hepaticum. There had been no symptoms referable to the intestinal tract. Dr. J. H. Musser, Jr., presented a communication entitled "Cysts of the Spleen," reporting the case of a woman from whose left upper abdominal quadrant was removed a large cyst apparently consisting of the remains of an extravasation of blood beneath the capsule of the organ, which itself was somewhat enlarged. Dr. B. A. Thomas and Dr. Margaretta McPhail presented a communication entitled "A Study of Active Immunization with Respect to the Micrococcus Aureus in Animals Completely Pancreatectomized." It was shown that the activity of the immunity processes was greatly lowered in animals from whom the pancreas had been previously removed.

Treatment of Essential Incontinence of Urine in Children.—René Cruchet and Firmin Carles report their results in the treatment of six children with epidural injections of artificial serum into the sacral region. Three cases of nocturnal incontinence were cured and remain so after four and five months. The other cases were favorably affected by the treatment. The child is placed on the left side with one knee drawn up and the injection is made in the sacral region. If more than 10 c.c. of the solution are injected there will be transient changes of sensibility, such as prickling of the skin. No bad effects have been observed from the treatment and the injections are very easy to make.—*Le Progrès Médical.*

Medicolegal Notes.

Due Care in Discovering and Treating Dislocation of Shoulder Joint.—In an action for damages against a physician and surgeon for malpractice in the treatment of an injury to the plaintiff's shoulder joint which she alleged had become dislocated by a fall, the particular allegation was that the defendant failed, upon examination, to discover the dislocation and to apply such remedies as were necessary to restore her injured shoulder to its normal condition, which could have been done by the exercise of ordinary care and skill. In giving judgment for the plaintiff the court said that the mere use of approved tests, or those which have been found to be the best for the discovery of a dislocation or fracture or any other abnormal condition of the human body is not all that is required of a surgeon or physician in the care and treatment of his patient. He must exercise that reasonable skill, care, and proficiency in making the tests and in ascertaining from them the presence of any injury and generally in the treatment of his patient which a member of his profession of ordinary care and prudence should use under the circumstances. He is not bound or confined to any special treatment, but to an ordinarily careful and skillful one. In this case it was for the jury to decide whether the defendant applied the test properly and if he did whether he possessed the requisite knowledge and skill to understand the symptoms which it disclosed, or to apply the proper remedy. A physician entitled to practise his profession, possessing the requisite qualifications, and applying his skill and judgment with due care is not ordinarily liable for damages consequent upon an honest mistake or an error of judgment in making a diagnosis, in prescribing treatment, or in determining upon an operation where there is reasonable doubt as to the nature of the physical conditions involved, or as to what should have been done in accordance with recognized authority and current practice. But the law does not excuse an error of judgment if it occurs by reason of the surgeon's lack of that knowledge which he should possess in order to qualify him for the practice of his profession, or the failure to exercise the requisite skill and diligence.—Long v. Austin, North Carolina Supreme Court, 69 S. E. 500.

Employment of Physician for Injured Employee of Corporation by Its Superintendent—Liability of Company to Physician.—An employee in the mining plant of a corporation was injured by machinery in the plant, and a superintendent of the mine telephoned the plaintiff to come to the injured man and bring another doctor with him. This the plaintiff did, and the superintendent requested the physicians to take charge of the man. In an action by them against the corporation for compensation for their services the evidence showed that the superintendent had no authority to employ physicians at the expense of the company to attend injured employees, and that the custom of the company was not to allow such a libility to be incurred by its agents or superintendents. It was held that the law does not imply an authority in such superintendents to request such services for, and at the expense of, the corporation. The liability of the corporation for the negligence of its agents and servants which proximately injures an employee may extend to medical services to the injured employee, but this liability does not give rise to a contract liability for such services.—Atlantic Refining Co. v. Leffingwell & Berry, Supreme Court of Florida, 54 So., 266.

Construction of Act Incorporating County Medical Societies—Validity of Society's By-Laws.—New York Laws, 1806, c. 138, authorized the incorporation of medical societies in the various counties for the purpose of regulating the practice of physic and surgery. The statue made a diploma from one of these societies a condition of the right to practise. The societies were empowered to pass by-laws as to the admission and expulsion of members. The right to alter or repeal the act was expressly reserved to the Legislature. Various decisions of the courts much limited the right of these societies to refuse to admit to membership and to expel, and the act of 1866, c. 445, was enacted obviously for the purpose of enlarging the powers of the societies as defined by these decisions. By this act any county medical society was authorized to establish such rules and regulations for the government of its members as it might deem fit, and to enforce discipline among its members and obedience to its rules and regulations, with power to otherwise discipline, as might be deemed advisable for the best interest of the society. In passing upon the validity of the latter statute the New York court holds that one who became a member

of a medical society in 1904 could not object that the act of 1866 was an impairment of the contract between the State and the society made by the act of 1866 if the society raised no such objection. The member's contract is to be construed according to the law in force when it was made. Charges were filed against a member of a medical society for misconduct, but he was not served with a copy of them at the time, as he was under suspension on another ground. Subsequently his suspension was remitted and he was restored to good standing. He then tendered his resignation. Three days later a copy of the charges was served upon him. A by-law of the society provided that no resignation should be accepted from a member under charges. The member brought a suit against the society to restrain it from trying him on the charges. It was held that he was under charges when he attempted to resign, within the meaning of the by-law, and thus his suit was premature. The by-law, it was held, was authorized by the act of 1806, even without the authority of the act of 1866.—Ewald v. Medical Society of New York County, New York Appellate Division, 128 N. Y. Supp. 886.

Definition of "Practising Medicine or Surgery."—In an appeal from a conviction for practising medicine without a license it appeared that the appellant practised what he called the "science of chiropractic." The "chiropractor" makes no physical examination of the patient outside of the spinal column. He does not feel the pulse, take the temperature, prescribe any diet, or use any instruments. He simply examines the spinal column, determines whether or not a "subluxation," as he calls it, exists, and, if he finds it "adjusts" it. It was held that this system of practice was within Missouri Acts 1901, p. 207, prohibiting any person from practising medicine or surgery or from attempting to treat the sick without first obtaining a license. The words "attempting to treat the sick" in the act are not limited to attempts to treat by medicine or surgery. Discussing the question what constitutes practising medicine or surgery the court said: "The practice of medicine is not confined to the administration of drugs; nor is surgery limited to the knife. When a physician advises his patient to travel for his health he is practising medicine Broadly speaking, one is practising medicine when he visits his patient, examines him, determines the nature of the disease, and prescribes the remedies he deems appropriate." To say that one does not "treat" but "adjusts," and that he deals not with the "disease" but with the "cause" is merely juggling with words. Changing the name does not change the thing. The practical test to determine whether a practice or treatment is included in the terms "medicine" or "surgery" is often held to be whether a diagnosis is made. A doctor who advises his patient to sleep in the open air is treating him. Such advice, however, is based upon a knowledge of the patient's condition, obtained by diagnosis. The method or extent of the examination is not the controlling feature. When the practitioner makes such an examination of the patient as he regards as sufficient to indicate to him the cause of the trouble and to indicate its proper treatment he has diagnosed the case. Passing upon the validity of the statute the court held that it was valid as an exercise by the Legislature of its police power in the protection of the public health.—State v. Smith, Missouri Supreme Court, 135 S. W. 465.

Definition of "Practising Medicine or Surgery."—In an accident benefit certificate it appeared that the assured died from, in the opinion of the attending physician, acute dilatation of the heart caused by chloroform administered to him preparatory to a surgical operation The certificate stipulated that the insurance company should not be liable for death resulting from surgical operation. It was held that the company was liable; that "surgical treatment" did not include the administration of chloroform under the circumstances of the case. "Surgical treatment" was defined by the court as treating a disease or a patient by means of surgery, which in turn means applying manual operations or instrumental appliances to the affected part for the purpose of curing or relieving the ailment."—Beile v. Travelers' Protective Assn. of America (Missouri), 135 S. W. 497.

Evidence of Medical Examination Made Through Interpreter Admissible.—In an action for injuries caused by an automobile the plaintiff's condition and the history of the case were proved as matters of fact by her testimony. The evidence of a physician who examined her through a companion who acted as interpreter for the physician, in so far as subjective symptoms and the history of the case were concerned, was therefore held not to be objectionable as hearsay but admissible as showing the basis for the physician's diagnosis.—Salminen v. Ross, Circuit Court, Massachusetts, 185 Fed. 997.

Medical Items.

Ocular Troubles in the Course of Albuminuria of Pregnancy.—M. R. Burnier describes three forms of ocular affections occurring in pregnant albuminuria. They are amaurosis, which comes on without any lesion that can be discovered by the ophthalmoscope, and which often comes on suddenly and is transitory; retinitis, which comes from edematous infiltration of the retina, accompanied often by detachment; and neuritis. Amaurosis is the lightest form of trouble, and is generally found in primiparæ, near the end of pregnancy. The diagnosis is easy and the prognosis good. It is caused by a lesion outside the ocular structures, to be found in the cerebrum, but the nature of which is not known. Theory ascribes it to retention of chlorides, with cerebral hypertension, or to mechanical compression due to arterial spasm. Retinitis occurs with or without previous kidney disease. It shows a severe form of poisoning, and the prognosis for the child is bad. Recovery of sight occurs entirely in some cases; about 25 per cent. remain permanently blind; and 40 per cent. recover partially. Neuritis may also occur. The treatment of these conditions when severe demands a resort to the induction of premature labor in order to save the sight.—*Gazette des Hôpitaux.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended July 14, 1911:

Places	Date	Cases	Deaths
CHOLERA.			
Ceylon: Colombo	May 21–27	1	..
Greece: Laurium	July 8	..	Present
India: Calcutta	May 12–20	..	49
Moulmine	May 14–20	..	1
Indo-China: Saigon	May 22–28	8	4
Italy		..	..
Total for continental Italy outside of Naples June 8 to July 6: Cases 374, deaths 116.			
Provinces—Caserta	June 18–21	4	..
Naples	June 11–July 6	216	68
☞ Including cases previously reported.			
Sicily		..	..
Outside Palermo to July 6, 27 cases, 11 deaths.			
Palermo	June 15–July 6	282	75
Monreale	June 18–21	3	1

A CASE OF PELLAGRA WHICH HAD ITS ORIGIN IN PENNSYLVANIA, PROBABLY IN PHILADELPHIA, WITH BRIEF NOTES OF THE DISEASE AS RECENTLY OBSERVED IN NORTHERN ITALY.*

BY M. B. HARTZELL, M.D.,

PHILADELPHIA, PA.

PROFESSOR OF DERMATOLOGY IN THE UNIVERSITY OF PENNSYLVANIA.

A NOTABLE feature of pellagra in the United States is the very wide range of its distribution, cases having been observed in New England, in the South, in the States of the Middle West, and on the Pacific Coast; indeed, although the largest number of cases has been reported from the South, few if any sections of the United States seem to be entirely exempt. So far as I know, however, no case definitely known to have had its origin in Pennsylvania has yet been reported, and for this reason, and because it was observed in a private family and not in an institution, I have thought it worth while to put on record the following case, especially since it presented in a most striking and typical manner the characteristics of the disease.

Grace R., nine years old, born in Philadelphia, where, with the exception of two or three years spent in central Pennsylvania, she had lived all her short life, was referred to the Skin Dispensary of the University Hospital by Dr. Weisenberg because of an unusual eruption which had appeared somewhat suddenly upon the uncovered parts of the skin, viz., the hands, wrists, and face. At her first visit, April 6, 1910, the skin of the forehead, nose, cheeks, backs of the hands and wrists, both flexor and extensor surfaces of the last, were abundantly exfoliating, the skin being a violaceous-brown in color, presenting an appearance much like the dermatitis which not infrequently follows the application of tincture of iodine to delicate skins. A notable feature of the eruption on the hands and wrists was that it ceased abruptly at the beginning of the sleeves, like a pair of gloves. The mucous membrane of the cheeks, pharynx, and tongue was a very bright red and the tongue was remarkably smooth. The child was much emaciated and showed marked hebetude, sitting silent and motionless, with an air of extreme dejection, scarcely answering when spoken to. In addition to the skin affection it was stated that she had suffered much during the past two months from a moderately severe diarrhea, which no treatment controlled.

*Read before the Philadelphia County Medical Society, February 8, 1911.

The history as obtained from the aunt with whom the child lived and who had brought her to the dispensary, was that in August, 1909, the patient began to lose flesh, she became dull and listless, "sitting all day long without moving, always crying"; she continued to lose weight, and eight weeks before her first visit to the dispensary she began to vomit her food; when the vomiting ceased, after some two weeks intractable diarrhea set in, there being three or four watery stools daily. The cutaneous symptoms made their first appearance ten days previous to her visit to the University Hospital. The face and hands became red "like sunburn" over night, and this erythema was followed several days later by vesicles and blebs, "water-blisters," and these in turn were replaced by the exfoliation which was present when she first came under our observation. The aunt regarded this dermatitis as an ordinary sunburn, the child having been out in the sun for some time the day preceding its appearance.

In order that she might be more carefully studied and treated the child was admitted to the University Hospital a few days after her visit to the dispensary. A careful physical examination made at this time by Dr. Van Valzah, the resident physician, failed to disclose any sign of visceral disease. The urine contained neither albumin, sugar, nor any other abnormal constituent. The blood examination revealed a marked anemia and nothing more; the blood-count showing 2,100,000 red cells, 7,300 leucocytes, and 20 per cent. hemoglobin. The differential count gave 35 per cent. polynuclears, 55 per cent. lymphocytes, 6 per cent. mononuclears, 3 per cent. transitionals, and 1 per cent. eosinophiles; a second count made some days later gave practically the same results. An ophthalmoscopic examination showed no changes in the fundus oculi. During the first three weeks of her stay in the hospital there was fever of an exceedingly irregular type: two or three days of normal temperature would be followed by a rise to 101-2° for a day or two, after which the temperature would again become normal. In order to determine the presence or absence of a possible latent tuberculosis a von Pirquet inoculation was made, but the result was entirely negative. Immediately upon her admission to the hospital the patient was put upon a carefully regulated diet, liquid for the most part, and was given moderate doses of quinine and small doses of opium and bismuth for the diarrhea. Under this treatment she soon began to improve; one of the earliest signs of this improvement being a returning interest in the things going on about her, in the visits of her aunt, and in the toys brought her. The diarrhea was much less, there being only one or two loose movements a day, and the skin of the hands and face had about ceased desquamating, although it was still noticeably browner than normal.

As her strength returned she began to spend several hours every day in the sun parlor adjoining the ward, and it was then noticed that, although not directly exposed to the sun's rays, the hands began to show again a slight but noticeable brownish-red erythema. On May 16, when she was discharged from the hospital, she was gaining slowly in weight, the diarrhea had practically ceased, and her mental condition seemed normal; there was still, however, a slight but easily recognized pigmentation of the skin of the hands and wrists. During the next month she made visits every four or five days to the Skin Dispensary, and after a week or two it became quite evident that she was losing ground; her appetite again became poor, she again began to lose weight, and as in the earliest stages of her illness she became dull and listless. In the latter part of June, yielding to the importunity of the aunt, she was permitted to visit friends in central Pennsylvania and nothing was heard of the further progress of the case until in the autumn it was learned that she gradually grew worse after going to the country and finally died October 12; as to the immediate cause of death nothing could be learned.

The clinical symptoms of the case were of so typical a kind that there seems to be but little room for doubt as to the correctness of the diagnosis; the peculiar brown-red dermatitis occurring upon

those parts of the skin exposed to the light, the gastrointestinal symptoms with the bright-red, smooth tongue, and the mental condition were all quite characteristic of pellagra. Of course one of the most interesting as well as important questions connected with the disease is its origin; and it is of much interest to note that it seems to be definitely established that this patient had never eaten corn. The aunt, who seemed a fairly intelligent person, was quite positive in her statements that the family never used cornmeal as an article of food. Of course, I am quite well aware how difficult it oftentimes is to obtain accurate histories as to patients' habits of life, but I think we may accept it as pretty well established that spoiled corn was not an etiological factor in this case.

During the past summer I spent some part of my vacation in northern Italy, in Milan, where, until a comparatively recent period pellagra was extremely prevalent, perhaps more prevalent than anywhere else in the world; indeed, as is well known, one of the names for the malady is Lombardy leprosy. In 1880 there were no less than 10,000 cases of pellagra in the province of Milan alone, chiefly in the rural population, where there were 32.20 cases in every thousand. Through the very great kindness of Dr. Tancredi Pizzini, assistant to Prof. Bertarelli, I had the opportunity to see some twenty-one cases of pellagra. In the Ospedale Maggiore of Milan we found fourteen patients, all men, most of them over fifty years old, in whom a diagnosis of pellagra had been made, but it is only proper to say that this diagnosis was regarded as somewhat doubtful in some of them; they had been sent in from the country as suspects and were being kept under observation until a definite diagnosis could be made. About one-half of them presented a brownish-red erythema of the backs of the hands, ankles, and tops of the feet, accompanied by more or less scaling, while a considerable proportion of the remainder showed only a moderate pigmentation without desquamation. We were told that fully 80 per cent. of these patients had more or less marked gastrointestinal symptoms of some kind, usually diarrhea, but, as a rule, their general health seemed to be fairly good. The majority of them seemed to be rather dull mentally, but whether this was the mental slowness of the overworked and underfed peasant or evidence of disease I was unable to determine, partly because of lack of time to go into details, but chiefly because of my ignorance of the Italian language. These cases represented the milder forms of the disease, the only forms of the malady seen in the general hospital as a rule since the severe and more marked cases are taken care of elsewhere, in special hospitals for the care of pellagrins and in asylums for the insane. Through the kind offices of Dr. Pizzini I obtained permission from the municipal authorities of Milan to visit the pellagrosarium situated at Inzago, about ten miles from Milan, where the cases of pellagra in the province of Milan are taken care of. This is under the care of Dr. Fritz, to whom I am much indebted for valuable and interesting information concerning the cases seen in the small hospital in the town of Inzago, and in the special hospital or pellagrosarium. In the small general hospital in Inzago we found five cases, four women and one man. One of these women presented the usual cutaneous symptoms of pellagra—an erythematosquamous condition of the backs of the hands—and diarrhea; two suffered from a pronounced pellagrous melancholia and had also had an erythema of the hands in the spring, which had disappeared after a little while; the fourth case, one of long duration, suffered from paresis accompanied by marked wasting of the interosseous muscles of the hands. The man observed in this hospital presented nothing but a moderate erythema of the hands and legs accompanied by scaling. The very small number of cases found in the pellagrosarium emphasized in a very striking way the great diminution of the disease in Italy during the last quarter of a century; we saw but two cases here, both young men about twenty years old. This small number of cases did not represent, however, the entire number being taken care of here since there were a number of ambulant cases at work in the fields whom we did not see, as they could not have been brought in without great delay. Both of the young men whom we had the opportunity to examine exhibited a marked, bright-red erythema of the hands, neck, and upper chest, one of them telling with expressive gestures how greatly his hands had been swollen a few months previously: one of them had diarrhea, the other had not. During our examination of the patients in the hospital and pellagrosarium Dr. Fritz called attention to a symptom of which I do not remember to have seen any

mention, viz., a marked loss of sensibility in the pharynx, and he was able to demonstrate its presence in four or five cases. He regarded this as a very common symptom, more or less characteristic of pellagra. In addition to the two well-marked cases referred to, the pellagrosarium contained some thirty boys from eight to twelve years of age, the children of pellagrous parents, who were being kept under observation. I learned that, while it is not believed that pellagra may be inherited, it is thought that the children of pellagrous parents show a greater disposition to it than the children of non-pellagrous parents. None of these children, who had been under observation for six months, had as yet shown any definite signs of pellagra, although one or two of them had gastrointestinal symptoms of a somewhat suspicious character.

It was quite evident that those in authority still regard the eating of improperly cured maize as a potent factor, if not the principal one, in the cause of the malady, for I noticed with interest upon the walls of the schoolroom where the children are taught while in the pellagrosarium two pictures, almost lifesize, one representing a robust laborer with a rake over his shoulder, apparently in florid health, underneath which was the legend, "This man eats good maize," while the other was the picture of a greatly emaciated man with a face lined by suffering, and underneath this one was the inscription, "This man eats spoiled maize and has pellagra."

The observations made in these twenty-one cases, hurried and necessarily imperfect as they were, impressed me much with the difficulties which might surround the diagnosis and the ease with which mistakes might be made by those with limited experience in mild and poorly developed cases. I was more than ever convinced of the danger of attributing too much importance to any one symptom, especially to pigmentation of uncovered parts of the skin when unaccompanied by signs of mental disease or some one of the gastrointestinal symptoms, usually diarrhea, which occur in at least four-fifths of all cases.

ELEPHANTIASIS NON-PARASITICA.*

By W. GILMAN THOMPSON, M. D.,

NEW YORK.

The following cases of elephantiasis nostras are of interest on account of their obscure origin, long duration, and extensive development, as well as on account of the comparative rarity of the disease in this country:

Case I.—The patient was a woman, aged twenty-six years, who was for two years under my observation in Bellevue Hospital, having had marked enlargement of the left leg for two and one-half years previously. When first seen the patient's general health was good and the physical examination, apart from the elephantiasis, was normal. Frequent blood examinations made both by day and night revealed no filaria. A typical blood count gave the following proportions: Red cells, 4,376,000; leukocytes, 16,000; polynuclear cells, 56 per cent.; large mononuclears, 13 per cent.; transitionals, 14 per cent.; lymphocytes, 15 per cent.; eosinophiles, 2 per cent.

When first examined, the entire left lower limb was about one-third greater in circumference than the right. The skin was edematous, rough, harsh, hairless, and here and there raised into irregular folds. While in hospital many attacks of acute lymphangitis occurred, consisting of moderate fever (100° to 101° F.), pains and burning sensations in the leg, increase in swelling, the formation of blebs and the discharge of considerable limpid opaque alkaline serum, containing many leucocytes. Such attacks lasted from a few days to several weeks. The hypertrophy of the skin finally extended over the pubes, the left lower quadrant of the abdomen and the vulva. Nothing in the early history of the patient threw any light upon the original cause of the disease. She had always lived in this country. In early life she had had malarial fever, and during the final six months in hospital she acquired pulmonary tuberculosis, which advanced very rapidly and caused her death.

Case II.—A laboring man, aged forty-three years, who for eight years had elephantiasis of the left leg. He could assign no cause for the onset of the disease; he had always lived in the United States, and he entered Bellevue Hospital for some minor ailment, not connected with the local disease. The left lower limb was enlarged to considerably more than double the size of the right one, and the skin was very tough and leathery, hairless, and from the knee to the dorsum of the foot it was coarsely corrugated, showing numerous blebs and some small patches of pigmentation. Urine and blood examinations were normal. The patient was seen before the discovery of the *x*-rays, but there was no evidence of periosteal involvement. No pain was complained of, and the man could walk in a clumsy manner. His general health was unimpaired. The hyperplasia of the skin extended to that of the penis and scrotum, and for some distance above the left thigh enlarged lymphatic vessels could be made out. From time to time there was considerable lymphorrhea, especially from the leg below the knee.

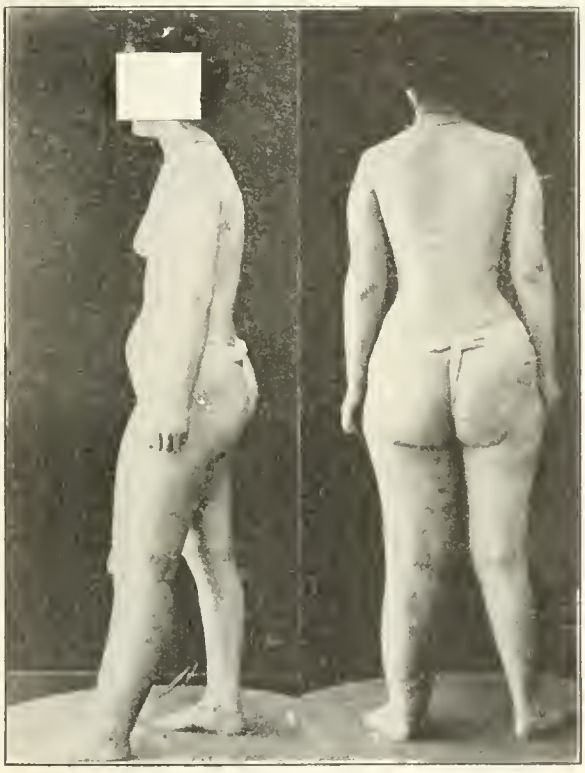

Fig. 1.—Case I, showing elephantiasis of the left leg.

Case III.—A man, aged thirty-three years, who

*Read at the meeting of the Association of American Physicians, held in Atlantic City, May 9.

had always lived in New York. His employment was that of a bookkeeper. No definite etiology of any kind was discoverable in explanation of the swelling of the right leg of which he complained,

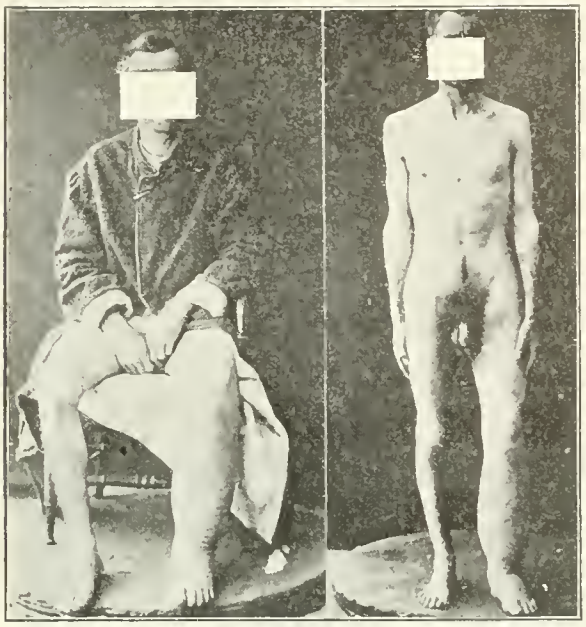

Fig. 2.—Case II, showing elephantiasis of the left leg.

which began in childhood and had lasted continuously for twenty-three years. In connection with its appearance he had repeated attacks of some sort of intermittent fever, lasting sometimes for a fortnight. In each successive attack the leg would become inflamed and more and more swollen. About eighteen

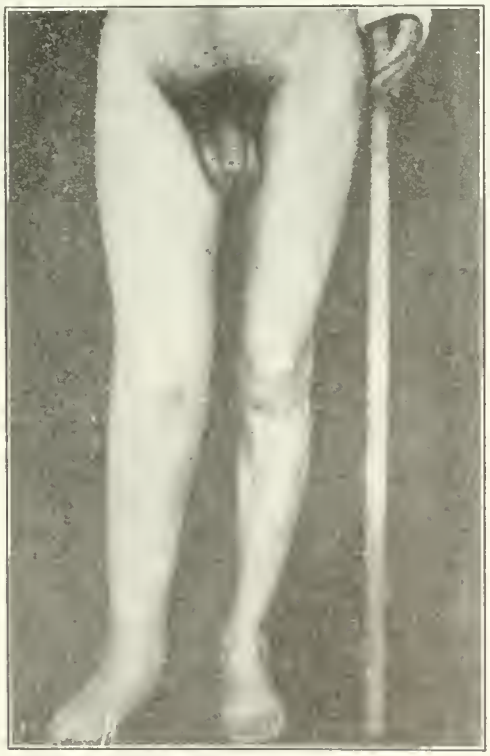

Fig. 3.—Case III, showing elephantiasis of the right leg.

months before he was admitted to Bellevue Hospital he had another attack of acute lymphangitis, with chills, fever (104° F.), and much pain in the leg, which became so swollen that for a time he was unable to walk. The general physical examination of the patient revealed nothing abnormal. Blood examinations were repeatedly made both by day and night, but no evidence of malaria or filariasis was

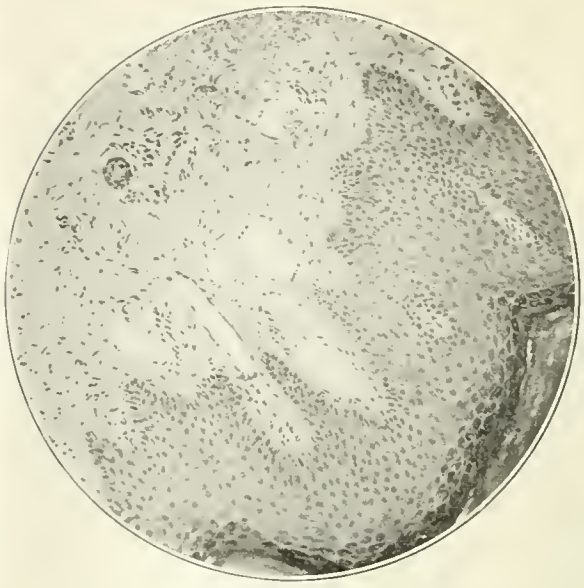

Fig. 4.—Case III, section of skin of foot. (Ewing.)

found. There was slight secondary anemia, and the differential count was normal, excepting a rather high eosinophile ratio—5 per cent. The urine was normal. The entire left lower limb was greatly enlarged, the skin was harsh, leathery, and relatively hairless. Over the ankle and foot, it presented rough folds. The skin of the penis and scrotum became markedly hypertrophic and hairless a year before the patient was first seen. A piece of skin was excised from one of the toes and examined by Prof. James Ewing, whose report on the microscopic findings follows:

"The Malpighian layer is rather thick but practically normal in structure. There is a somewhat excessive layer of cuticle. The derma shows a diffuse

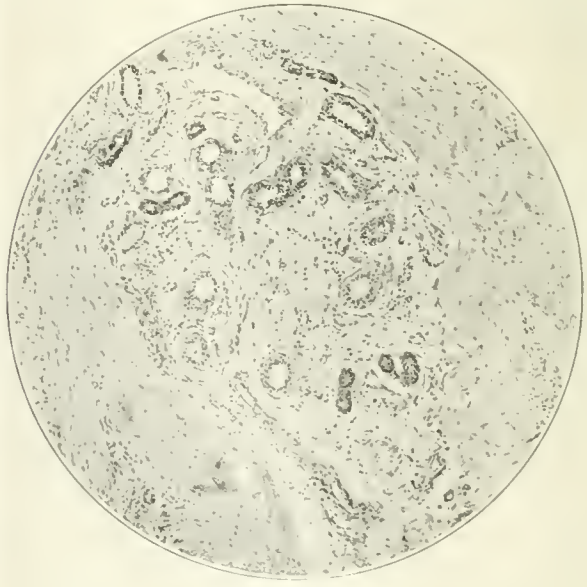

Fig. 5.—Case III, section of skin of foot. (Ewing.)

increase in white fibrous tissue which is further evidenced by extensive chronic edema. There is moderate increase in the small bloodvessels of the derma, and all of these are sheathed by edematous

tissue, containing many lymphocytes. The lymph spaces accompanying the bloodvessels are uniformly rather widely dilated and empty. Many venules are widely dilated and walled by fibrous or fibromuscular tissue. The hair follicles are scanty and the connective tissue is much sclerosed with atrophy of the follicles. The sweat glands show a marked grade of hypertrophy and hyperplasia. Many of the new alveoli are dilated and contain inspissated excretion. The cells lining many of the alveoli are higher than normal. The glands lie in areas of fat tissue showing chronic edema and some mucous degeneration. In these areas there are some new capillaries and round cells. All of these changes, except the alterations in the sweat glands, may be referred to the initial chronic venous and lymphatic congestion, leading to chronic productive inflammation. The changes in the sweat glands might be referred to functional overactivity and chronic inflammation. Summary: hyperkeratosis; thickening of Malpighian layer, dilution of lymphatic vessels and blood vessels; hypertrophy of sweat glands; increase of connective tissue; mucinous degeneration of fat tissue; atrophy of hair follicles."

Fig. 6.—Case IV, showing elephantiasis of left hand and arm.

A radiograph showed normal bones in the leg. The wound made by excision of the skin was very slow in healing and discharged considerable lymph. From time to time herpetic vesicles appeared on the penis, and foreskin, and between the toes. There was no acute exacerbation while the patient was under observation.

Case IV.—This patient was brought to me for diagnosis from the Presbyterian Hospital Dispensary by Dr. Howard C. Williams, Chief of the Surgical Staff, to whom I am indebted for permission to include it with the others.

The patient, a married woman, aged thirty-eight years, presented marked enlargement of the entire left hand and arm to the shoulder. The skin was pale, coarse, slightly roughened and leathery to the touch; the edema did not pit upon pressure. There was no pain and no impairment of motion except that naturally arising from clumsiness. Apart from the swelling of the limb, the condition and health of the patient appeared in all respects normal. Although a native of Germany, she had lived for twenty years in the United States and had never been in the tropics. Her habits were good, and there was no evidence of lues. The woman had had one child and one miscarriage. No diseases of childhood were recalled and the only illness was a single attack of "rheumatism," occurring three years prior to examination. There was no history of trauma or infection of the hand in which the disease began as a painless subacute swelling in December, 1909, about a year before the patient was first seen. The swelling progressed for six weeks, extending up the arm to the shoulder, and has since remained stationary despite varied treatments. The average increase in size of the left arm and forearm above the right was 2 cm. A radiograph showed the bones of the arm to be normal. The patient complained only of clumsiness in the arm, with fatigue on using it in housework. I requested Dr. Walter L. Niles to make blood examinations both by day and night. No filaria were found, and the detailed blood count follows: Red cells, 5,200,000; leukocytes, 7,800; polynuclears, 59 per cent.; lymphocytes, 28 per cent.; large mononuclears, 7 per cent.; transitionals, 3 per cent.; eosinophiles, 3 per cent.

The four cases above reported possessed no history of any disease, injury, or condition which might conceivably have given origin to the lymphangitis. Moreover, in the three cases in which definite history was obtained of recurrent acute exacerbations with fever, advance in the swelling of the limbs, etc., there was no discoverable exciting cause for such recurrences. While it is true that the embryonic filaria is not often to be demonstrated in the blood of patients having elephantiasis Arabum (Manson), none of the four patients had ever left the United States, repeated careful search in each one failed to afford any evidence of a parasitic origin of the disease, the urine was never milky, and eosinophilia was absent. The other various causative factors to which elephantiasis so often has been referred were all also lacking in these cases, such as polyneuritis, phlebitis, repeated erysipelas attacks, anemia, cachexia, chronic cellulitis, trophoneurosis, and mechanical obstruction.

Far from being anemic or cachectic, the patients were well and as active as the clumsiness of the limb affected permitted. Vascular supply appeared normal; there was no evidence of vasomotor disturbance or of abnormal nerve irritation. I have had under observation many cases of post typhoidal or other types of chronic thrombophlebitis, in which, for a dozen or more years there has been edema of one or both legs, but I have never seen elephantiasis develop in such cases, which, of course, are very common. In these cases the edema, unlike that of elephantiasis, remains soft, it varies in intensity (depending much upon position), the skin remains practically normal, and shows none of the histologic changes of elephantiasis, and the recurrent inflammatory febrile exacerbations which characterize elephantiasis, are not present. It therefore may be affirmed that chronic serous edema of blood-vascular origin, rarely, if ever, causes the manifold cutaneous changes of elephantiasis. Moreover, Cohnheim long ago showed that obstructive or experimental lymph stasis does not alone produce

edema, if the lymph is normal and the venous return is unimpaired, and Unna denied that lymph stasis may be a cause of lymphangiectasis. If not an antecedent, however, it certainly clinically appears very early in the disease, as pointed out by George C. Shattuck in a careful review of the "Etiology of Elephantiasis" (*Boston Med. and Surg. Jour.*, 1910, No. 19). The earlier writers upon this topic, such as Busey, argued that lymphatic obstruction, lymphangiectasis and edema of lymphatic origin have multiple causes, such as defects (congenital or acquired) in the lymph vessels, small thrombosis, overdistention, with loss of elasticity of their walls, etc. While this may be true, it is a curious fact that the lymphatic hyperplasia of elephantiasis is so rare an occurrence where the factors above mentioned are present. Moreover, if due to any general conditions, it is difficult to explain why the most advanced cases of elephantiasis nostras, as met with in this country, are usually confined to one limb. The filarial elephantiasis, on the contrary, is occasionally bilateral. Even when venous stasis and general bilateral serous edema is present, due to chronic endocarditis, elephantiasis may remain unilateral, as in a remarkably interesting case pictured by T. W. Hastings (*Amer. Jour. Med. Sci.*, September, 1906), in which the right leg from knee to ankle showed enormous elephantiasis and a cuff-like folding of the skin over the ankle, while the left leg presented merely the soft edema of a general anasarca. The skin in this case became one and one-half inches thick, and there was marked lymphorrhea.

It is thus a very puzzling problem, whether a primary lymph stasis or lymph edema gives rise, through irritation, to hyperplasia, or whether an inflammatory process results in formation of thrombi and lymphangiectasis, with subsequent and not primary edema. Many arguments have been advanced in favor of either theory. In many of the cases of elephantiasis nostras the onset has been gradual, and the disease may have lasted so many years that the patient has forgotten, or perhaps altogether overlooked some primary inflammatory process which failed to give rise to much original pain or swelling in the limb, yet which was the foundation of a progressive hyperplasia of slow, but constant development. On the other hand, it appears certain that marked lymphangiectasis may occur without elephantiasis. In any case the assumption, which has often been made, of the existence of some congenital defect in the lymphatic system seems reasonable, especially in view of the well-known types of elephantiasis growths of subcutaneous connective tissue, associated with edema and observed as congenital deformities (elephantiasis lymphangiectodes).

In Case III, the examination of the skin made by Dr. Ewing showed in addition to the usual chronic inflammatory changes decided hypertrophy of the sweat glands—a unique feature.

None of the patients were materially benefited by treatment. Bandaging, rest, inunctions, hydrotherapy and massage were tried from time to time without avail in staying the progress of the disease.

Familial Pernicious Anemia.—Gilbert and Weil report two cases of pernicious anemia occurring in brothers 44 and 45 years old respectively. They believe that these cases represent a type of progressive pernicious anemia of hereditary origin.—*Tribune Médicale.*

A CASE OF PAGET'S DISEASE.*

By KARL M. VOGEL, M.D.,
NEW YORK.
ASSISTANT ATTENDING PHYSICIAN ST. LUKE'S HOSPITAL, ASSISTANT PROFESSOR OF CLINICAL PATHOLOGY, COLUMBIA UNIVERSITY.

In spite of the fact that ostitis deformans or Paget's disease, as it is generally called, is not a remarkably rare condition, at least in its minor grades, the diagnosis is not very often made, and it is only comparatively recently that cases have begun to be reported with any degree of frequency.

Paget in 1877 first isolated this type of deformity from the general hodge-podge of chronic bone diseases, and in the Medico-Chirurgical Transactions for that year outlined a clinical picture to which subsequent observers have made few additions of moment. As he described it, the disease is one beginning in middle life or later, progressing very slowly during many years, and causing no disturbances other than those due to mechanical changes in the diseased bones. Those most often involved are the long bones of the lower extremities,

Fig. 1.—Photograph of patient at the age of 34 years.

the cranium, spine, and clavicles. The bones enlarge and soften and owing to the pressure of the body weight become curved and misshapen, so that finally with the shortening thus produced, as well as through curvature of the spine, the stature steadily decreases. The pain is variable in severity and is most common in the earlier stages of the disease, though it may persist indefinitely.

In a later communication, Paget[1] summed up the most prominent symptoms, as follows:

"It usually affects many bones, most frequently the long bones of the lower extremities, the clavicles, and the vault of the skull. The affected bones become large and heavy, but with such weakening of their structure that those which have to carry weight or to bear much muscular traction become unnaturally curved and misshapen. The disease is very slowly progressive and is felt only in pain, like that of rheumatism or neuralgia, in the affected limbs and in increased heat at the tibiæ. But neither the pain nor the heat are constant, nor do

*Read at a meeting of the Section on Medicine of the New York Academy of Medicine, May 16, 1911.

they continue during the whole progress of the disease; and pain has not been observed in the head even in the cases in which the skull was very thickened. There is not any clear evidence of general disturbance of health. In all the cases traced to the end of life death has ensued through some coincident, not evidently associating, disease, which has been aggravated by the condition of the bones only in so far as they may have diminished the range of breathing and the general muscular activity.

"In all of the cases I have seen the general appearance, postures, and the movements of the patients have been so alike that these alone might often suffice for the diagnosis of the disease. The most characteristic are the loss of height, indicated by the low position of the hands when the arms are hanging down; the low stooping with very round shoulders and the head far forward, and with the chin raised as if to clear the upper edge of the sternum; the chest sunken toward the pelvis, the abdomen pendulous; the curved lower limbs, held apart and usually with one advanced in front of the other, and both with knees slightly bent; the ankles overhung by the legs, and the toes turned out. The enlarged cranium, square looking or bossed, may add distinctiveness to these characters, and they are completed in the slow and awkward gait of the patients and in the shallow costal breathing, compensated by wide movements of the diaphragm and abdominal wall, and in deep breathing by the uplifted shoulders."

In regard to the order of involvement of the bones it may be stated that Packard, Steel, and Kirkbride[2] from an analysis of a very large number of cases found that this was as follows: Skull, tibiæ, femur, spine, pelvis, clavicles, ribs, radii, ulnæ. The fibulæ seem to be but rarely affected, but Maier

Fig. 2.—Photograph of patient at the age of 44 years.

has reported a case in which the disease began in one fibula and in the small bones of the foot.

Paget correctly interpreted the condition as being a chronic inflammatory process, and accordingly suggested that it be known as ostitis deformans. Recklinghausen termed it ostitis fibrosa. The changes in the bone structure may be regarded as the result of two opposing processes, resorption and hyperplasia; that is, a rarefying and a condensing ostitis. Both the spongy and the compact portions of the bone are involved, the destruction of the lamellæ being accompanied by replacement with fatty, gelatinous, or fibrous tissue which frequently

Fig. 3.—Present appearance of the patient.

shows localized areas of softening and liquefaction, so that cyst-like cavities filled with fluid develop. In addition, calcification occurs and irregular deposits of new bone are formed throughout the entire substance of the bone, resulting in an increase in its size and density. The marrow becomes converted into a more or less fibrous or gelatinous mass containing giant cells, fat cells, and leucocytes.

Various authors differ somewhat in their views as to whether the process begins subperiosteally or in the marrow, and as to the precise sequence of events; but the essential features are the combination of softening and curvature of the bone, together with an increase in size and density, so that the picture presented by the individual bones may be very variable, and the processes of halisteresis, absorption, and calcification of newly formed osteoid tissue may be going on simultaneously. The surface of the bone may be smooth or rough; the cortex compact or spongy; the cancellous portion dense or porous; the central canal almost obliterated or widely dilated.

In regard to the etiology little more is known than in Paget's time. General arteriosclerosis is constantly present and it has been suggested that the bone lesions are due to sclerosis of the nutrient vessels of the bone. French observers have considered that the disease is a manifestation of hereditary syphilis or a paraluetic condition, and have reported improvement as the result of mixed treatment. Nerve lesions and gout have also been mentioned as possible etiological factors, but without very satisfactory confirmatory evidence. Joint changes occur but are not very common, although Richard and Ziegler hold that the disease is allied to arthritis deformans. Prince[3], who regarded the disease as a trophic disorder, has laid stress on the possibility of there being changes in the central nervous system, but as yet nothing significant has been dis-

covered. An interesting fact noted by Paget himself as well as by later writers is the comparative frequency with which new growths of various sorts, including osteosarcoma, occur in the subjects of the disease. A possible hereditary predisposition has been alleged, since in a number of instances mem-

Fig. 4.—Present appearance of the patient. Note especially the low position of the ear.

bers of the same family have been victims of the disorder. Bockenheimer[4] holds that a congenital anomaly of bone metabolism is an underlying factor.

The direct prognosis, as far as life in concerned, is good, though a subject of the disease through arteriosclerosis and through local conditions dependent upon the deformity may be more susceptible to the disorders of old age than an individual not so affected.

The treatment is largely symptomatic and consists chiefly in controlling the pain, when present, though some writers have reported encouraging results from the administration of thyroid extract. Attempts at surgical correction of the deformity of the long bones are contraindicated. In one case of Sonnenberg's[5] in which an osteotomy was performed there was no evidence of callus formation thirteen months later.

The question of diagnosis is a more complex one, for while it is not very difficult to recognize the disease when well advanced so that the curvature and enlargement of the bones are apparent, the head is misshapen, the stature shortened, and the patient presents the typical ape-like aspect, in its earlier stages or in mild cases, when, perhaps, only a single bone is involved and the patient complains solely of fleeting pains, it is no doubt often mistaken for sciatica, rheumatism, neuralgia, arteriosclerosis, etc., and many cases are accordingly overlooked. Among the bone diseases that might be confounded with it are osteomalacia, spondylitis deformans, hypertrophic pulmonary osteoarthropathy, and possibly acromegaly, but these all differ in more or less striking particulars from Paget's disease when well developed. One form of disease, however, requires especial mention in this connection, and that is the diffuse enlargement of the skull described by Malpighi in 1697, and to which Virchow gave the name of leontiasis ossea, because, as he said, in looking at representations of such skulls one is reminded of the appearance of the plaster cast of a case of leprous leontiasis. Later authors, however, prefer the designation "diffuse cranial hyperostosis." Most of the writers on bone disease have apparently taken it for granted that this condition and Paget's disease are independent affections, and have given various differential points by the aid of which the two might be distinguished. These relate chiefly to the age at which the disease first appears, and to minor distinctions in regard to the nature of the bony changes, extent of involvement of the fissures and foramina of the skull, the occurrence of nervous disturbances, etc. Recent authors, however, notably Bockenheimer, Prince, and Fitz[6], have suggested that the two conditions are certainly closely allied and probably identical. But the question has remained a somewhat open one because until rather recently information as to the leontiasis skulls was largely derived from more or less ancient museum specimens generally provided only with inadequate

Fig. 5.—Radiograph of the pelvis and femur.

clinical histories so that the possible coexistence of slight changes in other bones could not be altogether excluded. Latterly more definite data have been available, for the microscopic examination of tissue removed at operation on leontiasis patients for the purpose of relieving pressure symp-

toms has revealed changes precisely similar to those found in the long bones in Paget's disease. An important contribution to the matter was made not long ago by Max Koch[7], who presented before the German Pathological Society the skull of a carefully observed patient clinically suffering from leontiasis, which showed on section the usual appearances of Paget's disease; so that it now seems rational to regard leontiasis ossea as a local occurrence of lesions which when more widely distributed produce the picture of Paget's disease.

The history of Koch's case is briefly as follows: The patient was a woman of 65 years, who was observed during a year's stay in the hospital. The symptoms began twenty years previously, when she noticed an increase in the size of the head and at the same time tinnitus, vertigo, headache, and impairment of vision developed. Her hearing became impaired only a few months before her entry

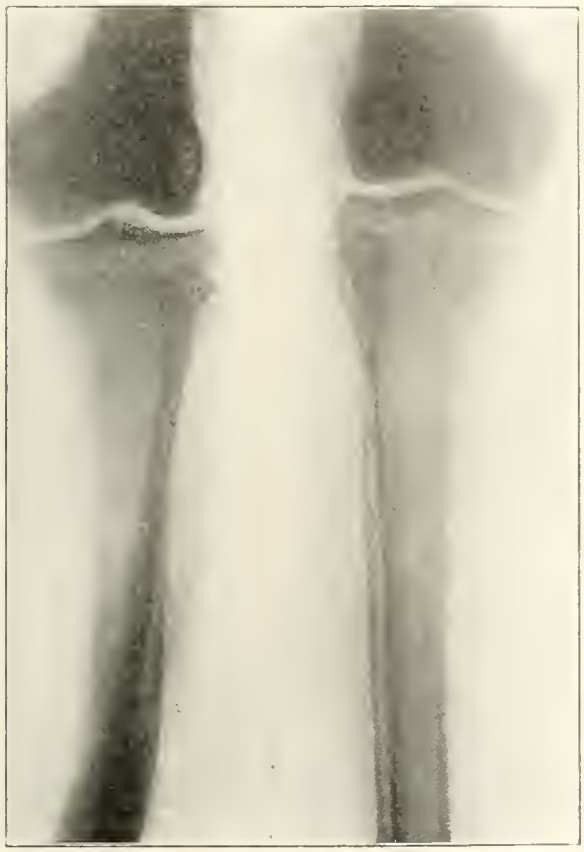

Fig. 6.—Radiograph of the tibiæ.

into the hospital. The circumference of the head was 72 cm., or about 29 inches. There was pronounced enlargement of the temporal arteries, and the ears stood out prominently from the head. Ophthalmoscopic examination was negative, and the visual fields were not restricted. Myopia of —5 D S. There were hyperostoses of both external auditory meatuses and hypertrophy of the inferior turbinates and nasal septum. The hard palate was so much thickened that the laryngoscope could not be used. The lower jaw was not thickened. The Wassermann reaction was negative. During her stay in the hospital she suffered chiefly from headache, pain in the legs, vertigo, and general weakness. Five days before death she suffered from an apoplectiform attack with unconsciousness, but no paralysis. Death appeared to be due to a general loss of strength. At the autopsy it was found that there was a synostosis between the axis and third cervical vertebra. There was a moderate kyphosis in the thoracic region, but no abnormality of the other bones. The blood-vessels were markedly sclerotic. On sawing through the skull it was found that the differences in structure between the external and internal tables and the diploe had disappeared, and the bone was very friable. The thickness of the frontal bone was from 4 to 6 cm., that of the temporal from 3 to 3.5 cm., and of the occiput, 2.5 to 3 cm. There was an abscess cavity in the situation of the frontal sinus on one side, but on the other the sinus had been entirely obliterated. The cut surface was made up of spongy bone with grayish red dense fibrous tissue with here and there areas of gelatinous marrow or cavities filled with fluid. All the foramina and fissures of the base were much narrowed except the foramen ovale. The meninges were normal, but the brain appeared flattened and diminished in size through pressure. The pituitary body was flattened, but in section showed no abnormalities.

Microscopical examination of the bone showed the changes described by Paget as ostitis deformans, and by von Recklinghausen as ostitis fibrosa. Koch accordingly believes that this case definitely proves the identity of leontiasis ossea with Paget's disease.

The history of the case forming the subject of the present report is as follows.

The patient was a woman aged 68, born in England, a seamstress. Admitted to St. Luke's Hospital on December 5, 1910, to the service of Dr. Janeway.

Family history negative, except that one sister is said to have died of cardiac trouble and various members of the family have had "weak hearts." There is no history of bone changes similar to those of the patient, and all members of the family are well formed, active individuals.

Previous history: When about two years old her head was caught between a clothes mangle and a door. She says that her head has always been large and ill-formed, and believes that this is due to this accident. She has no remembrance of the diseases of childhood. At eleven years of age, after a fright, she had "fits" during which she would become unconscious, but she does not remember falling or hurting herself during these attacks. A short time later she awoke one morning and found that her right side was paralyzed. For a time she had to be fed and helped in walking, but the paralysis gradually disappeared and she had no more of the fits after her sixteenth year. About twenty-five years ago she had several abscesses in the left external auditory canal, and at the same time that side of her head became swollen and bumpy. She believes that the present swelling above her ear is due to this cause.

Present illness: Dates back about fifteen years. Previous to this time she had always been a good walker, but she then began to notice a feeling of weakness in her legs which gradually increased until about ten years ago, when she was obliged to give up her work as it took her so long to do anything and she could not think quickly. If she wished to do anything across the room it would take her half an hour in thinking about it and in getting up and crossing the room. She had some dull pains in her legs at this time and also began to grow deaf. During the last five years the pains in her legs have become more severe. Her gait

has become very slow and shuffling and she cannot lift her feet. Two years ago she noticed that the legs were becoming crooked. She has suffered from headache most of her life, and lately her head has felt heavy, so that it drops forward and it is hard for her to lift it. She is afraid to lift her head too high in looking at things for fear she will fall over backward. She believes that she has become two inches shorter during the past five years. She is of a hysterical nature and has always cried easily, but she has found that lately she cannot shed a tear, and has also found that the bridge of her nose has grown too large for her glasses. For four or five years her legs have been more or less swollen and recently her arms also have become edematous. For about a year she has been short of breath and the veins in her neck and on her forehead have become prominent.

The patient is depressed, realizing fully her slow mental processes and her inability to move or act quickly.

Chief complaint: Shortness of breath and swelling of arms and legs.

Physical examination: General condition: patient is a rather poorly nourished woman of small frame, past middle age, showing moderate dyspnea but only slight cyanosis. Her appearance is very striking on account of the marked disproportion between the size of the head and that of the body. The head is very markedly enlarged especially in the upper part; it is rather square in shape, with pronounced bony protuberances above each ear. Circumference about the forehead is 65 cm. or 26 inches. In the temporal region and in the neck are numerous markedly distended pulsating veins. The skin of the face appears rather pale and pasty, with numerous brownish pigmented areas. Eyes: pupils equal and react to light and accommodation. Tongue, clean. Throat normal. Upper teeth artificial; lower in fair condition. Chest poorly developed; slight protuberance of upper part of sternum. Heart: rather diffuse pulsation over the lower precordium. The apex impulse is fairly well marked in the fifth space, four inches to the left of the median line. The right border is one inch from the mid-line; the left border merges with the dullness of the left chest. At the apex there is a loud blowing systolic murmur transmitted to the axilla and heard over the entire lower left chest. The second sounds are not accentuated; the action is rapid and irregular. The pulse is rapid, irregular, of poor force, and moderate tension. The vessel wall is thickened. Lungs: clear anteriorly; posteriorly there is dulness beginning just above the angle of the scapula on both sides and becoming flat on approaching the base. Over this area there is diminished breathing, becoming absent at the base, where numerous subcrepitant râles are heard. The abdomen is somewhat distended. The liver percusses three inches below the free border, where its edge can be felt indistinctly. It is markedly tender and pulsates. Extremities: both legs are markedly edematous and show moderate curving of the tibiæ.

The patient's height at present is 4 feet 10⅞ inches, whereas she says that previously it was 5 feet 1½ inches, a shortening of a little over 2½ inches. She is very deaf, but examination of the ears shows no occlusion or deformity of the external meatus. The drums show several patches of fibrous thickening.

In conclusion it may be said that a survey of the literature seems to support the contention that the separation of diffuse cranial hyperostosis as an independent disease is not justified and that it is to be regarded as a manifestation of the same process which is responsible for the symptom complex of Paget's disease. Further evidence in favor of this view is furnished by a case recently reported by Bartlett,[9] in which, as in that described by Koch, during life there was no sign of the involvement of any bones except those of the skull. At the autopsy, however, examination of the femur showed beginning foci of disease.

SCROFULA.

By SAMUEL EHRENREICH, M.D.,
NEW YORK.
ASSISTANT HOUSE PHYSICIAN MONTEFIORE HOME AND HOSPITAL.

Scrofula, or scrophula, is a condition characterized by a chronic enlargement of the lymphatic glands, particularly those in the neck, under the chin, and behind the ears, and by a general cachectic state usually due to tuberculous infection. This condition is so called because of the marked resemblance of scrofulous patients to the pig, the peculiar shape of the neck with thickening of the nose and upper lip giving this appearance (*Scrofa*—sow).

About fifty years ago any chronic state of ill-health under the age of fourteen was accredited to scrofula. As Henle well remarked, "Scrofula is the receptacle into which one vaguely casts all the ailments which affect children, and of which we do not know the cause." Before the discovery of the tubercle bacillus by Koch in 1882, the relation of scrofula to tuberculosis of the lymphatic glands was obviously a very vague and indefinite one. Later, tubercle formation was found in many but not in all cases of scrofula, and the distinction was made by the fact that those glands which showed distinct tubercles were tuberculous and those that presented only the immature structure, scrofulous. Rindfleisch considered scrofula as the starting point of the tubercle-producing process. He believed that the tubercle is usually derived by a process of infection from some near or distant seat of scrofulous disease. As far as we know about the causative factor of scrofula to-day, we can only say that the tubercle bacillus is usually responsible for the affection, but that this is always the case has not been proved; furthermore, that scrofula is due to a diminution in virulence (Arloing, Lingard), or in quantity of bacilli (Nocard), or that in this state vaccination with tubercle takes place has also not been shown in every case. Scrofula formerly included many lesions, *e.g.* lupus, white swelling, deep affections of the skin, mucous membranes, bones, and joints, and others, but with all these removed there still remains a special morbid temperament which is fairly characteristic, as the case I report

will show, and to which alone the term scrofula should be applied.

Etiology: Age. Although met with at all ages, scrofula is essentially a disease of early life, especially between the ages of five and fourteen. Heredity. Phthisis in parents is a common predisposing factor of scrofula in children; a fair number of cases is found in patients whose parents were simply in a deteriorated state of health. There are undoubted cases where syphilis in the parents has produced scrofula in the offspring. Marriage of near kin, advanced age of parents, disproportion in their respective ages and especially advanced years in father, are said to be responsible for the predisposition. Sex. The disease is about equally as common in both sexes. Locality and climate. Cold and damp climates are predisposing factors; the disease is also more commonly seen in temperate zones than in extreme north or in the tropics. Unhygienic surroundings, overcrowding, absence of sunlight, insufficient or unsuitable food, cold and damp, all favor the development of the affection. Richard Carmichael considered digestive disorders as an important exciting cause in the development of scrofula. Measles, whooping-cough, typhoid, and other disease also favor its onset. It is measles especially which hastens the evolution of scrofula, and it is as a sequel of this disease that we note the persistence of a scrofulous ophthalmia, otitis, coryza, or eczema. While in many cases the portal of entry of the tubercle bacillus, or other exciting agent, is not evident, the importance of the tonsils as an infection atrium must not be forgotten, and this has of late been urged. In concluding the etiology I wish to state that scrofula surely is on the decrease; cases of true scrofula are comparatively rare, and are occasionally mistaken for some other disease.

Pathology: The earliest manifestations of the disease consist in an enlargement of the lymphatic glands, usually the cervical which cannot be distinguished at first, either clinically or pathologically, from a simple chronic hyperplasia. The gland may enlarge to a varying size and on section looks pinkish in color and is of a firm consistence. All that is noticed on microscopical examination is a great increase in the lymphatic corpuscles, in addition to some overgrowth and thickening of the fibrous capsule and trabeculæ. In most of the glands typical tubercle development soon appears, although in some cases this is only evident to a slight extent or not at all. The tubercle bacilli, while sometimes absent, are often present and virulent. Caseation, although usually occurring in tuberculous inflammation of the glands, may or may not appear in scrofula, for the progress is very slow and usually of a very mild character. If caseation does supervene, the nodes may soften and break down, and by the establishment of purulent and necrotic inflammation about them abscesses may form, which may open externally; these abscesses may heal but usually the healing process is very difficult and slow. Instead of softening, the cheesy material in the nodes may become dry and hard and may undergo calcification. A certain amount of periadenitis is almost always present, though not to any great extent in the early stages; if suppuration occurs the glands become adherent not only to the neighboring glands, but also to the surrounding structures. In many of the more chronic cases the fibro-cicatricial tissue may be so extensive as to fix the mass firmly to the deeper parts. The scrofulous affections of the mucous membranes are of a catarrhal nature, furnishing mostly a profuse, comparatively thick secretion, which readily dries and shows great capacity for irritating the skin at all points of contact, especially at the organs of special sense, easily causing erythema and eczema.

Symptomatology: Scrofula is a term employed to express a general condition and not to describe the actual lesions in the lymph glands; in this respect it differs from simple tuberculous adenitis. In addition to the gland involvement there are signs, subjective and objective, showing that the entire body is more or less affected, the changes probably being due to the toxins generated by the tubercle bacilli absorbed in some way into the body. Soltman suggests their absorption from the placental blood in intrauterine life; but this can hardly hold good in the acquired cases of scrofula. Formerly, when the term scrofula was applied to a varying number of different conditions, the physiognomy of a scrofulous individual was naturally said to have no characteristic appearance. The patients were divided into two types: the sanguine, in which the individual was tall, graceful, with a fine, clear skin, fair complexion, oval face, small lower jaw, delicate and regular features, thin lips, and mentally very bright and intelligent; the phlegmatic, in which he was short and burly, coarse limbs, large hands and feet, broad face, large lower jaw, prominent malar bones, dull, heavy aspect, thick, coarse skin; persons of this class appear flabby and heavy-looking; they are apathetic, have little muscular power, and are soon tired. A typical case of scrofula (as in the case I report) presents a general appearance more or less resembling that of a pig; features are coarse, patient looks weak and pale, lips are thick (especially so the upper); eyes are bleared, nostrils excoriated, glands of the neck enlarged, so that facies have a fairly characteristic appearance (see photograph). Multiple scrofulous manifestations in the skin, mucuous membranes, and special sense organs may also be present. Among cutaneous lesions we have to note eczema, localized by preference around the natural orifices of the head, nose, the lips, ears, and eyes. The soft tissues have very little resisting power and may suffer from the effects of the most insignificant traumatism. When the rhinitis, which is usually present, is accompanied by a persistent discharge, the upper lip, and occasionally the lower, which is thus constantly irritated, becomes enlarged and the seat of a diffuse lymphoma, the large lip of the scrofulous. Hypertrophy of the tonsils, chronic pharyngitis, hypertrophy of the lymph follicles and adenoid vegetations are commonly observed in these cases. Scrofulous localizations are especially frequent in the eyes, and the scrofulous ophthalmia may be primary or provoked by some acute disease, such as measles. Its usual form is a ciliary blepharitis, a sort of eczema of the free border of the eyelids, resulting finally in a falling of the lashes. A conjunctivitis often follows and a slight discharge thus causes agglutination of the lids.

The character of involvement of the lymphatic glands differs in different cases. The glands in the neck, behind the ears, under the chin, and in the axilla are most commonly affected, although the inguinals, bronchial and mesenteric, may become similarly involved. A simple hyperplastic process causes usually a painless, gradually increasing swelling, which is capable of simple resolution. The more voluminous, harder tumefaction, in which the glands coalesce into larger bunches, corresponds to cheesy degeneration; in this stage inflammation

of the surrounding structures may follow, causing the glands to become painful, the skin over them losing its mobility to a great extent, becoming reddened; abscesses may form, which may break on the surface. If, on the contrary, the breaking results from the softening of cheesy material of the gland, a scrofulous ulcer is formed, which is characterized by a foul, lardaceous bottom, and livid, mostly flaccid, more rarely infiltrated, margin. It is a striking fact that the general health may be very good even when these multiple glandular tumors exist for a long time. In other cases no ulcer forms; the glands diminish somewhat in size, yet remain for a long time stationary in the form of bulbous tumors of still considerable volume. In such cases we may often see a gradual extension of the disease to other glands.

Diagnosis: If scrofula be limited to those cases of which I have given a typical description above and shall describe below, the diagnosis will not be difficult; the typical facies in combination with the enlarged cervical and other glands makes a fairly characteristic picture, and the diagnosis a comparatively simple one; when a case is once seen a mistake will never be made.

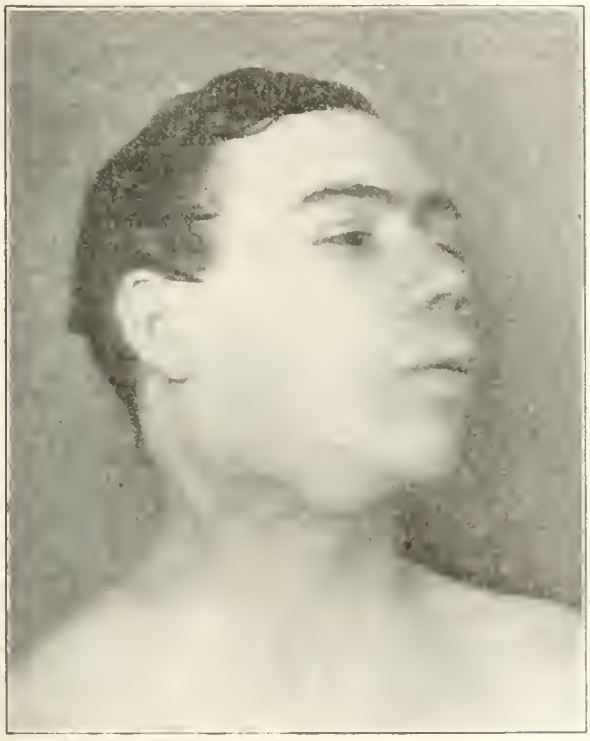
The prognosis varies according to the extent and seat of the lesions; a weak and delicate constitution and a bad hereditary history make the prognosis worse. The scrofulous lesions are very slow in their development, are obstinate, and prone to relapse, the latter occurring four times in my case. The disease becomes extinct oftener at the time of sexual development than at any other period; individuals who have suffered during childhood from severe and obstinate forms of scrofulosis attain the best of health about this time and show no weakness resulting from their previous disorders. In other cases, however, phthisis may develop, this being the most frequent cause of death in scrofulous patients.

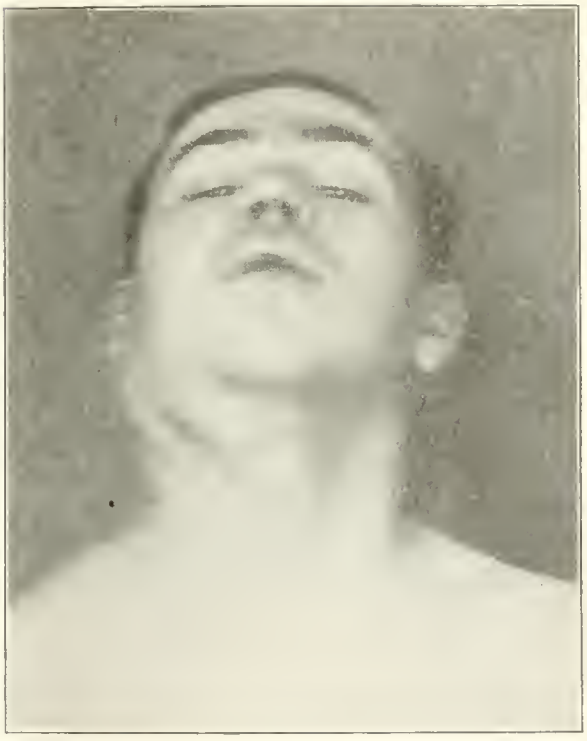
Treatment: This is mainly of a prophylactic nature; so far as scrofulosis is caused by hereditary predisposition, we are almost powerless as to prophylactic measures. A prophylaxis beginning *ab ovo* would be very desirable by preventing all marriages of individuals from whom a scrofulous progeny might be expected with probability; such a proposition is, however, impossible of execution. There are many measures of universal application which, if thoroughly carried out, aid a great deal in preventing the onset of scrofula. Of these I shall only mention the most essential. Children of tuberculous or previously scrofulous mothers must not be allowed to be nursed at the maternal breast. The best substitute is a healthy, strong wet-nurse; when this cannot be had, artificial feeding must be resorted to. Another harmful factor is the feeding of children in the first years of life on the diet of adults; this favors the development of scrofulosis. Even in later years all articles of food which irritate the alimentary canal, and contain too small a quantity of nutritive materials in proportion to their bulk and weight, ought to be avoided, *e.g.* potatoes. The proper regulation of the number and quantity of meals is of no less importance than the selection of their quality. Of even greater importance is the inhalation of pure air. Frequent exercise in the open air, and well ventilated sitting and bedrooms are absolutely necessary; also the proper ventilation of schoolrooms. As to the hygienic treatment of children in other respects, special attention should be drawn to proper muscular training and culture of the skin. Proper instruction in gymnastics, which is compulsory in our public schools, is certainly a great factor in reducing the number of scrofula cases. For general treatment almost every tonic in the pharmacopeia has been recommended, especially so cod liver oil, iron, and strychnin. Iodin has been used internally (as the syrup of the iodid of iron or potassium iodid) and externally, applied locally to the enlarged glands. A very good form of internal medication is the combination of Fowler's solution and potassium iodid, starting with small doses and increasing the dosage gradually. When a large number of glands remain enlarged, or the glands increase in size, or even when one gland continues to grow or by its size promises to do harm, excision should be practised. When there is a tendency to suppuration the gland should be opened as soon as possible to prevent the formation of the horribly deforming cicatrices; if suppuration continues, the gland should be curetted. Of course, general treatment is absolutely necessary, *e.g.* sufficient and wholesome food, fresh air, regular habits, no excesses, etc.

The case I wish to report is a very typical one, but an interesting feature is the fact that the disease began when the patient was 12 years of age. He first came under my observation January 6, 1911, when the following data were obtained: B. B., 18 years of age, was born in Austria. His family history is of absolutely no importance, with the exception that his father is suffering from rheumatic fever and chronic endocarditis. The patient is the oldest of six children; he had measles at 2 and whooping-cough at 6; otherwise he enjoyed good health until the onset of the present trouble. He has always been very moderate in his habits, and positively denies any sexual indulgence. He was a newsdealer, has never worked very hard, but has always lived under very poor hygienic conditions and surroundings. His present illness dates back six years, when the patient first noticed a small papule behind and below the right ear; he consulted a physician, who treated the condition with a black ointment, probably ichthyol; in spite of this the pimple gradually increased in size, the enlargement extending in a downward direction, and at the same time other similar nodules appeared on the right side of the neck. He had no pain, redness, local heat, nor was there ever any tenderness or fever. A year after the onset the mass was about the size of the patient's fist, and the growth commenced to interfere with the normal respiratory functions, especially during the night, causing insomnia. The patient asserts that at this time there were about five or six masses united in one clump, and a number of smaller nodules surrounding this; no softening or abscess formation ever occurred, but owing to the pressure symptoms the patient was operated upon at this time and all diseased tissue removed; wound healed nicely in a month, and the patient was free from any symptoms for four months, after which time a recurrence was noticed on the right side of the neck and a simultaneous enlargement of the scapular group of lymphatic glands, and within seven months there were nodes under the chin, in the neck, behind the ear, and over the shoulder, the entire mass being of greater size than before operation; there was neither softening of the affected area, nor pain, etc. He was operated upon again, improved for one year, and has undergone two operations since, the last one in April, 1909. Since then the glands again increased in size, for the first six months only, for during the last year their size has remained about stationary; six months

ago the left side of the neck was involved, as was also the right axilla. During the past year the patient has been suffering from a more or less constant discharge from the nose, which has been very irritating to the upper lip, causing a hypertrophy of the latter. At the same time the patient noticed a purulent discharge from the eyes, which showed a reddening, especially at the outer canthus; the eyelids agglutinated every morning. He has had no interference with hearing. About four months ago the patient had a general rash, of a reddish macular character, which disappeared after three weeks' treatment with sulphur ointment. The patient has coughed slightly for many years, has never had any fever nor respiratory symptoms, but has lost weight and strength since the onset of illness. There were no gastrointestinal or urinary disturbances or edema at any time.

Status Præsens: As one obtains a first glance of the patient one cannot help but be reminded of a sow; the enlarged cervical glands, in combination





with the great size of the upper lip and nose, strikingly create this resemblance. The patient is anemic, of poor general nutrition, and of medium height and build. There are no skeletal deformities. Station and gait are normal. The head is brachycephalic in type and constantly kept bent toward the left side at an angle of 65°. The right side of the face is greatly enlarged and misshapen owing to the enlarged glands; the upper lip is about three times the size of the lower and protrudes over the latter; the nose is short and flattened, with ala nasi dilated and thickened, and having a slight excoriation, eczematous in type, due to the irritating nasal discharge; the skin over the nose is very glossy, but there is no tenderness. The eyes are comparatively small in size, owing to thickening and consequent ptosis of both upper lids, more so the left. There is an eczematous affection of the free border of the lids, and most of the eyelashes are gone. At the outer canthus of both eyes a redness and fissured skin are evident; these are also more marked on the left side. Pupils are regular, react normally to light and accommodation; there are no ocular palsies or nystagmus present. The entire skin is normal with the exception of the presence of a few scars in the neck, due to previous operations. The mouth cannot be opened more than one inch, and slightly deviates toward the left side; the tonsils are moderately enlarged; teeth and gums are in fair condition; the tongue is flat, broad, and coated. Lungs: There is some impairment of the percussion note, with the presence of a few subcrepitant râles (after cough) over the left apex anteriorly and posteriorly. Otherwise findings are normal. The heart is apparently negative, as is true of the abdomen and extremities. Glands: The postauricular, cervical, submaxillary, and scapular glands are enlarged on the left side, forming a continuous chain, which is quite firm in consistence, not painful and not tender; there are no evidences of softening anywhere; the size of the entire mass is 4 inches by 4 inches; the cervical glands on the left side enlarged only to the size of 1 inch by 1 inch. The axillary nodes on the right side are also affected; the epitrochlears are palpable on both sides. There was no redness or other signs of inflammation present anywhere, and no fever. The sputum examinations for tubercle bacilli have always been negative. Tuberculin test: After an initial dose of ½ mmg. of Koch's old tuberculin there was no reaction, the latter appearing, however, after the injection of one mmg. The Wassermann reaction was negative. The urine was normal. The blood presented a true picture of a secondary anemia.

I am greatly indebted to Dr. S. Wachsmann for his assistance and for his kind permission in allowing me to publish this case.

By SIGMUND EPSTEIN, M.D.,

NEW YORK.

CLINICAL ASSISTANT, ORTHOPEDIC DIVISION, VANDERBILT CLINIC.

Some of the orthopedic surgeon's optimism is inborn, some is acquired in the course of his daily routine. One hears flat-foot patients report prompt improvement in locomotive ability after their first visit so often that eulogies become as customary as passing of the time of day; a series of patients will thus tend to increase the size of one's hatband. Flat-foot in its simplicity being a deformity, that permits a defective distribution of the stress and strain on the structures of the ankle and sole, its correction is usually a simple matter—just the antithesis of the general run of complaints, organic diseases, and disabilities that make up the average work of the general practitioner. Medicaton is unnecessary, no sacrifice on the organism is called for. This cheerful preface to my remarks, gentlemen, is made with a thorough knowledge

Right Congenital Flat-foot in an Infant.

that physicians are skeptical, and require demonstration of the actual curability of weak foot. This I shall attempt to furnish. The orthopedic path is occasionally strewn with thistles; the orthopedist must needs combat other evils than patent medicine and Christian Science—he must contend against the magic shoeman, the purveyor of foot-props, and the osteopaths. The ethics of our profession demand our doing good to the greatest number, and then saying nothing about it for newspaper dissemination.

Our youngest patients are those with congenital flat feet; the best period to begin treatment here is, as Dr. Sayre said, "as soon as the baby is washed." A little baby was cured by a few applications of plaster of paris by the attending physician in a nearby town. The first-born of the same family had been ushered into the world with a similar deformity. I put on one plaster that cured in about four weeks, and furnished instruction which the accoucheur put to good service at the next visit of the stork. Both children are perfectly straight now.

*Read at the January Meeting of the Yorkville Medical Society, Jan. 5, 1911.

The common variety of clubfoot, or equinovarus, contrasts with this in being strongly resistant to correction, in the general run of cases. In congenital splay-foot the heel is well formed, easily brought around to a position of inversion, and thus easily corrected. In a series of about 30 cases Stern of Cleveland reported the average duration of treatment to be about two months.

The general practitioner sees a great deal of rickets, rendering a description of the rachitic flat-foot therefore superfluous in a communication of this sort. A word as to treatment, however, may not be amiss: A shoe built up one-eighth inch on inner side should be used. It might be wise in passing the subject of rachitic flat-foot to lay down several well recognized facts: (1) That knock-knee and flat-foot usually are coexistent and that coxa vara should be suspected and receive appropriate manipulation. (2) That the "corset shoes" are harmful as well as useless, restricting by their stiffness and weight the normal motions of the ankle. The frequency with which rachitic deformities are brought to us decorated with this stiff, function-retarding footwear is the only excuse for this attempt at sermonizing.

Children brought for delayed walking, among other delayed functions, can be often noticed to have a well marked outward turning of the foot. Characterized by a more or less general weakness of muscular tone, these children can do little more than sit or crawl on their haunches; when put on their feet, the knees give way from weakness. Knee-jerks and mental examination are negative. The proper treatment in a case of this sort is an ankle support (brace) with leather padding over the scaphoid bone, serving to push the foot inward, or adducting it. Prognosis is always good unless some mental or spinal defect coexists.

How often is a doting mother, in watching her offspring take its daily bath, worried by its so-called "lack of arch"! A few words of sensible explanation describing the fatty pad supporting every infant's plantar arch-tissues, which persists until the sixth or seventh year, will go far toward avoidance of useless apparatus.

Another popular fallacy is seen in the grandmother's admonition for her young hopefuls to toe-out. If Nature gives us feet that turn in or act best when held parallel to the direction traveled, why make your children walk with their toes turned out, in a position of weakness and awkwardness, impairing the walking function, and inducing flat-foot and round shoulders?

The paralytic flat foot of infantile paralysis has probably attracted the attention of all family physicians in the past few years. The recent epidemics in New York and its environs, the marvelous work of Flexner, and the taking up of the subject by the daily press have helped us to make the diagnosis at an earlier period of the disease. Most of us present will suspect it, where twenty years ago well-trained clinicians gave iron for "anemia" to children palsied by this affliction. The diagnosis in cases after the febrile stage is easily made by the history, by the loss or diminution of knee jerks, by the isolated muscle groups affected, and by the deformities. A "stitch in time saves nine"; yea, but a little splint applied here at the proper stage saves years of crippling invalidism. I believe in the early application of apparatus, especially plaster of paris, to correct contractures, to

put patients on their feet at an early period, and in the administration of ascending doses of strychnine. The further treatment of such weak drop-feet involves a discussion which can be reduced to lowest terms in three words—mechanotherapy, massage, and braces. My electric battery is rusty from age and disuse.

The Flat-Foot of Adolescence.—When a boy or girl reaches the age of 12, the nervous, muscular, and osseous systems are one and all sensitive to the slightest defects of environment, development, or strain. The weak ankle or weak foot is especially prone to occur at this time. The boy grows fast, his ligaments and tendons are succulent—easily stretched. His activity leads to an occasional sprain; his shoe may be short. Girls often are made to wear heels that are not broad enough, they are easily tipped over, and they turn on these unstable props. The muscles and ligaments (especially the annular ligament) on the inner side will stretch, the foot unconsciously assumes the abducted or everted, turned out position, and over and over again the tibials are stretched. Then the mischief commences; if one foot hurts when bearing weight, its fellow takes extra work upon itself, instinctively. More weight is borne, and this second foot becomes unduly strained. The more rapidly weakened arches seem, in my experience, to occur in young boys or girls sent out to work at tender ages, about 14 or 16. The long hours in grocery or drug stores or markets, where boys work long hours, standing on their feet, help to predispose the foot to vicious strained attitudes. In females, the errand girls and salesgirls in the larger stores seem to form the bulk of our applicants for relief from pain in the feet, heels, and calves. These aches are relieved by resting, are least in the morning, and worst during the busy shopping hours. They are made worse by walking over cobblestones, wearing low ties or pumps. I have seen a consecutive series of cases of this kind during the past summer that could be directly traced to the fashion of wearing the dainty high-heeled or suède slippers that then prevailed, when the poorest factory worker seemed to be able to afford this type of footwear. A recent report by the supervisor of a girls' department of Cornell University traces the cause of a goodly portion of the ailments that were seen in the college infirmary, to various conditions. Among the most easily remedied she classed in her summary those due to "overplay" instead of overwork. About a score like this are seen by me every month in young women who walk when unduly tired—who take up physical education when not fitted for it. Others that I put down to overplay are students of various "folk-dances" that have lately come into vogue. Several hours in an afternoon spent in tip-toe gyrations in "gym," on a foot that has been previously weakened by a sprain or a tenosynovitis, go far toward weakening the weight-bearing structures of a delicate girl's foot. It is curious to note here the effect of widespread advertising on the lay mind in private practice—over and over again the history will begin thus: "My feet hurt dreadfully. I have tried all sorts of arch props, I have worn So-and-So's magic shoes, and am getting worse."

Excessive sweating is not an uncommon complication in this type of case. Corns and calluses help to make the patient miserable—varices occasionally are seen in the older unmarried type of women who are self-supporting—frequently seen in this advanced stage of civilized city life. Rheumatism and synovitis can be merely glanced over, not being within the scope of this communication. The general practitioner, seeing these cases first, is frequently to blame for not assuming the direct responsibility of effective treatment at this time. He often sends the patient to a shoe store or boot-maker with a note mentioning the diagnosis and signing his name thereto. The shoemaker does what he believes lies in his province—makes a shoe that looks well, has a stiff inner counter reaching to the ball of the foot, and the patient goes on her way rejoicing, until the counter flattens out from pressure or moisture; the conditions of stress and strain at the ankle still persist and stiffness ensues. At first a peculiar spasmodic rigidity prevents straightening of the foot—an adaptive muscular tightening in the abductors such as the peroneus longus and brevis, or the tendo achilles. Later adhesion of the subastragaloid joints complicate the deformity and make its correction more difficult.

The prognosis is good. Treatment consists in a careful consideration of each case, its signs, and symptoms; as a rule, a foot that can be over corrected without any difficulty is strapped, the shoe is built up, and exercises are ordered. Tip-toe standing a hundred times a day in the pigeon-toed position is a good exercise. The weakened tibials receive particular attention. A physical instructor helps us a great deal in clinic practice by instructing each patient to sharply invert feet and spread the knees, in coming down on the heels from the tip-toe position. The pendulum machines have been a useful adjunct in my experience during the past year. To patients out of town I advise a portable foot exerciser, which has the advantage of being cheap. As soon as the patient's sensitiveness in the plantar region or heel difficulty has cleared up somewhat, a Whitman flat-foot plate is invariably applied, and uniform success has met with my efforts. The critics or improvers of this form of plate have done little more than to show their inability to properly prepare the cast for the mechanic.

Occasionally an adolescent flat-foot will have become so rigid before coming under observation that a *brisement forcé* under an anesthetic is indicated. A carefully applied plaster of paris bandage is then put on the inverted and adducted foot as far up as the knee, and the patient is instructed to walk on it as soon as he is able. This is worn for six weeks, a period in which the former painful condition is replaced by entire relief from pain. After removal a cast is taken and a plate is made and worn for a long period. A certain cure can be invariably predicted, if treatment and after treatment are conscientiously carried out.

A few words as to mechanotherapy will now be in order. As a supplementary method of treatment it takes first rank. Indicated in moderately rigid, but not entirely ankylosed, tarsal joints, daily systematic exercise in the flat-foot machines has given greatest aid to my female and adolescent patients. The principle involved is in the main a methodical, repeated resisted movement performed in such a manner as to exercise the weakened invertors of the inner side of the leg and foot. Any machine or exercise if properly carried out will bring about this result. Pendulum machines are most popular in Europe, where institutes and sanatoria are elaborately equipped. Pivot machines are cheaper and are easily sent by express.

Dr. Bradford of Boston has devised an arrangement of pulleys and weights to furnish the resistance required for active motion of the adductors of the foot.

With the child-bearing woman, modes of life and new activities bring on a new variety of pathological conditions of the feet. Varices and phlebitis show themselves more frequently and call for prompt relief; not a few women arise from their childbed in a much weakened or anemic state; their muscles and ligaments perhaps flabby and inelastic as a consequence. Carrying their children may be a hardship, extra household duties are entailed, and the overburdened, weakened foot turns outward, abducts with its attendant symptoms of pain. Weight bearing in abducted position means ligament strain. Caring little for her own symptoms, the feet are neglected, bunions and corns complicate the situation. The properly managed case is supervised with detailed instructions as to amount of rest, the performance of regular exercises, a properly constructed and built-up shoe, and a pair of flat-foot plates. For temporary treatment, most satisfactory results are obtained by plaster strapping of the foot. This is applied directly to the skin of the sole, ankle, and leg by means of several strips of zinc oxide plaster. Two-inch-wide strips extend from the external malleolus of the strongly inverted foot, under the sole over the inner side of the ankle, and up the leg to just below the knee. Retaining transverse straps around the calf and ankle are placed at a level of the fibular head and over the malleoli. A narrower tape is wound in a figure of eight around the ankle and sole in such a manner as to keep the foot adducted. This holds the foot strongly in its overcorrected attitude, gives great support to the stretched tarsal and annular ligaments, to the great relief of the sufferer. To insure proper adhesion a gauze bandage may be applied over this, but if intelligently put on the dressing is good for a week or ten days without it. If complicating varices are detected, I use either a flannel or crêpe bandage, with happy results. During the time the straps are worn it is not wise to bathe the feet often in hot water on account of the tendency to loosen. In clinics where patients are given plates of the ordinary (shoe-store) type at the first visit, my observations have led me to use the strapping constantly in flat-foot cases. The benefit derived is brought about by a support not of the arch alone, as is commonly supposed, but by a gripping of the malleoli, sustaining the annular ligament admirably. It has recently been shown by Dr. Rugh, of Philadelphia, that this strong fibrous band acts somewhat like a ring, giving circular firmness to the tendons of the leg muscles at the ankle. The "snatch-block," employed for holding ropes, that riggers use a good deal, furnishes an analogy. These details are mentioned, for when once the principles of strapping for flat-foot are appreciated, it makes no difference how the strips are put on. As soon as one effectually supports the strained anatomical elements the relief sought is given.

As to the period through which the treatment is carried out it might be said to average two weeks. As soon as most of the symptoms of pain and tire disappear we make a plaster model of the foot, which, when properly trimmed, is ready for the brace maker. As the shoemaker sticks to his last, so does the orthopedist stick to his part of the mechanics of the treatment of flat-foot. A paper pattern is then made to get the approximate size of the finished plate, and the pattern pasted on a sheet of steel, about 19 gauge; this guides the mechanic's drill or scissors in cutting out the plate on the flat. After suitable heating, the plate is hammered and carefully approximated to the cast and is finished when plated. We have found that tinning makes the best wearing finish. Rubber vulcanizing breaks, nickel rusts too easily, while chamois covering is usually uncomfortably moist.

Just as a properly adjusted plate gives comfort, even so can one improperly adjusted cause the greatest distress when the body weight is borne. Experience teaches that most often the cause of failure is an improperly selected patient for the treatment, or an improper diagnosis. I have seen well made instruments cause the distress in tabes, Raynaud's disease, and incipient perforating ulcers of the foot.

It is an ordinary experience to find arch props doing harm in cases injudiciously diagnosed as flat-foot; for example, plantar neuritis or tuberculous tarsal disease. Here time is lost by improper treatment, but, as a rule, no injury is done. In selecting a case for a plate as described it is manifestly useless to apply a tightly fitting appliance that corrects and adducts, upon a rigid, or inflamed, or swollen ankle, upon one complicated by a periostitis as in gonorrhœa, or in cases accompanied by bursal enlargement. A little care and study will usually guide the surgeon to the easiest horn of the dilemma. Prescribing a flat-foot plate is just like sending the apothecary a note to give bearer or patient calomel—leaving the dosage to him. Of course, my hearers would not think of such a thing; yet ordering an instrument whose size, shape, and thickness are decided by the mechanic is quite as serious a shirking of the responsibilities of the attendant.

Corns and bunions are efficiently treated by a proper shoe in the average case. For the metatarsalgia one can apply a felt pad about an inch wide and two inches long to the ball of the foot, strapped with adhesive plaster.

The complications of flat-foot that may be troublesome are the various forms of arthritis. A writer, a few years ago, made the assertion that "rheumatism of the feet is as scarce as snakes in Ireland." He seems to have overshot the mark in attempting to draw attention to the frequency of flat-foot as a cause of the tired aching pains of the heel, inner side of ankle, and calf. My observations lead me to believe that many acute articular rheumatisms get well of every joint symptom except a tender swollen deltoid ligament—a condition rather frequent in unacclimatized young servants. Prompt results have followed the treatment outlined.

The arthritides of infectious origin need be only mentioned in passing; the importance of careful examination of their portals of entry cannot be overestimated. A swollen, tender, non-tuberculous tarsus, especially if toes and heels share in the process, should lead to a scrutiny of the gums, tonsils, and teeth. The bowels and genital tract often furnish the key to an ankylosed foot.

At the menopause women seem to be more prone to arthritis deformans as a complication of flat-foot, than any other joint change. It has recently been shown that vascular changes so common between 40 and 60—obliteration, calcification, and thickening of smaller arteries—have much to do with the inciting of these changes.

GASTRIC ULCER PERFORATING INTO THE COLON.

By M. GROSS, M.D.,

NEW YORK,

ATTENDING GASTROENTEROLOGIST TO THE MOUNT M[illegible] HOSPITAL.

Perforation of a gastric ulcer into the colon being a rare occurrence, a description of the clinical symptoms in the following case may be of interest.

L. R., male, forty-six years, married, skirt operator. Family history, negative. Personal history: Had typhoid fever at the age of eight; otherwise always felt well; of moderate habits.

Present ailment. Nine months ago he suddenly fell ill, becoming unconscious about two hours after an ordinary meal. On regaining consciousness he vomited blood, aside from a large quantity of food. The blood was partly mixed with the stomach contents; there was also freed fluid blood and large coagulated clots. Hardly two hours after the hematemesis there were a few soft evacuations, although previously he had rather been constipated than otherwise. Black, coagulated blood was mixed with these evacuations, which continued for several days longer.

Fig. 1.—Showing the outlines of the stomach and duodenum, and the beginning hourglass construction in the fundus portion of the stomach.

A few days before the attack the patient had painful sensations in the left hypochrondrium, with radiations to the left and upward.

The presence of macroscopically visible blood in the stools at a comparatively early time after the hematemesis is particularly noteworthy here. (Oozing of blood after the perfected perforation?) About two months later the patient had a similar attack, which, however, took a somewhat milder course than the first.

Up to a week prior to his admission into the hospital, which took place January 24, 1911, he felt pretty well, although he had not quite recovered from the second attack. What brought him to us were "premonitions" of a new attack; the pain in the left hypochondrium reappeared, solid food caused pain, localized at a definite point, radiating toward the cardiac region.

Physical Examination — Patient is somewhat anemic, result of general examination negative, with exception of a slight albuminuria. No traces of tuberculosis or syphilis. Temperature was always approximately normal.

Blood Findings—Hemoglobin, 44 per cent.; red blood corpuscles, 3,500,000; white blood corpuscles, 15,000; polymorphonuclear cells, 83 per cent.; lymphocytes, 17 per cent.

Abdomen—Soft, not tympanitic. Under the left costal arch we found on inspection and palpation a "fulness" which was slightly susceptible to pressure. It may here at once be mentioned that, when patient was discharged from the hospital about three weeks later, this "fulness" could no longer be detected, not even in a hot bath. (Induration of ulcer and infiltration around it?)

Stomach Contents—No contents obtainable on an empty stomach. The lavage water, introduced immediately afterward, had, when withdrawn, a distinctly fecal odor, contained little mucus, red blood cells, and no food remnants. One hour after ingestion of Ewald's test breakfast no more than 4 c.c. of the contents could be recovered, which were bloody tinged and of fecal odor. Congo negative, blood (aloin) positive, a few food remnants and a large number of Boas-Oppler bacilli.

A second examination, made within half an hour after the ingestion of Ewald's test breakfast, yielded scarcely 30 c.c. of stomach contents of the same character as on the previous occasion. Lactic acid (Strauss) was distinctly present.

On the third day after admission, at about 6:30

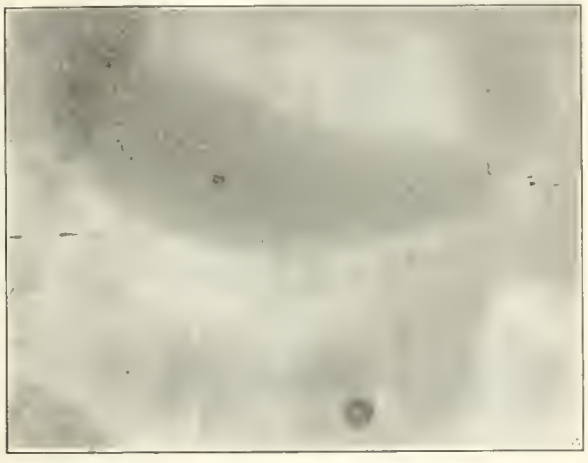

Fig. 2.—Showing the outlines of the stomach, part of the duodenum and colon transversum, and a loop of the splenic flexure in close proximity to the construction in the stomach and covering it.

p. m., patient, who had apparently been quite well, suddenly became unconscious and collapsed. On regaining consciousness he complained of great sensitiveness in the gastric region.

Stomach Region—Distended, rigid, and sensitive. Liver dullness not obliterated. About fifteen minutes later the patient vomited a pint of light red fluid blood. Macroscopically visible blood with the feces did not occur this time, which may possible be due to medication.

Epicrisis—We had from the first entertained a suspicion of a subsisting gastric ulcer, probably located at the fundus and the posterior wall of the stomach. The fecal odor which escaped through the stomach tube and furthermore the distinctly fecal odor of the stomach contents, rendered it from the first very probable that the ulcer was a perforating one and that the perforation had taken the rare direction toward the colon. Communication with higher intestinal ansae would not give rise to the fecal odor.

In serpiginous ulcers and scar formations, with impeded peristalsis and the consequent distension of the stomach, there may be putrid gases, even in the absence of a perforation. In the present case,

however, the conditions had not advanced to that extent, as was confirmed by subsequent examinations. On the other hand, there is no doubt that the decomposition of the blood coagula and the products of disintegration may also have produced the putrid odor of the contents of the stomach, but there was besides on all occasions the unmistakable fecal odor.

The examination of the stomach contents points to the possibility of carcinoma having grafted itself upon an ulcer, but that the latter had existed first was shown by the active course of the disease and the comparatively rapid recovery of the patient even after an abundant loss of blood. Nor would the findings of the stomach examination point conclusively to secondary carcinoma, at least not at this period, because patient begins to show prompt recovery even after this last attack, and the course of the disease in this class of cases should always be taken into consideration, but the mere increase in weight would not speak against carcinoma.

Up to this point, however, there was no *direct* proof of the presence of an ulcer perforating into the colon, and in order to clear up the matter, if possible, the following experiments were made. Patient was given a high enema of carmin red solu-

Fig. 3.—Showing the outline of the stomach and duodenum.

tion. After ingestion of a glass of milk the stomach tube was introduced, and from time to time the stomach contents were withdrawn on the assumption that the milk in the stomach would be colored red if there were the slightest free communication between stomach and colon.

The stomach contents thus withdrawn again had their distinctly fecal odor and they also had a reddish tint, but as at the same time blood coagula were macroscopically visible in the milk, we could not come to definite and unmistakable conclusions. A second experiment was made about two weeks later for the same purpose. Patient ingested a glass of aqueous iodine solution (1:5,000) and immediately afterward received a high starch enema, the colon having been thoroughly cleansed. From time to time intestinal contents were withdrawn and examined for blue discoloration, but with a negative result. A chloroform test for the presence of iodine in the intestinal contents was likewise negative.

We are nevertheless justified in interpreting the *clinical* symptoms as pointing to a communication between stomach and colon not only on account of the fecal odor of the stomach *air* and the stomach contents, but also on account of the fact that hematemesis was followed in a relatively short time by bloody stools in the first attack. Furthermore, I am rather inclined to regard the carmin test as positive. However, if our assumption is correct that there is a communication between these two organs, the probability is that the perforation is so minute or so hidden that a free exchange of *contents* could not have taken place (there never was lienteria), although intestinal *gases* could find free access to the cavity of the stomach.

As patient objected to operative interference, a number of radiographic pictures were taken, for which I am indebted to Dr. L. G. Cole.

Successive pictures were taken of the stomach alone and of the stomach and colon, filled with bismuth mixture.

The very first picture showed a distinct indentation at the fundus, corresponding to the splenic flexure. In order, however, to exclude accidental errors, such as might be caused by peristaltic movements, etc., a number of successive pictures were again taken on two different days, all the photographs showing the same result as illustrated by Fig. 1.

From Figs. 2 and 3, showing the posterior aspect, the colon filled with bismuth, it will further be seen that the left flexure of the colon lies closely to the indentation, in fact seems to be drawn into the constriction at the fundus of the stomach. In this illustration, however, the indentation itself is hidden by the filled colon. These radiographic pictures, therefore, reveal a beginning constriction of the stomach caused by an ulcerous scar, and a beginning development of an hourglass stomach, with adhesions to the colon at the place where the perforation had probably taken place.

It may be assumed with tolerable certainty that the perforation took the following course: The ulcer penetrated down to the serosa and the resulting inflammation—perigastritis—spread to the neighboring colon, resulting in close connection between the two organs, the adhesions preventing perforation into the free abdominal cavity. The perforation seems to have occurred suddenly in this case, certainly without giving rise to distinct prodromal symptoms.

I wish to take this opportunity to express my thankful appreciation of the assistance rendered me by the house staff of the Mt. Moriah Hospital.

315 Second Avenue.

HABIT, THE JAW, AND CHARACTER.

By JAMES J. WALSH, M.D., PH.D., LITT.D.,

NEW YORK.

DEAN AND PROFESSOR OF NERVOUS DISEASES AND PHYSIOLOGICAL PSYCHOLOGY AT FORDHAM UNIVERSITY SCHOOL OF MEDICINE.

When your committee asked me to address your society at its annual meeting I felt that their only reason for doing so must be that I should say something of the influence of habits of various kinds in producing deformities of the jaws and teeth. I accepted the invitation because I believe that there is nothing that physicians and surgeons and dentists need to understand better than the rôle of habit in the production of many ailments and even many changes in tissues that might seem to be due to much more serious pathological conditions at work. Pains and aches of all kinds and especially those grouped under the term rheumatism come under this head. Hence my readiness to try to help to

*Read before the American Society for Orthodontia at the New York Academy of Medicine May 26, 1911.

the understanding of the mental elements in many of your cases.

Long before physiognomy advanced to any pretensions to be that classified knowledge with deduction of principles that we call a science men had noted that certain shapes of faces and certain types of heads went with particular characters in humanity. Toward the end of the eighteenth and beginning of the nineteenth century Lavater, by his studies in physiognomy, and Gall by his investigations into brain anatomy and the relations of the brain to the skull and the head generally, called emphatic attention to how much the intellect and with it that other power that we call the will were coordinate to certain shapes and sizes and types of the bony conformation of the head. Their work did much to call more particular attention to what had been a subject of general observation for almost as long as the history of mankind runs. For men have always recognized that large foreheads, broad skulls, and especially broad jaws, provided they were not the result of deformity, meant for the power to rule self and others.

I have here a portrait of Cheops, whose name in his own language was Khufu and who is known now to have been the builder of the great Pyramid at Gizeh in Egypt. May I recall in the words of an Egyptian historian that this pyramid is the greatest mass of masonry that has ever been put together by the hands of man, rising from a base covering thirteen acres to a height of 450 feet. According to Herodotus 100,000 men were employed for twenty years in its erection. Until we got to know something about the man this looked like a stupendous work, accomplished merely by a great slave-driving monarch. He was, however, the greatest of the kings of the Fourth Dynasty who reigned at Memphis, and the more we have learned about him the more we have come to appreciate the fact that he was a great warrior, a great administrator, a great ruler of men, and that this immense monument to him, which has come down to us, represents only another phase of his power to do things magnificently. Fortunately for us a portrait statue of him has been recently discovered, that is within the last ten years, and we may now look upon the features of the man who ruled the men of his time with an iron hand and did things that are even the wonder of a modern world with mechanical contrivances that make such accomplishments easy.

Flinders Petrie, the great English Egyptologist commenting on his picture, says, "The first thing that strikes us is the enormous driving power of the man, the ruling nature which he seems impossible to resist, the determination which is above all constraint and all opposition. As far as force of will goes the strongest characters in history would look pliable in his presence. There is no face quite parallel to this in all the portraits that we know—Egyptian, Greek, Roman, or modern." As I pass this round you can see for yourselves the breadth of jaw, the firm, full and yet not over full lips, the breadth at the cheek bones, indicating how wide is the skull at this point and the suggestion of the fulness of the bosses of the forehead, concealed even though they are by the cap that he wears. I think that any of us would agree that Prof. Flinders Petrie's expressions are not exaggerated and that one can see at once that you have here the portrait of a strong-willed man who will not brook opposition and who will not only set things going, but see that they are kept going.

If you turn over the next page of that history you will find another portrait statue. It is said to be one of the masterpieces of Egyptian sculpture and represents one of the overseers of the work on the Great Pyramid. Like his master, King Khufu, he looks as though he would be able to drive men.

It would not be difficult to illustrate the opposite state of affairs, that of the men with narrow-pointed chins who have worked harm in the world's history. They are not rare among the portraits of Egyptian kings that we have and they are frequent among the Roman emperors, especially of the earlier and the later years. It is no wonder then that mankind is agreed on the jaw as representing character. There are, of course, certain patent peculiarities in association with this. We talk of thick lips as representing sensuality and, of course, our reason for doing so is that we have come to know by observation and experience that usually the sensualist has these features. When there is a combination of a narrow chin and thick lips then we very often find not only a tendency to sensual indulgence of some kind or other, or perhaps of several kinds, but also, as a rule, a lack of control that leads or may lead to excesses. We must not forget that sometimes there may be behind these outward appearances a power of will that completely vitiates the conclusions that we might draw from them. When Socrates was told by a Greek physiognomist in the presence of his pupils that he had many vices, the pupils were so impatient that they would have hurt the poor physiognomist in their vexation at his accusations of their beloved master. Socrates himself, however, insisted that the man should be let alone, because he was telling the truth as to what he, Socrates, would have been without training and control of himself. Similar stories are told of such men as Ignatius Loyola, founder of the Jesuits, and others of the really strong characters of history in spite of the physiognomonica peculiarities that seemed to condemn them to criminality.

We used to think that these conditions of physiognomy, especially the narrow jaw and the full, thick lips, were congenital, due to the nature of the individual and that, therefore, it was simply a matter of making the best of them. In recent years, however, we have come to realize that while there are congenital elements in some of these cases, most of them represent conditions acquired from the functioning of the mouth and the jaws. The rolling full lips occur particularly in mouth breathers. The process of breathing through the nose is easy and natural and develops that organ so as not to leave it narrow and thin and incompetent to fulfill the function of drawing in all the air that is needed. Mouth breathing, on the other hand, requires effort and leads to overgrowth of the lips and their turning outward. With the discovery by Meyer, the great Danish physician, of the rôle that adenoid growths in the pharynx and occlusions of the posterior nares play in the causation of mouth breathing, or rather in the prevention of nasal breathing, a great light was thrown on the whole question of changes in the face consequent upon the function of breathing. This action of respiration repeated from fifteen to twenty-five times a minute all during life can, of course, produce, as will readily be understood, rather striking effects upon the organs connected with it.

We are learning more and more to appreciate, especially in medicine, that while we used to blame nature for a great many things and consider hered-

ity as a very baneful factor and proclaim it as the source of many disadvantages to humanity our opinions in what seemed often the plainest cases, were founded on insufficient information. Josh Billings used to say "It is not so much the ignorance of mankind that makes them ridiculous as the knowing so many things that ain't so." We certainly thought we knew a heap of things with regard to heredity that were not so. As the French say, "we have changed all that." We know now that tuberculosis is not hereditary but contagious. We know that many difficulties in the respiratory passages are due to the irritative overgrowth of tissues that are meant to protect us and not to any inheritance or natural acquirement of a defect. We know that the conformation of the mouth and the nose depends to a great exent on the conditions during early extrauterine life rather than on the state at birth. We have learned the lesson that nurture is more important than nature. By nature we mean what comes to us from our parents, while by nurture we mean the modifications produced in the organism by the conditions surrounding it from the moment of conception until it reaches its full development, say at the age of 21 or 22. Nature we cannot modify, but nurture we can often alter to the decided advantage of the individual.

We have learned by observation that character is expressed by a broad jaw. We have learned, however, also, that a broad jaw depends on certain physical factors in a great many cases. Bony development depends on muscular use to a great extent and then on the action and reaction of exercise. When, for instance, a child has a lame leg the side of the pelvis above it does not develop properly. Growth is not merely a matter of provision of nutrition, but is the result of reaction to stimuli. Members of families that do not work much or take much exercise gradually acquire the delicate bony frame of the aristocrat, which leaves him at the mercy of the muscular force of the workers. A physician is always anxious about the shape of the pelvis of a woman, one of whose legs is seriously deformed because it is almost sure to be undeveloped, and this will be serious where parturition comes. What is thus true of the heavy bones of the trunk, and particularly of the pelvis, seems to be true of the skull generally as well as of the jaw bone. Unless the mouth is held firmly closed by muscles in constant activity the jaw does not develop properly, hence the mouth breathers' lack of breadth of chin as a rule. If the jaw does not develop well the skull itself seems to lose some of its development because it is not pulled upon and stimulated by the muscles that move the jaw.

These serve to develop particularly the anterior portion of the skull and its base. It is in these portions of the skull that the most important parts of the brain so far as character and intellect are concerned are situated. It always seems to me particularly important that the base of the skull should be well developed, as if somehow this permitted a better development of the connections between the higher cerebral centers and the lower centers as well as the peripheral nerves. Of course I understand how theoretic are such considerations. I am trying, however, to connect our every-day observations in human physiognomy with what we know about tissue development and the place of the brain as the ruler of the body. Narrow-chinned people are usually lacking in character Is it not probably so because the jaw has not properly exercised a stimulus upon the skull to bring about sufficient development of it in order to permit of adequate brain development? We are apt to think of persons who go round with mouths open as not having much sense. The hanging over-full lips are considered to represent the animal side of man, and the typical intellectual man has a firm, well-shut mouth. Must we not take all of these things, anatomy and function, together in order to try to understand them?

While, then, we have been rather accustomed to think of improvements in the mouth, what you have grouped under the word orthodontia, as only of cosmetic value, or to put that Greek word into Latin of ornamental purpose, it is evident that especially in the younger years they may have a magnificent hygienic and even intellectual purpose. Children must not be allowed to be mouth breathers, and anything that interferes with free nasal breathing must be seen to. This is not the place to dwell on phases of this, but I may mention that irregularities of the septum in the nose, the presence of tumefied turbinate bones and of adenoid growths in the naso-pharynx must be corrected. Anything that interferes in any way with the proper growth of the jaw must also be carefully attended to. We all know very well what serious effects can be produced by so simple a habit as thumb sucking. The ugliest kind of protruding jaws, with teeth at the animal angle and with the creation of a condition that almost makes it impossible to keep the mouth shut, may develop. It is sometimes suggested that the thumb suckers must not be considered as having injured their development by their habit, but that their habit was rather the result of a lack of mental development. I have known some cases, however, and I am sure that they are familiar to many others, in which this was not true. Two persons particularly I recall in whom it was extremely difficult to break the habit of thumb sucking, yet it was accomplished and they are among the brightest people that I know with plenty of character and will-power.

Human nature is prone to be the victim of habits. Habit, according to the old phrase, easily becomes second nature. We must not forget that there are many habits not nearly so noticeable as thumb sucking that may produce deformities of the mouth and especially of the teeth and may as a consequence make it difficult to shut the mouth. If mouth breathing then develops there may be loss of development in the jaw and consequently also in the skull. Children have been known to keep constantly pushing their tongue against their teeth whenever they were abstracted. Of course to the ordinary person unfamiliar with the extent to which habit may go it would seem impossible that this could produce any serious results. The tongue is composed of rather vigorous muscles however, and if these are strengthened by vigorous pushing exercises as the consequence of a habit serious results may be produced on the front teeth and such results have actually been noted.

It is only when one has seen what havoc such a habit, for instance, as the biting of the nails can play with the appearance of the ends of the fingers in inveterate cases that one is able to realize how much of detriment can be worked in spite almost of the patient. Everyone has seen tics, winking, frowning, grimacing, nodding, twisting movement of the hands and the like, but few realize that these are merely habits, and though they make the patient so uncomfortable and so noticeable

and make him want so much to correct them they can continue in spite of him. We are likely to think of tics or habit spasms as mainly external, but within the oral cavity particularly there are a number of curious habits that may be formed. Some people cannot keep from biting the cheek, some cannot restrain sucking in their lips in curious ways. Some execute movements of the soft palate and some of the swallowing muscles that become veritable tics. I have seen two cases in which somehow patients had acquired control of a muscle in relation to the Eustachian canal so that a distinct clicking noise was repeated several times a minute during all their waking hours. Any of the movements of muscles associated with the mouth, whether internal or external, are likely to have an effect upon the jaw if they are formed during the plastic developmental period. They are interesting to dentists then because on the development of the jaw depends the proper development of the teeth.

The various tongue movements and sucking movements are particularly important. Children sometimes acquire the habit of shutting their mouth tight and drawing in their cheeks. When they do this a dozen or even two or three dozen times a day it may not make very much difference; if it once becomes a tic however, and is repeated once every minute or two during all the time when they are not actually eating or talking it is easy to understand what an effect it may have upon the jaw. Sucking inward movements of the anterior lips are likely to produce the same effect and they have been noted as occurring in children who exhibited certain curious malformations. In the days when we used to think that the teeth grew as they would in spite of anything that we could do, it would have been hard to persuade men that such apparently trivial movements could affect bony structures. Now that we know that the teeth can be moved asunder or closer together by a little piece of rubber and that this will readily bring about many changes in their relations to one another, it is quite easy to understand how habits of the tongue, the cheek, or the lips frequently repeated will produce even serious deformities in the growing child whose bones are not yet thoroughly hardened and the growth of which renders them particularly susceptible to such influences.

Then comes the question as to what is to be done in such cases to prevent the habit from doing harm. You who study orthodontia have seen the effects and are learning to correct them. Like every other branch of the medical profession, however, you would much prefer to be able to prevent them. I may say at once, from the standpoint of the psychologist and physician who has often tried to bring about the breaking of the habitual movements we call tics, that it is sometimes an extremely difficult matter. It would seem simple enough to keep a woman, and above all a young woman, from biting her nails, seeing that hands may be objects of beauty and may thus become very ugly. There are a great many young women, however, who simply insist that they cannot break themselves of the habit. What they mean is that it is performed unconsciously and that in certain moods their fingers go to their mouths, they chew at their nails, and the sensation is so habitual that they do not notice it until some damage is done. What is necessary as an aid to them is to bring the action above the threshold of consciousness. This can be done by keeping on the ends of the fingers some harmless bitter preparation, aloes or the like, that warns the patient that the fingers are in the mouth. As a rule, if they are determined to break the habit and are thus reminded they are able to do so. Often it is of great help to have someone near them who reminds them gently and helps them to break themselves of the habit.

With regard to habits in the mouth it is not so easy, though here, too, anything that will remind patients of what they are doing is of help. For children the direction of someone else is almost necessary. As they get a little older the fact that they are doing the habitual actions may be brought into their consciousness by the insertion of a piece of rubber between the teeth at the point of offense or by various expedients that dentists would be able to invent and suggest. The important thing is to have the habit produce some unusual sensation. This unusual sensation brings the action above the threshold of consciousness and helps to break the habit. Often the formation of a contrary habit of some kind is an excellent remedy. Children who have the habit of sucking in the breath should be taught to blow outward and repeat this action frequently. This of itself might produce undesirable results if repeated too often, but what is done consciously does not become habitual. The practice can be of use in helping to break a habit. Sometimes it helps patients to require them deliberately to repeat actions consciously which they have been doing unconsciously; this disturbs the unconscious habit and helps to bring it above the threshold of consciousness and so leads to its gradual amelioration. No hard and fast rule can be laid down and each individual case must be treated on its merits.

Bloodletting in Pneumonia.—Beverley Robinson states what we should insist upon far more than we do, and especially in private practice when we see pneumonia in the beginning, is bloodletting in the initial stage with leeches, and particularly when there are much local pain, pulse of high tension, and rapidly increasing temperature. —*New York State Journal of Medicine.*

Biological and Therapeutic Action of the Röntgen Rays.—Vittorio Maragliano says that the *x*-rays are essentially a source of disturbance and destruction of the tissue cells, healthy and diseased. The inflammatory action caused by these rays is not primary, but secondary to the products of cellular necrosis. The rays produce cellular alterations which generally do not show themselves quickly, but only in process of time. Their effects are cumulative. They last for a long time and are generally irreparable, or repaired with difficulty. There is a great difference in radiosensibility among the cells of the various tissues, healthy and diseased. The rays act at a distance and by the production of destruction of cells, through secondary rays produced in the tissues. They diminish the defensive powers of the healthy organism against infections. The rays have had therapeutic results in lymphatic leucemia, myeloid leucemia, pseudoleucemia, Hodgkin's disease, Mikulicz' disease, anemia with splenomegaly, pernicious anemia, Banti's disease, diseases of the respiratory system, bronchial asthma, syringomyelia, Graves' disease, and acromegaly. The good effects are due to the projection of minute emanations from the anticathode, which fix themselves on the cells and cause nuclei of decomposition in them. These rays will be useful when they can exert their destructive action on tissues that are injurious to the organism and yet are sensible to the destructive action of the rays, while the normal tissue cells are not injured.—*Giornale di Electtricita Medica.*

CANCER IMMUNITY.

WHENEVER there is concerted action on the part of the medical profession and its natural allies in the study and suppression of the great disease plagues, a multiplication of knowledge is certain to accrue, although the present fruition may not at once be in evidence. Practical advance must necessarily be chiefly along preventive lines, for there is always abundant opportunity for dealing with individual components of a causal nexus. For example the removal of outlived or otherwise useless structures in which cancer develops could hardly fail to diminish greatly the incidence of that malady. But science will always persist in a research for actual curative agencies, with the full conviction that for every morbific agency there must of necessity be antidotes which either destroy the cause, render it inoperative, or neutralize its effects.

Cancer research continues to bring to light new and interesting facts which are often in marked variance with *a priori* deductions. At the very recent session of the German Central Committee for the Investigation and Suppression of Cancer, at Berlin (*Deutsche medizinische Wochenschrift*, June 15), Apolani read a paper on cancer immunity. Figures show that spontaneous mouse cancer occurs in the female almost exclusively, but may be inoculated with equal facility in members of either sex. Spontaneous cancer occurs in elderly mice but inoculation occurs most successfully in young animals. Cancer is much more readily inoculated among animals of the same species. Rats, for example, cannot be successfully inoculated with the most virulent mouse cancers. From the abortive growths which result in the rat, however, mice can be successfully inoculated. This susceptibility and insusceptibility are believed by Ehrlich to rest upon difference in metalbolism. But not only is there a species susceptibility: different breeds and strains of mice show notable differences in this respect, and thus we are brought naturally to individual disposition. Mouse "families" also show different degrees of familial susceptibility.

Acquired immunity is a more elusive subject and the numerous individual observations cannot be so readily elaborated into generalizations. Immunity to inoculated cancer is sometimes attained without in any way illuminating the possibility of immunizing against spontaneous cancer.

A notable parallelism has been alleged to exist between the behavior of mouse cancer cells and that of trypanosomes. When an animal that has once suffered from trypanosomiasis undergoes a relapse, the parasite is seen to have undergone some modifications due to the nutritive processes of the host. We can thereby understand why a cancer cell becomes domesticated, so to speak, in the tissues of a particular species of animal so that it flourishes more readily therein.

There is room for discussion in regard to the parallelism between cancer cells and trypanosomes. While some investigators see a fundamental biological difference between the two, others appear to regard the resemblance as close enough to suggest a relative identity in pathogenesis.

PHOSPHATURIA.

THE uroscopist of a generation ago had at his behest a number of delicate tests for fluctuations in the normal constituents of the urine, as well as for the presence or absence of many abnormal constituents. He was, however, ridiculously conservative, not to say timid, about assigning any significance to his findings. To state that an excess of a given substance or the presence of a foreign ingredient indicated or suggested some visceral or blood or metabolic affection was to declare one's self a charlatan—on a level with the medieval uroscopist who predicated the most absurd things after "casting the urine." The uroscopist in the '70's and '80's recognized the presence of many abnormalities, such as cystinuria, alcaptonuria, oxaluria, phosphaturia, indicanuria, urobilinuria, etc., etc., and entered such terms into his reports. Yet he regarded the entire subject of the meaning of these phenomena as up to his patron, the clinician. The latter used to complain that mere findings without interpretation were practically worthless to him. This state of affairs has been steadily ameliorated, and to-day it is commonly realized that all pathological urine has a definite significance. The uroscopist at least owes it to the practitioner to inform him briefly as to what a certain abnormality has usually signified, without in any way making a definite diagnosis.

An excess of phosphates in the urine, when found a generation ago, was believed—largely on theoretical grounds—to represent increased catabolism of nervous tissue. So far as we know it had no further significance. In order to comprehend what it means to-day, we quote from a paper read by Schlagintweit before the Aerztlicher Verein of Munich (*Berliner klinische Wochenschrift*, May 1). Phosphaturia may be latent or manifest, in the latter case representing a sediment which favors calculus formation. In latent phosphaturia the precipitate appears only when the urine is boiled, and means simply that the lime and magnesium phosphates are thrown out by an alkaline urine in manifest phosphaturia; while in latent phosphaturia boiling causes a decomposition of the soluble phosphates with formation of the same insoluble salts.

In alimentary phosphaturia, which represents a simple, physiological type, the alkaline reaction which makes this condition possible is due to a vege-

tarian diet. A gastric type is due to wasting of gastric juice, such as occurs in hyperchlorhydria, also in hyperemesis. A metabolic phosphaturia is now, as formerly, believed to result from abnormal nerve waste, but to-day is held to be of significance chiefly in neurasthenia. It is by no means constant or pathognomonic. A curious phenomenon is reflex phosphaturia, which is often set up by phimosis, gonorrhea, the passage of a ureteral catheter, etc. Alimentary phosphaturia yields readily to diet, and when the cause of the disorder is waste of gastric juice, the condition disappears with removal of such causes. The same is true for reflex phosphaturia. Metabolic or constitutional phosphaturia, on the contrary, may be rebellious to treatment, although in many neurasthenics the condition is readily controllable. Obstinate cases sometimes yield to mineral acids, but in general the condition is intractable, as if it were part and parcel of a neuropathic constitution. Generally speaking phosphaturia is akin to carbonaturia, and the two are often found side by side. The precipitate of triple or ammoniomagnesian phosphates in an infected alkaline urine is a universal phenomenon, having nothing in common with phosphaturia.

THE PREVENTION OF SOME INFECTIOUS DISEASES OCCURRING IN ARMIES.

Lieut.-Col. C. H. Melville, Professor of Hygiene at the British Royal Medical College, recently delivered a course of lectures on army sanitation, published in the "Journal of the Royal Sanitary Institute," April, 1911. The lecture on the prevention of certain affections, such as typhoid fever and intestinal diseases, is especially interesting. Melville states that the diseases which occur in the field are comparatively few in number, and by far the most important belong to one class, the intestinal. Of these, typhoid fever and dysentery are the most frequent, cholera being a rare army disease in civilized countries and in temperate climes. As a type of the intestinal diseases typhoid fever may be taken as the most serious. Moreover, the preventive measures which are applicable to it are equally applicable to the other members of the class.

The man in hospital with typhoid fever need not be considered to any extent as a probable source of infection, as all the most efficient precautions to prevent the disease from spreading are naturally taken there. Melville points out that it should be rendered impossible for any infection to pass from the feces or urine of a man in hospital, to the air, water, or food of his comrades in barracks or camp. Measures can be more or less easily taken which will effectively destroy the disease germs in feces or in urine. But while the man in hospital is little or no menace to the health of others, the infected man outside is the source of considerable danger. He belongs to one of two classes, viz., those who have the disease, and those who have not the disease. The first class may be again divided into those who are in the early stages of a bad attack, and those who are in the middle of a mild attack, the so-called ambulatory cases. The second class, including those who have not the disease, may also be divided into those who have had the disease, and those who have not had the disease but have been in attendance on patients—for instance, medical men and nurses. Those who can be proved to have had the disease should be isolated from their comrades until it has been demonstrated beyond doubt that they are not carriers. Those men should be the particular care of the medical officer, who should see personally that the excreta are not only covered with earth, but that the trenches are scorched with a little kerosene oil or straw ignited in them every day. Three examinations of the feces and urine, carried out at intervals of one week, with negative results, should be required ere the men are permitted to rejoin their comrades. Further, it is a safe rule to make that no man who is known to have had typhoid fever within the past twelve months, whether he is a proved carrier or not, should be allowed to take any share in the preparation or cooking of food. When a man has been proved to be a carrier there is nothing for it, but to discharge him as unfit for service.

The man who has been in attendance on or living under the same roof as those suffering from typhoid fever, as a rule is little of a menace. The attendants almost invariably belong to the Army Medical Corps, while the number of men who have been living in a house in which typhoid fever has been present is so small that although they should be looked upon with suspicion, they cannot be important factors in the spread of the disease.

With regard, however, to the other two classes mentioned, those who are sickening for a severe attack, or are actually undergoing a mild attack, the case is different. The first of these classes is the less dangerous. The disease will probably be detected in a short time and the victim relegated to the hospital. The management of the other class is one of the gravest problems confronting the army medical officer. The individual may show few signs of the disease and in consequence is most difficult to identify as an infected person. Therefore, it is against this man that conservancy must be aimed. By careful burial of all excreta without exception and safe disposal of urine the danger may be kept within bounds, but, as Melville shows, any carelessness in that respect will mean fresh cases of the disease originating from this one man, each of which in turn during the period of incubation, which may be as long as three weeks, and is usually ten days, will act as a reservoir and focus of the disease. The disease germs lie in the excreta of the infected man, and the most dangerous to the health of others is that infected man who is able to keep on his feet and in whom the disease is unrecognized. As such cases cannot be recognized, Melville is of the opinion that the right thing to do is to look on every man as potentially infected, and to treat his excreta as potentially containing

the microorganisms of entric fever. The only preventive measure which is really effective is the immediate burial of the excreta. This is the one essential of sanitation in camp. The author does not discuss the question of preventive inoculation, the utility of which has been so amply demonstrated in the camps at San Antonio, but considers only the public health measures to prevent the spread of typhoid fever.

The prevention of dysentery is practically the same as that of typhoid fever. An essential point, of course, in the prevention of infectious disease is early diagnosis. In standing army camps of any size there should be small laboratories in which modern scientific methods of blood and serum examination can be carried out. As regards troops on the march this procedure is not feasible and therefore detection of infectious disease is extremely difficult or well-nigh impossible. Every man who is sick with diarrhea, and the malady in camp is very frequent, cannot be sent to the hospital for observation, as he should be sent, as a potential case of typhoid fever or dysentery, for if this were done the army would soon be reduced to the footing of a hospital guard. Experience is the only guide, but this is a fallacious one. The means of prevention of typhoid fever among troops on the march is almost as far from settlement as ever. Strict hygiene, so far as this can be carried out, and as pure drinking water as possible, will go a long way toward keeping the disease at bay; but when it has once gained a foothold in an army on active service, to check its spread will employ the brains and energy of the best sanitarians of the world.

ARTERIOSCLEROSIS PRÆCOX.

It is becoming more and more apparent that precocious arteriosclerosis has no necessary connection with senile arteriosclerosis. To state that a young subject with this affection is prematurely old is unjustifiable, even as a figure of speech. Many discrepant statements about hardening of the arteries may be due in part to the dualism of this affection. In the presenile form of the latter the heart and kidneys may be intact, and there are, as a rule, no fibroses of the viscera. Presenile arteriosclerosis appears to result especially from a combination of elevated blood pressure and toxinemia, as shown by a study of individual cases. Such an affection may promptly result fatally if the circulation of the extremities is arrested, or if hemorrhagic infarcts occur in vital organs. On the other hand, this type of disease should be amenable to treatment.

At a recent meeting of the Berlin Medical Society (*Münchener medizinische Wochenschrift*, June 20), Klemperer and Benda reported a case of arteriosclerosis præcox in a man aged 30 who was suffering with rectal cancer. The vascular affection was believed to be due to the toxins of the malignant growth. An atheromatous patch developed in the popliteal artery, and the resulting thrombosis led to fatal gangrene. There was no increased pressure component in the case and the heart was normal. Benda cited another case in a boy in whom a cicatricial stricture of the descending aorta resulted in arteriosclerosis above the constriction. A number of cases were cited to show that toxinemia was pathogenic to the arteries without increase in blood pressure. On the other hand, increased blood pressure is able to induce the lesion without toxinemia, as shown by cases in mankind and animals attributable to overexertion alone. Toxins which augment the blood pressure are more dangerous than others; while arteriosclerosis from muscular exertion alone may be due incidentally to fatigue poisons.

The problem involved in this subject is not entirely solved by a division into early or accidental and late or senile arteriosclerosis. Much may depend on the arterial tunic and segment first attacked, as well as the precise nature of the morbid process.

Nature and Treatment of Chorea.

Carey F. Combs of Bristol writes in the *Medical Press and Circular*, June 7, with regard to the nature and treatment of chorea. According to his views chorea is an organic disease implicating the cells of the cortex cerebri, and those of the midbrain and pontomedullary nuclei to a less severe degree. It is due to the action of rheumatic toxins upon these cells. All parts of the cortex suffer equally, and, therefore, the disease should not be regarded as one of motion only. In spite of its extraordinary persistence, due to repetition of active phases, the general tendency is toward recovery. Combs is of the opinion that treatment should consist in the removal of the cause, active rheumatic infection, by rest in bed with administration of salicylates during the active stages; prolonged mental and bodily rest during convalescence; improvement of general health by fresh air, full diet, and tonics; quieting of excessive movement by sedative drugs or packs; and cure of paresis by massage.

Sodium Salts and Body Weight.

As is well known, Javal and Widal showed that the edema of nephritic and cardiac patients could be reduced by withdrawal of sodium chloride from the diet, and increased by increasing the dietetic content of sodium chloride. As the edema increased there was naturally an increase in body weight. While "salt starvation," so called, is rationally indicated in edema, it is also true that the administration of increased quantities of sodium chloride will increase water retention and weight in a healthy subject. To what extent this is due to increased ingestion of water from the augmented thirst does not appear. At the recent session of the German Congress for Internal Medicine Pfeiffer announced that sodium carbonate also causes increased water retention and increased body weight in both the well and ill (*Berliner klinische Wochenschrift*, May 29) while with suspension of the salt the original weight is regained. Other bases like potassium do not affect the weight, nor does HCl. In treating edema, then, it is sodium starvation which is the desideratum and not mere "salt starvation." An explanation of this behavior of sodium in the body is found in the action of the sodium ion upon the taking up of water by the tissues.

News of the Week.

The Cholera Situation.—The first case of cholera in the Borough of Manhattan appeared on July 23, when the patient applied for treatment at Bellevue Hospital. When the nature of the disease was determined he was at once removed to Swinburne Hospital. The man was a fireman on a tramp steamship which sailed from Liverpool on March 15, and, after touching at the Azores and South American ports, entered New York. Since the outbreak of the epidemic there have been ten deaths from the disease on Swinburne Island, and a number of patients are still detained there, all of them having come from Mediterranean ports. The Treasury Department on July 20 issued a formal order to all national, State, and local quarantine officers requiring a bacteriological examination of every steerage passenger arriving at an American port from a cholera-infected port. This will exclude all cholera "carriers." As a further step to increase the efficiency of the New York quarantine Governor Dix has ordered for the present a discontinuance of the fresh water investigation of quarantine affairs which has been in progress for some weeks. The Italian authorities still endeavor to disguise the seriousness of the situation, but advices from Rome state that during the five days ending July 16 there were in the city of Naples 64 new cases and 21 deaths, while in the province of Naples there were 48 cases and 19 deaths, and in Palermo 62 cases and 19 deaths. Several cases have also been reported in small towns in the neighborhood of Montpellier, France; and the Russian newspapers tell of scattered cases throughout the Empire. One fatal case of cholera has been reported in Boston.

Criticism of the New York City Health Department.—The committee for the reduction of infant mortality of the New York Milk Commission has issued a statement criticising the Health Department inspection of milk. An analysis of the Board of Health's records of milk inspection, the statement says, "shows a marked irregularity in the time and character of inspections and a general ineffectiveness of inspection by reason of failure to follow to a conclusion the delinquencies noted. . . . . The whole process of handling loose milk is at best a filthy procedure, and especially under the dirty conditions found in the ordinary milk shops." The committee refrains from placing the responsibility, but says that "the facts remain that proper supervision has not been maintained nor sanitary conditions observed."

Reduction in Infant Mortality.—During the week ending July 22 there were in New York 344 deaths from all causes among children less than one year old, as compared with 523 deaths in the corresponding week of last year. From intestinal disease there were 157 deaths against 323 from the same cause in 1910. So far this year the number of deaths of infants is 716 less than it was at this time in 1910. As there has been a considerable increase in the infant population of the city the decline in the death rate is even more marked.

City Baths.—It is reported that the new municipal bathhouse at Coney Island, New York, will be open to the public on August 1. The building is one of the finest baths in the world, and will have accommodations for over 6,000 persons at one time, or about 35,000 a day. The roof of the building will probably be utilized as a resting place for invalid mothers and children.

Prize Essay on Alcohol.—Dr. L. D. Mason of Brooklyn, vice-president of the American Society for the Study of Alcohol and Other Narcotics, offers a prize of $150 for the best essay on "The Biological and Physiological Relations of Alcohol to Life." The essay must be the result of original research which shall confirm or disprove the present theories of the inherited effects of alcoholic degeneration and indicate how far the defects of parents are transmitted to the children. The essay must be typewritten and sent to Dr. T. D. Crothers, Hartford, Conn., Secretary, before July 1, 1913. This offer is open to students in all countries, and each essay should be accompanied by a motto and a sealed envelope containing the same, with the author's name and address.

Fire in Insane Hospital.—The State Hospital at Morris Plains, N. J., took fire on July 21, fortunately at about noon, so that it was possible to hurry the 1,200 inmates into the dining hall and keep them there until the danger was over. The fire, which at one time threatened to destroy the main building completely, was finally extinguished with only about $8,000 damage done. It was thought that the cupola of the building had probably been struck by lightning during the early morning storm, and that the fire thus kindled had smoldered until noon.

Chinese Medical School.—The establishment of a medical school in China, for the purpose of teaching to the Orientals the Western methods of hygiene and medical treatment, has at length been accomplished, and the institution, which will be situated in Shanghai, will open its doors in February, 1912, under the auspices of the Harvard University Medical School. Dr. Martin R. Edwards will be the head of the new school, and he will have a corps of fifteen assistants, most of them Harvard graduates.

Child Workers.—The National Child Labor Committee has recently opened in New York an exhibit showing by means of photographs, statistics, and graphic illustrations the prevalence of child labor in factories, and the effect of such labor upon the development of the minds and bodies of the children. The committee is endeavoring to effect the passage by the State Legislature of bills prohibiting the employment of such labor.

Dr. G. W. Crile of Cleveland, Ohio, spoke to the physicians of San José, Cal., in the San José high school on July 7 on the subject of "Surgical Shock."

Gifts to Charities.—By the will of the late John Dobson of Philadelphia the sum of $10,000 is bequeathed to the Episcopal Hospital of that city.

The city of Poughkeepsie, N. Y., has received a gift of $50,000 from Mrs. Samuel W. Bowne of New York, to be used for the erection of a tuberculosis hospital to be known as the Samuel W. Bowne Memorial Hospital. The city had already started the erection of a hospital designed to cost $40,000, and the addition of Mrs. Bowne's gift will render it possible to make the institution one of the most complete in the country.

By the will of the late Nathaniel Thayer of Boston the Massachusetts General Hospital of that city receives a bequest of $50,000. The Boston Lying-In Hospital also receives a bequest of $10,000, and the Clinton Hospital one of $5,000.

The Auburn City Hospital of Auburn, N. Y., receives $5,000 under the will of the late Mrs. Eliza Wright Osborne of that city.

Mount Sinai Hospital of New York receives $2,000, the Montefiore Home, $2,000, and the Beth Israel Hospital, $1,000, under the will of the late Alfred Krower of New York.

Lectures on Tuberculosis.—In cooperation with the Committee on the Prevention of Tuberculosis, the New York City Department of Health has begun the fifth season of free stereopticon lectures on the causes and prevention of tuberculosis. The lectures are given in the parks and on the recreation piers during the summer, beginning on July 21.

Mr. Nathan Straus has been appointed a delegate to the third international congress for the protection of infants, to be held in Berlin on September 11 to 15. This body was formed in Paris as the Congress of the Gouttes de Lait, but at the meeting, in Brussels in 1908, the name was changed and the scope of the organization was broadened.

University of Arkansas.—The Faculty of the Medical Department of the University of Arkansas recently elected Dr. J. H. Lenow of Little Rock to the office of Dean of the Consolidated Medical College. Dr. J. P. Runyon was elected Vice-Dean.

Austin Flint Medical Society.—At the annual meeting held in Mason City, Iowa, on July 11 and 12, the following officers were elected for the ensuing year: *President,* Dr. J. C. Power of Hampton; *Vice-President,* Dr. E. E. Denkleburg of Waterloo: *Secretary,* Dr. C. F. Starr of Mason City; *Treasurer,* Dr. W. L. Hearst of Cedar Falls. The next meeting will be held at Waverly.

Loudoun County (Virginia) Medical Society.—At a meeting held in Leesburg on July 14 the Loudoun County Medical Society was formed with the following officers: *President,* Dr. N. G. West of Leesburg; *Vice-Presidents,* Dr. E. H. Heaton and Dr. T. F. Keene.

Rutland County (Vermont) Medical Society.—At the annual meeting held at Lake Bomoseen on July 11 the following officers were elected: *President,* Dr. C. F. Ball of Rutland; *Vice-President,* Dr. H. R. Ryan of Rutland; *Secretary,* Dr. William Stickney of Rutland.

Dr. Charles Nélaton, Vice-President of the French Surgical Society, died at his home in Paris on July 23.

The North Carolina State Medical Society.—At the annual meeting of the association held in Charlotte on June 20 and 21, the following officers were selected for the ensuing year: *President,* Dr. A. A. Hunt of Lenoir; *Vic-presidents,* Dr. J. P. Munroe of Charlotte, Dr. W. P. Horton of North Wilkesboro, and Dr. J. G. Murphy of Wilmington; *Secretary,* Dr. A. A. Stanton of High Point; *Treasurer,* Dr. H. D. Walker of Elizabeth City. Hendersonville was chosen as the place of meeting in 1912.

The North Carolina Public Health Association was organized in Charlottee at the time of the meeting of the State society, with the election of the following officers: *President,* Dr. L. B. McBrayer of Asheville; *Vice-president,* Dr. L. N. Glenn of Gastonia; *Secretary-Treasurer,* Dr. W. S. Rankin.

Chicago Medical Society.—At the annual meeting held on June 20 the following officers were elected: *President,* Dr. Joseph M. Patton; *Secretary,* Dr. George F. Suker.

South Dakota Medical Society.—The annual meeting of this association was held in Pierre on June 15 and 16, the following officers being selected for the coming year: *President,* Dr. W. G. Smith of Sidney; *Vice-presidents,* Dr. C. E. McCauley of Aberdeen, and Dr. F. A. Spofford of Flandreau; *Secretary-Treasurer,* Dr. R. D. Alway, Aberdeen. The next annual meeting will be held in Mitchell.

Southwest Virginia Medical Society.—At the annual meeting in Roanoke on June 20 and 21 the following officers were elected for the ensuing year: *President,* Dr. W. W. Chaffin of Pulaski; *Vice-presidents,* Dr. E. C. Watson of Roanoke, and Dr. W. H. Ribble, Jr., of Wytheville; *Secretary-Treasurer,* Dr. A. B. Greiner of Rural Retreat.

National Association for the Study and Prevention of Tuberculosis.—At the annual meeting of the association held in Denver the election of officers on June 21 resulted as follows: *President,* Dr. M. P. Ravenel of the University of Wisconsin, Madison; *Vice-presidents,* Dr. John M. Glenn of New York, and Dr. G. W. Holden of Denver; *Secretary,* Dr. Henry Barton Jacobs of Baltimore; *Treasurer,* Dr. George M. Sternberg, U. S. A.

American Surgical Association.—The annual meeting of the association was held in Denver on June 20 and 21, the following officers being elected: *President,* Dr. Arpad G. Gerster, professor of clinical surgery in the College of Physicians and Surgeons, New York; *Vice-presidents,* Dr. George W. Crile of Cleveland, and Dr. Joseph Ransohoff of Cincinnati; *Secretary,* Dr. Robert G. LeConte of Philadelphia; *Treasurer,* Dr. Charles A. Powers of Denver; *Recorder,* Dr. Archibald McLaren of St. Paul.

Edgar County (Illinois) Medical Society.—At the annual meeting held in Paris on June 20 the following officers were elected: *President,* Dr. B. G. R. Williams of Paris; *Vice-president,* Dr. J. W. Evinger of Elbridge; *Secretary-Treasurer,* Dr. George H. Hunt of Paris.

Jones County (Ia.) Medical Society.—At the annual meeting at Anamosa, on June 6, the following officers were elected: *President,* Dr. Hejinian; *Vice-President,* Dr. Aileen Corbit; *Secretary-Treasurer,* Dr. Thomas Redmond.

Obituary Notes.—Dr. Henry F. Horstman of Philadelphia, a graduate of the Medical Department of the University of Pennsylvania in 1873, died at his home, on July 6, aged 65 years.

Dr. James E. Keating of Natick, Mass., a graduate of the Harvard University Medical School in 1879, died at his home on July 4.

Dr. W. Thomas Jones of Natchez, Miss., a graduate of the Jefferson Medical College, Philadelphia, in 1904, died of septicemia, on July 8, aged 36 years.

Dr. Michael F. Foley, formerly of Hoboken, N. J., and more recently of New York, a graduate of the Bellevue Hospital Medical College in 1891, a member of the New Jersey State and Hudson County Medical Societies, and formerly visiting surgeon to St. Mary's Hospital, Hoboken, died suddenly at his home in New York, on July 24, aged 43 years.

Dr. Hugh Pitcairn, formerly of Harrisburg, Pa., and for eleven years American Consul-General at Hamburg, Germany, a graduate of the Hahnemann Medical College of Philadelphia in 1880, died at Hamburg, on July 19, aged 66 years.

Dr. George L. Andrew, Chief Inspector on the Sanitary Commission for the Army of the Potomac during the Civil War, a graduate of the Cincinnati Medical College, and house physician at Bellevue Hospital, New York, before the outbreak of the war, died at his home in Laporte, Ind., on July 19, aged 89 years.

Correspondence.

THE PRELIMINARY PLACING OF THE PERINEAL STITCH.

To the Editor of the Medical Record:

Sir:—I have received so many requests from family doctors for the technique of my very simple method of placing the perineal sutures before the lacerations take place that I am unable to answer them all individually, and would therefore crave from you space in your journal for this letter to which I may refer them.

At the Boston meeting of the American Gynecological Society in 1904 I had the honor of presenting a paper on "The Immediate Repair of the Perineum with Special Reference to the Placing of the Sutures in Position Before the Laceration Takes Place." Since then about 1 or 2 per cent. of the doctors of North America have adopted it and another 2 or 3 per cent. want to know more about it. In the paper which will be found in full in the transactions of the Society I pointed out the two great reasons for the immediate repair of every laceration of the perineum; first to close up the avenues of infection which are the cause of the mildest as well as of some of the most severe cases of puerperal fever; and second to reunite the separated levator ani and transversus perinei muscles. During the last twenty years I have made it my invariable custom to put in a stitch or two in every case in which even half an inch of the fourchette had been torn. The result has been that my obstetric cases have been almost entirely free from the slight rise of temperature on the second or third day, formerly called milk fever. I am certain that patients who have had these small lacerations of the perineum repaired have made better convalescence than those on whom this was not done. Moreover, in a part so abundantly supplied with nerves, it is important to obtain repair by primary union rather than by contracting scar tissue, which breaks down the nervous system. Besides, when the sphincter is torn through, the patient loses control of her bowels and must retire from social intercourse. I admit that the difficulties of the immediate repair of the perineum are very great, if done in the ordinary way, and especially with poor assistance and poor light in a poor house, and it would be better to send for an expert in plastic work who, with the help of a nurse and the family doctor, could quickly sew up all tears. But in cases where such a man is not available even the least expert family doctor could not only close up all tears but actually accomplish that most difficult feat of securing the divided and retracted ends of the levator ani muscles, if he will but use the method which I have devised.

Method.—Just before the child's head comes down on the perineum the patient is anesthetized and brought across the edge of the bed with the feet held by a twisted sheet or leg holder. The perineum is sterilized with a soap and brush and mercuric bichloride, and then with the large curved perineum needle on a handle, furnished by Chapman of Montreal, held firmly in the right hand, and with the thumb of the left hand in the anus and the left forefinger in the vagina the needle is entered at the base of the lesser lip on the patient's left, taking in the levator ani muscles and passed rapidly under the vagina and about two and one-half inches above the fourchette, coming out at the corresponding point on the woman's right side. A silkworm gut suture is threaded into it and the needle is withdrawn, followed by the silkworm gut, the two ends of which are caught up with two Péan forceps. A second one is passed in the same way an inch lower down, but taking in the muscles of the perineum. We can generally tell beforehand, by the rigidity of the perineum, whether the tear is going to be a bad one or not. In the former case we can put in a third stitch, which would take in the sphincter ani on each side of the middle line. Delivery can now go on naturally or artificially, but as soon as the placenta has been delivered the perineum is inspected under a good light and a stream of water, all clots being rubbed off with the finger; the stitches are tied from above downward, when we will find that there is absolutely accurate coaptation of the separated parts.

Speaking of the light in the confinement room, especially of the poor, we should always take steps before delivery to provide a good light for two reasons: that we may see how dirty the place is and second to see what we are doing. As a rule, a darkened room means a dirty and badly ventilated one. In the daytime arrange the patient so that the perineum will be facing a bright window; and if the confinement is likely to take place at night provide beforehand for a good light easily available for examining the perineum. When we hear physicians say that they have never seen a tear of the perineum they may be telling the truth, because they have attended all their patients in a dark room. The presence of the silkworm gut stitches, placed as stated before the head comes through the perineum and hanging loosely attached by their ends to a Péan forceps, does not interfere with the termination of the labor in any way, not even when the forceps is required. If by keeping the pain under control and the head well towards the symphysis, there has happily been no laceration of the perineum, no harm is done by their having been introduced, you simply take off the forceps and draw them out, while if the perineum has been lacerated more or less, it is a great advantage to save time by having them already in, but still more by having them exactly in the right place to bring the lacerated surfaces together, just as they were before the delivery. The placing of the perineal sutures before the tear occurs is an instance in which "an ounce of prevention is worth a pound of cure."

A. Lapthorn Smith, M.D.
238 Bishop Street, Montreal.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

THE INSURANCE BILL, MORE OBJECTIONS—HEALTH CONGRESS AND FÊTE—OPEN-AIR SCHOOLS—SURGEON WRENCH, M.V.O.—ROYAL COLLEGE OF SURGEONS—ITEMS—OBITUARY.

London, July 7, 1911.

Dissatisfaction with the details of the Insurance Bill marks its progress. Continually some interest which is affected is representing its apprehensions of injury. The announcement of a determination to apply the guillotine caused such protests from the labor party that the government was glad to climb down. The finance committee of the London County Council objected among other things to be liable for expenses incurred by health committees, and in certain eventualities in respect of excessive sickness, as well as to the powers given to

local authorities in reference to the establishment of sanatoria. It seems that the local health committees are to have the right to draw upon the rates for the expenditure as to medical benefits, subject only to the provision that such expenditure has been reasonable. Is not that a point to furnish lawyers with increase of employment?

A conference of representatives of the dispensaries in London and the provinces has been held at which it was shown that in some towns about a third of the people were in provident or free dispensaries, and it was the general opinion that these institutions would all be injured and many of them destroyed. A resolution was passed that they ought to be utilized under the scheme, as they had existed many years for the benefit of hundreds of thousands of the working classes.

The Council of the Charity Organization Society urges that the measure ought not to be pushed forward until ample time has been given for discussion and that cannot possibly be secured in the present session of Parliament.

In Ireland the scheme is rousing so much opposition, not only of medical but other interests, that a demand is being strongly urged that the bill shall not extend to that island. The Roman Catholic authorities are joining in the opposition of the university and the colleges. The Irish Medical Association has sent a circular to every practitioner in the country asking whether they will refuse to contract under the bill unless its demands are met. Some Irish M.P.'s have promised to seek amendments, but the majority of them vote as Mr. John Redmond dictates, and the government must await his pleasure or he will remove them from office.

A White Paper has been issued giving the text of a number of letters sent by Mr. Lloyd George to correspondents respecting the probable effects of the measure. In one of them he tries to show the bill will benefit the profession, that the payments are not fixed and will probably be raised, and that the free choice of the doctor is not unreasonably restricted, but a man ought not to change every month or two! He thinks cottage hospitals will not be interfered with.

The Imperial Health Congress has been sitting for the last two days. In connection with it the Duke of Argyll, in the absence of Princess Louise from indisposition, opened a fête in the Royal Botanic Gardens, which proved a brilliant success, the weather being all that could be desired. There were all sorts of exhibits, such as the model workroom of the girls' clubs, laces, embroideries, and ladies' work of various nations.

The "Florence Nightingale Caravan" was composed of an underguard of Crimean veterans. The Duke spoke in commendation of the aims and work and then followed musical and dramatic entertainments and interesting displays of the ambulance association and the Women's Sick and Wounded Convoy Corps.

The formal opening of the Congress itself yesterday was presided over by Lord Ilkeston and a paper was read on "Tropical Diseases as They Affect Women and Children," by Dr. C. W. Daniels of our School of Tropical Medicine. A discussion on the "Care of the Teeth" was opened by Dr. Sim Wallace. In the afternoon Sir W. Bennett presided and such subjects as Open-Air Life in Canada, Dancing in Connection with Open-air Life, Morris Dancing, and the Training of Oriental Children were discussed. To-day the Tuberculosis Problem and the Endowment of Maternity in Relation to Eugenics are to be considered, and Dr. Sandwith is to speak on the "Prevention of Plague."

Yesterday an open-air school for tuberculous children was opened by the Duke of Argyll. It was organized by the Kensington and Paddington Dispensary with the cooperation of the London County Council, which has supplied the educational staff, filled up the building, and agreed to maintain it for three years as an experiment. The chairman of the L. C. C. was present and hoped parents would help in promoting hygienic conditions at home. The Duke, in declaring the school open, said he thought it a good thing to occupy the minds of invalid children with their education rather than let them brood on their state and they might be told how many great poets and others had been great sufferers.

Dr. Dudfield hoped the school would be a pattern for many others to be started. He thought, too, open-air schools would be best for healthy children and should not be reserved for the sick.

Surg.-Lt.-Col. Edward Mason Wrench, M.V.O., F.R.C.S., who distinguished himself in the Crimea, is now in good health at the age of 78 and acts as a J. P. for Derbyshire. He was at both assaults on the Redan and served to the end of the war. Afterwards he was sent to India in charge of troops and served throughout the Mutiny. He was awarded medals and clasps and since leaving the army has held various appointments and contributed to the journals—one article being "Lessons of the Crimean War." Mr. and Mrs. Wrench lately celebrated their golden wedding and among their presents was a golden casket from the Duke of Devonshire's mother. He had attended three Dukes. Other presents were from nine brothers and sisters and forty-nine nephews and nieces. King Edward consulted Mr. Wrench and personally decorated him.

The specimens added to the Hunterian Museum during the last twelve months include an important collection illustrating cancer in mice, presented by the Imperial Research Fund. Sir Henry Butlin has given his drawings showing the appearances of this disease and conditions which may be mistaken for it. The tuberculosis commission has given a series of specimens showing the experimental production of that disease. Great additions have also been made to the pathological and gynecological collections. Numerous donations to the ethnolgical series are interesting in various respects. The exhibition closes to-morrow.

Yesterday Mr. Makins and Mr. Dent were reelected to fill the two seats on the Council of the College vacant by their retirement in rotation. Mr. Lyttelton, M. P., distributed the prizes at Guy's Hospital on Tuesday. He commended to the students a remark of the late Dr. Jowett, "Don't quarrel, don't explain, don't drudge." They must be practical as well as scientific to succeed, must keep the human side open or would fail. The garden party, after the ceremony, was as pleasant as usual and as largely attended.

Mr. R. C. Forster, who gave £4,500 to secure the purchase of the site for the new chemical laboratories of University College, has offered a further gift of £30,000 in the hope that the building may be speedily proceeded with and so the coronation year commemorated.

On Wednesday H.R.H. the Duchess of Albany laid the foundation of the new building of the Cen-

tral London Ophthalmic Hospital, which was opened in 1843. Last year 12,000 out and 400 in-patients were attended to.

Dr. Thomas Edwin Burton Brown, I.M.S., C.I.E., has died at the age of 78. He was a Guy's student and took M.D., London, in 1857, having obtained gold medals in several subjects. Most of his life was spent in India, where he became Professor of Medicine and Principal of the Lahore College. He had previously been Examiner in Chemistry to the Punjab government. Returning to England he was appointed medical tutor to Ayerst Hostel, Cambridge, in 1890, and next year Examiner to the Apothecaries' Society, of which he was chosen master in 1901. He was president of the Therapeutical Society in 1906 and vice-president of the Royal Society of Medicine.

Dr. G. B. Slader, M.O.H. for Gainsborough for sixteen years and surgeon to the Dispensary, died on the 22d ult.

Dr. Thomas Law Webb, late pathologist to the Salop Infirmary and the Shrewsbury Throat and Ear Hospital, has died at the age of 64. He qualified in 1870 and took M.D., Birmingham, in 1903.

Dr. Herbert Thompson, many years surgeon to the Hospital for Hip Disease and the Sevenoaks Cottage Hospital, died suddenly on the 20th ult.

OUR LETTER FROM PARIS.

(From Our Regular Correspondent.)

ACADEMY OF MEDICINE—RADIOTHERAPY—SURGICAL SOCIETY—A NEW METHOD OF PROSTATECTOMY—PENETRATING WOUNDS OF THE THORAX—MEDICAL SOCIETY OF THE HOSPITALS—GASTRIC RADIOSCOPY.

PARIS, June 15, 1911.

At the Academy of Medicine Haret has advanced the happy idea of introducing radium into the tissues through the intact skin, under the form of ions, by means of the galvanic current and the electrolytic solution of a salt of radium placed on a positive electrode in contact with the diseased region. Béclère presented the following conclusions as the result of experiments: His radium passes into the subcutaneous tissues by ionization, which is necessary to carry the radium without breaking the skin into the subcutaneous tissues; ionization is sufficient, independent of the circulation of the blood, to carry radium into the depths of the subcutaneous tissues; radium penetrates by ionization in quantities appreciable up to 9 cm. of depth at least. The stay of the radium introduced by ionization into the subcutaneous tissues is sufficiently long to permit the accumulation of doses by successive sittings at intervals of several days, and by this accumulation in sufficient quantity one is able to get therapeutic results. The technique of Dr. Haret is as follows: the application over the diseased area of a positive electrode consisting of a compress soaked in the solution of 10 micrograms of bromide of radium and the passage of a current of 10 milliampères for 30 minutes with three sittings per week. This new method of employment of radium in therapeutics constitutes a true advance. There is a possibility in this way of causing radium to penetrate without any break in the skin to the interior of the cellular elements of the different tissues; one may predict that there will be an advantage in many cases in combining the employment of this new method of radium therapy with that of irradiations of Röntgen rays, and that the domain of both agents will be broadened.

At the Society of Surgery Paul Delbet presented a new method of prostatectomy, perineo-transurethral. According to the author this method includes the advantages of the two other methods usually employed, the subpubic and the perineal, and avoids their inconveniences. The patient being placed upon a table in inverse position, the operator introduces into the urethra a Guyon No. 2 explorer, and makes three incisions; one vertical median, 3 cm. long, following the convexity of the explorer; the two others, 1½ cm. long, start from the beginning of the posterior extremity of the former and surround the half circumference of the anus. After incision of the soft parts the urethra is opened longitudinally, then the membranous and prostatic urethra are divided. The urethra is then dilated by Hegar's bougies to the diameter of about 1 cm. A small tent is then introduced through the dilated urethra as far as the bladder and placed in the neck, which draws it slightly downward. The right index finger is then engaged in the urethra; it tears the mucosa within the limits of the neck of the bladder and urethra, passes into the plane of cleavage, and isolates the prostatic adenoma, which is then extracted in one or more pieces with forceps. The operation is then finished; a large Pezzer sound is put in place. Paul Delbet has operated under these conditions on an old man of 73 years of age; the operation was simple and rapidly done in 15 minutes. For penetrating wounds of the thorax Professor Delorme advocates early operation. He thinks that when there are marked functional signs such as physical signs of much hemorrhage, instead of being absolutely contraindicated, operation should be considered as plainly indicated, safe, and beneficial. In cases in which the symptoms are more grave, agonizing even, there is an indication for hastening surgical action, and by an opening which permits one to see everything to perform the surgical operation necessary under the circumstances. Lejars believes that immediate thoracotomy in certain wounds of the thorax may be an operation of safety. At the same time the formula of indications for operation is far from mathematically established; it is the aggravation of the symptoms after some hours which should determine surgical action. As soon as the first stage of cardiopulmonary shock is past, after the patient is warmed, calmed, and stimulated, if one finds that the pulse becomes weak again, pallor increases, and respiration becomes more and more difficult, direct intervention may cut short threatening symptoms. Rochard thinks that the operation is indicated only when the case is very grave. He believes that operations should be more numerous and there will be more successes. Michaux is disposed to operate in cases of grave hemorrhage and infection, but thinks that these cases are rarer than is generally thought. Demoulin thinks that in penetrating wounds of the thorax it is abundant hemorrhage that should guide the surgeon. One can judge of this abundance according to the quantity of blood which flows from the thoracic wound or from the mouth, or which accumulates within the thorax. When a wounded man bleeds abundantly and his life is in danger one should not hesitate; it is necessary to reach the source of hemorrhage whatever its origin. Souligoux thinks that the unanimous belief of all surgeons is this: in the immense ma-

jority of cases the treatment of choice in wounds of the thorax is immobilization of the patient, whose wound has been previously made aseptic and has been bandaged. But there are circumstances in which the surgeon should interefere by wide thoracotomy and pulmonary suture. Souligoux distinguishes four types: (1) when the hemorrhage is very abundant and the life of the patient is in immediate danger one should not think of operation; (2) when the general condition is serious the surgeon hesitates and asks himself what he ought to do; (3) when the hemorrhage, after remaining stationary, increases slowly and places the life of the patient in danger, one should undertake thoracentesis, and if the blood removed is pure a thoracotomy is necessary; (4) lastly, when the bleeding is not abundant and does not increase, and has no tendency to resorption, one should have recourse to a pleurotomy preceded by a resection of the thoracic wall. Thiery believes that one should operate only in very grave or desperate cases. One should first practise massive intravenous injections of serum, and if the condition of the wounded man still remains alarming one should lose no time and should go straight to the source of hemorrhage. Riche thinks that surgical operation in wounds of the thorax has but rare indications. It is the aggravation of the original conditions or the recurrence of a grave state after a less alarming condition which should arm the surgeon. Operation should not be decided on at a glance: one should not leave the wounded man or should see him at short intervals. Tanton believes that operation in wounds of the thorax should be indicated by physical signs of considerable and very rapid hemorrhage and continued aggravation of the functional symptoms; in particular, progressive weakening of the pulse and increase of dyspnea. Finally, the coexistence of a pneumothorax and the communication of the hemorrhage of the pleura with the exterior should indicate operation.

At the Medical Society of the Hospitals gastric radioscopy was the topic for discussion. The importance of radioscopic exploration for the diagnosis of gastric affections no longer needed demonstration, and Enriquez and Gaston Durand brought before the society an important contribution on the subject. The systematic examination by radioscopy of all subjects of gastric disease had shown the extreme frequency, especially among women, of those radioscopic images in which ptosis was associated with dilatation and atony. It was not the least of the items of progress shown by medical pathology in gastric disease which permitted one by the simple interpretation of a schema to determine not only the organic modifications of the stomach, but also functional disease of the muscular fiber almost at its beginning. One should insist on the facility with which most ptoses of the stomach were relieved by pressure exerted from below upward on the abdominal wall, and Enriquez has recommended a permanent retention of gastric ptoses by means of a pneumatic cushion attached to a belt. This method has given excellent therapeutic results. Gastric radiology rendered daily great services, but one should never forget that that all radioscopic observations had reference solely to a stomach filled with bismuth, and that the clinician might always object that the image, the movements, and evacuation of a bismuth stomach might not be identical with those of a stomach filled with food. One should bring to bear on the results of gastric radiology a certain amount of reserve. Béclère thinks also that the essential factor in the radiological exploration of the stomach was never to be contented with the morphological study of that organ, but always to join with it and associate with it the functional examination.

MEETING OF THE CANADIAN MEDICAL ASSOCIATION IN MONTREAL.

(From Our Canadian Correspondent.)

MONTREAL, July 10, 1911.

IN the Section of Surgery one of the most interesting papers read was that by Drs. J. Halpenny and John A. Gunn of Winnipeg. The subject matter of this paper was a description of the extirpation of the thyroid gland in monkeys. Investigators are not agreed as to the possibility of inducing myxedema in monkeys. Vincent and Jolly, for instance, after careful experiments, concluded that myxedema and cretinism must be due to causes more complex than simple thyroid insufficiency. Horsley, Murray, and Edmunds, on the contrary, declare as the result of experiments that it is possible to induce such conditions in monkeys. The majority of text books, on the authority of these well-known investigators, have taught that myxedema and cretinism are due simply and solely to thyroid insufficiency and that it is possible by removal of the thyroid to reproduce very accurately the clinical pictures furnished by these diseases. Halpenny and Gunn, in order to settle the point, have repeated experiments of simple extirpation of the thyroid in monkeys. All the monkeys used for the purpose of experiment were of *Macacus rhesus* species. The operations were much more serious in the hands of Halpenny and Gunn than in those of Vincent and Jolly. None of the animals operated on was wholly free from symptoms, although such was the case in several of the experiments of Vincent and Jolly. But, on the other hand, none of the animals had the symptoms of myxedema found by Horsley. It was suggested by Halpenny and Gunn that the difference in the species of the monkeys together with the difference of climatic conditions may have contributed to the results arrived at by them differing from those of Horsley and others who have come to the same conclusions as he came to. The entire paper dealing with this matter is is to be published by Drs. Halpenny and Gunn in "The Journal of Physiology," edited by Professor Schäffer.

Francis J. Shepherd, M.D., LL.D., Surgeon to Montreal General Hospital and Dean of the Medical Faculty of McGill University, read a brief paper giving a description of the rare condition of tuberculous osteomyelitis of the symphysis pubis.

Dr. C. E. Preston, Ottawa, reported several cases in which astragalectomy was performed, and from his experience with these formed the following deductions: That the operation is essential in advanced types of deformity of the foot with lateral deviation and that with further procedure and proper position it ensures a stable foot of improved appearance and able to bear the weight of the body.

A notable paper read in the Section of Obstetrics and Gynecology was that by Dr. William Gardner, Professor of Gynecology in the McGill University and Gynecologist to the Royal Victoria Hospital, Montreal. The title of the paper was "Common Mistakes in Gynecological Diagnosis." Dr. Gardner

said in part: "Accuracy in the diagnosis of pelvic conditions depends mainly on education of the sense of touch. This can only be attained by long and patient practice and by much opportunity for making examinations. Fewer mistakes would be made if attention were given to a few simple details. In this as in everything else in medicine, the grand safeguards against mistakes are system and method in case taking and examination. As a rule, a woman's pelvic organs cannot be satisfactorily examined if she lie on a bed or couch. A firm surface is needed as a table. The condition of the adjacent viscera, the bladder, and rectum is all important. With regard to the bladder my own practice, learned by personal experience, is to empty the bladder by catheter after the patient is in position on the table. The advantages of the procedure are: 1. We may note the presence or absence of discharges, such as that of gonorrhea, about the genitals, and their character, a very important kind of evidence which we would lose if we allowed the patient to pass water naturally. 2. There are many women who when asked to pass water immediately before a pelvic examination are unable from nervousness to do so. 3. We get an uncontaminated specimen of urine for examination."

Dr. Gardner warns against the use of the sound in physical examination for pelvic diagnosis. He thinks it a much overrated instrument. He points out that mistakes in the diagnosis of retroversion of the uterus are among the most frequent. Mistakes in overestimating the importance of deviation of the uterine axis from the normal are fairly common. Another mistake not infrequently made is the failure to recognize that in many women a displaced uterus is only one element, although certainly a very important one, in a case of more or less general descent or sagging of abdominal viscera, the condition of enteroptos. The sensations of the patient which suggest to her mind displacement of the uterus and which are apt to be accepted by the inexperienced physician, are often due solely to vaginitis. No more common mistakes are made than in the diagnosos of pregnancy, and this is a fatal mistake for the medical practitioner to make. It is even more difficult in the case of extrauterine pregnancy. Mistakes are made in the diagnosis of cancer of the uterus, and Dr. Gardner draws attention to the fact that the most significant symptom of the early stage of cancer of the uterus, cervix, or body is the appearance of a thin, serous, slightly turbid, sometimes pinkish at first, and for many weeks usually inodorous discharges. Dr. Gardner concluded by mentioning mistakes made which concern and influence the sexual hygiene of women. Girls should be taught sexual hygiene by mothers, and if not by mothers by medical men.

The diversion of those attending the meeting was well looked after. There were garden parties, receptions, and golf matches for those frivolously inclined or who needed relaxation from the sterner duties of the convention. An outing which combined instruction and pleasure was that made by the members of the association on the afternoon of the closing day of the meeting to Macdonald Agricultural College, situated some twenty miles from Montreal. This college, which is incorporated with McGill University, was founded, erected, equipped, and endowed by Sir William C. Macdonald, a prominent citizen of Montreal, whose gifts to McGill University reach a total of about $5,000,000. The objects of Macdonald College are: 1. The advancement of education; the carrying on of research work and investigation and the dissemination of knowledge; all with particular regard to the interests and needs of the population in rural districts. 2. To provide suitable and effective training for teachers and especially for those whose work will directly affect the education in schools in rural districts. The college property comprises nearly 600 acres and numerous magnificent buildings. There are the campus, with lawn, school garden, and recreation fields for students of both sexes. Experimental grounds, with plots for illustration and research in grains, grasses, and flowers. The small culture farm for horticulture and poultry keeping and the live stock and grain farm.

The members of the Association spent a most interesting afternoon inspecting farm dairies, gardens, poultry and buildings, and after partaking of a generous tea, betook themselves to Montreal, greatly impressed and interested by all they had seen. In every respect the meeting of the Canadian Medical Association in Montreal was a great success.

SANITARY MATTERS IN CEYLON.

(From Our Philippine Correspondent.)

June 15, 1911.

It is a pleasant surprise to find that through the persistent efforts of modern sanitation the inhabitants of the Island of Ceylon, in the Indian Ocean, are increasing in numbers, which is in marked contrast to the majority of islands of the Pacific, where the inhabitants are constantly decreasing on account of the diseases which the white man has introduced among them. In the sanitary service administered by the British in Ceylon is probably seen at its best that great nation's dealings with the dark-skinned races.

Colombo is the principal port, as well as the largest city in Ceylon. It has a population of about 140,000, of whom about 4,000 (?) are whites. Colombo is being rapidly transformed into a modern city, and probably shares with Manila the honor of being one of the cleanest in the Orient. The Sanitary Department of the island government is in charge of Sir Allan Perry, who has with him an able corps of European assistants. Hospitals have been established throughout the island. At Colombo a large general hospital is maintained, and also a small hospital of about twenty beds for the study of special cases of tropical disease. The general hospital is now being replaced by a modern two-story structure.

In Colombo the water supply is from a practically uninhabited watershed. The distribution is excellent, the service pipes being found in all parts of the town. Especially noteworthy are the many public hydrants in the poorer districts. Bacteriologically, the water is said to be fair. It contains amœbæ, but these are regarded as of the nonpathogenic variety. Night soil is deposited into pails, which are collected daily and the contents dumped into pits at the outskirts of the city. A modern water carriage sewer system is now under construction and 4,000,000 rupees ($1,333,333) worth of work has already been done.

The city of Colombo has probably better macadamized roadways and streets, and more of them, than any city of similar population anywhere in the world. The method of using asphalt and tar to fill the crevices on a broken-stone roadway is being extensively used, and has proven a satisfactory road

surface for the tropics, where the torrential rains are so destructive to roads built upon principles found satisfactory in the temperate zone. The roads generally throughout Ceylon are excellent. Oil is extensively used to keep down the dust. The railways are government-owned and managed, and the cleanliness of the passenger coaches and their general high state of sanitary maintenance would serve as an excellent example for the majority of the railroads of America.

A small medical school is maintained at Colombo, at which degrees are granted to Singalese. The equipment is fair and the school is probably superior to those of Singapore and Hongkong.

Recently a careful examination was made of many cases that had been diagnosed as pulmonary tuberculosis, and it was found that they were pseudotuberculosis. Cultures made in the laboratory showed the oidium and the absence of the of tubercle bacillus, so that it was possible to demonstrate accurately that the true diagnosis was bronchomycosis. The onset of the disease is almost identical with pulmonary tuberculosis. In a typical case there are an afternoon temperature, night sweats, gradual loss of weight, hacking cough, and frequently hemoptysis. Ascending doses of iodide of potassium to toleration usually produce a cure in from two weeks to several months. *Paragonimus westermani* infection is very rare, being usually found only in new arrivals, especially Japanese. Beriberi is also rare. No reliable data could be secured, but it is generally stated that the local grown rice is not polished and that most of the imported rice comes from Rangoon and is only slightly polished.

A rigid maritime quarantine is maintained against all countries infected with the usual quarantinable diseases. No cholera or plague exists in Ceylon. The effectiveness of the quarantine inspection is well shown by the fact that while Ceylon is only a few days' steaming distance from India, that great reservoir of world scourges, and vessels with cases of cholera and plague frequently arrive, yet so far neither of these diseases has gained a foothold. In this connection it is interesting to note the observations of Prof. Castellani, who states that small outbreaks of ten to thirty cases of a disease resembling cholera frequently occur, in which vibrios are recovered from the stools which are culturally almost identical with the cholera vibrios of Koch. Rigid sanitary measures are at once invoked, and usually no further spread takes place.

In the hospital for the study of special cases of tropical disease there was a case of tinea imbricata, which had been experimentally produced from a culture taken from a case infected in the ordinary way. Another interesting case was one of yaws that had been experimentally caused in a typical tertiary syphilitic. Some of the material from a yaw excresence was injected under the skin of the recipient, much in the same manner as a vaccination against smallpox is done by the hypodermic method. In approximately two months the typical eruption of yaws appeared upon the face and arms. This very positive experimental evidence would seem to settle the controversy which has continued for so many years as to whether or not yaws was a manifestation of syphilis. Dr. Castellani reports that salvarsan (606) has proven very successful in the treatment of yaws, and he is of the opinion that, if anything, it is more of a specific in yaws than in syphilis. He has also tried the drug in leprosy but with negative results.

No great progress has been made in Ceylon as yet in stamping out leprosy. The government is now considering the plan at present in force in the Philippines, of rigid segregation. Nastin has proven a failure in the treatment of leprosy in Ceylon. Chaulmoogra oil is regarded as the best remedy which has been used up to the present.

Some Municipal Hospital Problems. C. A. Drew.
Practical Experience with My "Duodenal Tube." M. Gross.
The Relation of Clean Streets to Tuberculosis. S. H. Stone.
Treatment of Bone Tuberculosis at the Crawford Allen Hospital. R. Hammond.
A Case of Rectal Bilharzia. C. N. Meader.
Clinical Note on Potts' Disease. G. C. Moore.

Municipal Hospital Problems.—C. A. Drew discusses the problem of private rooms for pay patients who do not pay their physicians or surgeons. The rules of the Boston City Hospital permit the visiting and consulting staff to send their own patients to private rooms in the hospital and to charge their usual professional fee providing the hospital bill for board and care has been paid, but do not permit a professional bill to be rendered to patients who apply directly to the hospital for a private room and accept the professional service of such physician or surgeon or assistant surgeon as is on duty at the time. This is essentially the same regulation as is authorized by the rules of Worcester City Hospital.

Duodenal Tube.—M. Gross describes the diagnostic and therapeutic applications of this apparatus.

Clean Streets and Tuberculosis.—S. H. Stone recommends the following methods of street management: The smooth paving and regular cleaning of all streets, not by dry sweeping, but by flushing, or, if this is not possible, by sprinkling before sweeping. Exactly what can be done in winter, when flushing or sprinkling is not feasible, is a problem not yet fully worked out. A minimum height of buildings and a maximum width of streets wherever possible, in order that those unequaled germ-destroyers, the sun's rays and fresh air, may have a chance to do their excellent work. The immediate removal of all rubbish and garbage with the consequent lessening of danger from flies.

Bone Tuberculosis.—R. Hammond states that in addition to the outdoor life and the good food he would emphasize sea bathing, carried out systematically, as an important factor in the treatment of these cases. It is a most valuable tonic, and, as the children improve in health, apparatus can be dispensed with at an earlier date than was formerly supposed.

Rectal Bilharzia.—C. N. Meader reports a case from which the practical lesson to be learned is the great importance of a microscopical examination in all cases of recurring diarrhea or bloody stools occurring in patients who have been in the East or in the tropics, since not uncommonly the diagnosis may be established in this way where the true condition would otherwise remain quite unsuspected.

Potts' Disease.—G. C. Moore reports a case illustrating the value of unchanging fixation and the durability and effectiveness of a well cared for plaster of Paris jacket.

On the Determination of the Cause of Death and Some Cases of Sudden Death. H. Oertel.
Health Department Control of Venereal Diseases. P. A. Morrow.
Automatism in Insanity. T. H. Kellogg.
Salvarsan ("606") in Syphilis; a Criticism. C. F. Marshall.
A Warning Concerning the Use of Salvarsan. W. C. Slusher and E. B. Burchell.
The Relation of Uterine Fibromyoma to Thyroid Enlargement. J. R. Eastman and H. K. Bonn.

Report of a Bilharziosis Case in Panama. W. Baetz.
Some Medical Notes Taken in Frankfort-on-the-Main. D. W. Montgomery.

Determination of Causes of Death.—H. Oertel states that one should emphasize the necessity of scientifically accurate clinical records for the proper understanding of anatomical findings. No greater mistake can be made than to expect a pathological anatomist to arrive at correct conclusions without full knowledge of the clinical history. It is sometimes thought by those not well informed that the objective anatomical evidence ought to be separated and not biased by the largely subjective clinical data. But it is forgotten that one is not dealing with mathematical problems, but with a mass of evidence that must be grouped not only in what appears to the investigator as essential and unessential, and in logical sequence, but, much like the work of an artist, plastically reconstructed.

Control of Venereal Diseases.—P. A. Morrow states that the department of public health has a legal right to control cases of venereal disease. The most valuable prophylactic is education of the public. The health board should secure a census of venereal morbidity.

Automatism in Insanity.—T. H. Kellogg discusses the rationale of automatism in the different forms of insanity.

Salvarsan.—C. F. Marshall believes that there are few indications for the use of this drug and that its dangers and inconveniences outweigh its benefits.

Warning Concerning Salvarsan.—W. C. Slusher and E. B. Burchell state that the necrosis and infection following the use of salvarsan are the result of carelessness or disregard of asepsis.

Fibromyoma and Thyroid.—J. R. Eastman and H. K. Bonn report a case in which the amelioration of the thyroid enlargement and general symptom-complex, following the operation for the removal of the uterine fibromyoma, indicates that in this one case at least, the fibromyoma had an obscure causal or other relationship with the thyroid enlargement and its symptoms, the removal of the uterus serving a marked general as well as local therapeutic end.

Bilharziosis.—W. Baetz reports a case of dysentery caused by the bilharzia occurring in the Canal Zone.

Frankfort-on-the-Main.—D. W. Montgomery describes his visit to this city and chiefly his impressions of Professor Ehrlich and his work.

The Use and Abuse of Digitalis in Disease of the Heart. R. Abrahams.
Pregnant Double Uterus. A. E. Acher.
A Case of Cerebrospinal Meningitis. C. C. Snyder and W. R. Tyndale.

Acute Renal Infections.—G. E. Brewer. See MEDICAL RECORD, July 8, page 99.

Extraction of Lens.—V. H. Hulen describes his method of cataract-extraction by vacuum fixation and extraction of the lens in its capsule.

Angiokeratoma of the Scrotum.—R. L. Sutton states that the evidence is almost conclusive that these little vascular tumors of angiokeratoma are simply the result of increased blood-pressure in the superficial venous capillaries, lacking elasticity, as is generally the case in the scrotum. They are nature's attempt to prevent further dilatation.

Intraocular Neoplasms.—F. P. Lewis states that malignant intraocular growths in children are, as is not the case elsewhere, in their beginnings encapsulated. If they are discovered early enough, therefore, life may be saved by enucleation, but if not discovered until the orbital or extraorbital tissues have become involved a horrible death may be expected.

Traumatic Cataract.—J. A. Donovan advises in case of a traumatic cataract, if the patient is seen immediately or soon after the injury, after recovery from the shock and before the local reaction has made careful work almost impossible, that the lens should be extracted. This can be done under local anesthesia, though a general anesthetic is preferable in many cases. If local reaction is already marked one should wait from four to six days, when it subsides, and then remove the lens before the secondary inflammatory symptoms have become severe. A general anesthetic is then necessary. Breaking up the lens and washing it out may succeed, but extraction, he thinks, is in many cases better.

A Serum for Rocky Mountain Spotted Fever.—P. C. Heinemann and J. J. Moore confirm the results obtained by Ricketts and Gomez, who had shown that the horse is susceptible to inoculation with spotted fever virus and that after recovery its serum has protective properties.

Summer Diarrhea.—A. F. Hess discusses the well-known measures to be taken in the prophylaxis and treatment of this condition.

Dyschromatopsia in Brain Tumor.—H. Cushing and G. J. Heuer state that out of the 123 cases in their tumor series, in which perimetric observations could be made, fifty-three showed simple color-interlacing or inversion with more or less constriction of the field boundaries. In ten of the fifty-three cases the dyschromatopsia either actually preceded any recognizable ophthalmoscopic change in the eye-grounds or accompanied the most incipient stages of choked disk. These distortions of the color boundaries, therefore, promise to be of some service in the making of a more precocious diagnosis of an increase of intracranial tension than is commonly ventured on. Thus, in a number of cases of early tumor extirpation, color inversion and interlacing, in addition to attacks of Jacksonian epilepsy, were the only indications of the lesion.

Pulmonary Tuberculosis.—W. Porter recommends in pulmonary tuberculosis the use of cacodylate of sodium and the inhalation of iodine evaporated in a water bath.

Silver Wire for Drainage.—R. M. Harbin recommends the use of wicks of fine silver wire for abdominal drainage after operations for acute appendicitis.

Digitalis in Heart Disease.—R. Abrahams discusses the indications and contraindications for the use of this drug.

Pregnant Double Uterus.—A. E. Acher reports a case of this anomaly.

Cerebrospinal Meningitis.—C. C. Snyder and W. R. Tyndale report a case of epidemic meningitis successfully treated with the aid of the specific serum.

A Clinical Study of Cardiovascular Degeneration. J. M. Bruce.
Outlines of Medical Hydrology. R. F. Fox.
Resection of the Posterior Nerve Roots of Spinal Cord. Professor Forster.
On the Division of the Posterior Spinal Nerve Roots: (I) for Pain; (II) for Visceral Crises; (III) for Spasm. E. W. Hey-Groves.
Note on Three Cases of Fibroid Tumor of the Uterus Spontaneously Fatal. A. H. N. Lewers.
The Therapeutic Effects of Carbon Dioxide Snow. Methods of Collecting and Applying It. J. Hall-Edwards.
Three Cases of Tooth-Plate Impacted in the Esophagus and Pharynx; with Special Reference to the Operation of Esophagotomy. L. E. C. Norbury.

Mice Immunized Subcutaneously Are Resistant to the Implantation of Cancer in Internal Organs. W. H. Woglom.

Cardiovascular Degeneration.—J. Mitchell Bruce states that in some individuals the materials of the cardiac and arterial tissues are of inferior quality; these are instances of inherited dystrophies, producing in part the so-called "family heart." But in the larger proportion of cases the degeneration of the cardiovascular tissues is the result of the action of extrinsic causes—lead, alcohol, the products of bacterial activity, and bacteria themselves; the products and other consequences of disordered metabolism and syphilitic and other parasites.

Medical Hydrology.—R. Fortescue Fox notes that, while modern hydrotherapy has taken a prominent place in the medical practice of nearly every civilized country, in England it is still comparatively unknown.

Resection of Posterior Spinal Nerve Roots.—Professor Forster states that the gastric and intestinal crises in tabes are caused by an irritation of the sensory sympathetic fibers of these organs which enter the spinal cord through certain posterior thoracic roots. Supposing this view to be correct, the crises would cease after the resection of these roots. The operation has now been performed altogether 25 times. In 20 cases the operation was successful.

Division of the Posterior Spinal Nerve Roots.—E. W. Hey-Groves states that for the relief of pain this operation is a somewhat uncertain procedure. For the relief of visceral crises it holds out the only prospect of radical cure. In cases of spasm associated with lesions of the pyramidal tract the operation has the largest field of usefulness.

Death from Fibroids of the Uterus.—A. H. N. Lewers reports three cases as follows: A case of fibroid spontaneously fatal from hemorrhage; a case of fibroid spontaneously fatal from pulmonary embolism, and a case of large interstitial fibroid of the uterus, with sudden collapse, heart failure, and death.

Carbon Dioxide Snow.—J. Hall-Edwards describes the apparatus for preparing and the technique of using this substance.

Tooth-Plate in Pharynx and Esophagus.—L. E. C. Norbury states that in adults the commonest form of foreign body to become impacted in the esophagus is a tooth-plate, and since such plates are often irregular in outline, possessing sharp hooks in many cases, for successful removal esophagotomy is usually indicated. These tooth-plates are generally swallowed during sleep or while the patient is having a fit. Before deciding to open the esophagus in such a case some indication as to the shape and size of the plate may be obtained by interrogating the patient. External palpation may disclose its presence, a view of it may be possible by direct esophagoscopy, or esohageal forceps may detect it. Further, the position, size, and shape of the tooth-plate may be ascertained by means of a skiagram. It may be possible to remove small tooth-plates which do not possess sharp hooks through the mouth with the aid of an esophagoscope, either *in toto* or, if necessary, after division with some suitable instrument. If such attempts fail, however, esophagotomy should be promptly undertaken.

Cancer Immunization.—W. H. Woglom concludes from his experiments that the immune state is one of general distribution throughout the organism and not of local occurrence at the site of the immunizing inoculation, without wishing, however, to have this conclusion applied to the zonal immunity described by Sticker.

July 8, 1911.

The Necessary Influence of the Medical Profession in the Home, the School, and the State. C. Dukes.
The Mechanical Control of Pneumothorax During Operations on the Chest, with a Description of a New Apparatus. H. M. Davies.
A Note Concerning the Treatment of Tuberculosis by "Radioactive Iodine and Menthol." L. Robinson.
On Cesarean Section; with Notes of Ten Cases. C. E. Purslow.
On the Treatment of the Excessive Vomiting of Pregnancy. J. H. Martin.
The Treatment of Aortic Aneurysms. A. Abrams.
Hypertrophied Papillæ of Morgagni Causing Rectal Symptoms. A. C. Magarey.

The Influence of the Medical Profession in the Home, School, and State.—C. Dukes believes that the aim of paramount necessity in the efficient rearing of the young for their life work is the sagacious application of the principles of hygiene to school lift. This can only be accomplished when the teacher is as adequately and specially equipped for his service as the soldier, the sailor, the lawyer, and the doctor.

Pneumothorax.—H. M. Davies describes a new apparatus for the mechanical control of this condition during operations on the thorax.

Radioactive Iodine and Menthol.—L. Robinson describes the results obtained by Szendeffy, Kertez-Aba, and Bernheim in the treatment of pulmonary tuberculosis by means of this substance. It is claimed that this new drug, which is said to act by virtue of the volatility of radium and its elimination by the lungs, acts as follows: it destroys the tubercle bacillus; it has a powerful action on streptococci, and it improves the general condition of the patient by increasing vigor and weight. The drug is given in doses of 1 c.c. by intramuscular injection in the gluteal region.

Cesarean Section.—C. E. Purslow presents brief notes of ten cases of this operation.

Hyperemesis Gravidarum.—J. H. Martin recommends the following as the important point in the prophylaxis and treatment: Relax the bowels at least once a day; prevent oral sepsis; good, plain, well-cooked food is to be daintily served at regular hours; kidneys and skin should be kept active; the patient should take gentle exercise in the open air daily if weather is at all suitable. When hyperemesis gravidarum has developed the following measures are to be employed: Wash out the stomach; keep the bowels, kidneys, and skin active; give nutriment at regular hours, and fresh air night and day.

Aortic Aneurysm.—A. Abrams states that by percussion of the seventh cervical spine one can cause contraction of the normal aorta, and this may act as a symptomatic cure of aortic aneurysm.

Hypertrophied Papillæ of Morgagni.—A. C. Magarey discusses the influence of these in the production of irritation, pain, and the sensation of mass in the rectum, and describes the treatment by means of cauterization.

Berliner klinische Wochenschrift.

July 3, 1911.

Indications for the Vaccine Treatment of Disease.—According to Reiter vaccine therapy should never be resorted to in general infections. The best results are obtained in localized suppurations of all kinds and local tuberculosis and local infections in general. An autogenous vaccine gives the best results. In a localized *Bacillus coli* infection an autogenous vaccine is absolutely indicated. If the case is urgent, or if an autovaccine cannot be prepared, a polyvalent vaccine should be used. One should begin with small doses, seeking to avoid a reaction *in situ* at the outset. When a slight reaction does appear the dose should be cautiously increased. The dose should be so measured that the negative phase should not last over 24 hours. If it last longer the dose was too large. At least five days should elapse between injections.

Escape of a Sacral Teratoma Through the Rectum.—Honigmann reports a case of this sort and finds but one similar case in literature. His patient was a woman aged 43. There was no history pointing to a tumor, and the patient sought the clinic for rectal tenesmus. Even with

the finger and proctoscope no evidence was obtained which pointed to a tumor or other serious condition. The diagnosis was proctitis. Finally a body was expelled which before its passage was believed to be impacted feces, but to the woman's great terror resembled an animal. The rectum gave no further trouble. The mass expelled was small to have caused as much disturbance—only 2.3 cm. in length. It was kidney-shaped and covered with what seemed to be integument in which abundant hairs were present of 1 cm. in length; while at one pole of the mass the hairs formed a long tuft 14 cm. in length and felted. The integument also contained abundant sebaceous and sweat glands. The tumor proper showed a cavernous structure, and there were no other teratological tissues. The growth was therefore a dermoid. The duplicate case mentioned occurred in von Bergmann's practice. The tumor was not expelled but required extirpation per rectum. During straining efforts the tuft of hair used to appear at the anus. This tumor was also a dermoid. Danzel reported a case resembling the two preceding in some respects, but it did not originate like a sacral tumor, being in front of the rectum. It contained bone and other embryonal structures. The patient died of peritonitis following extirpation of the mass. The literature of sacral teratomata is very large, so that failure to report cases cannot be held responsible for the very small number of interrectal tumors in literature.

Blood Finds in Röntgenologists.—Von Jazic and two others representing Prof. Van Noorden have studied the blood of ten men who have used *x*-rays continuously for years. No less than three cases are on record in which röntgenologists have died of lymphatic leukemia, and this can hardly be accounted for by coincidence. There is also a similar case of a chemist who worked with radium. The blood counts do not reveal anything startling, but the average leucocyte count is somewhat lower than normal. The number of lymphocytes is considerably above the average, while that of the polymorphous neutrophiles is correspondingly lower. Most striking of all the changes is the small number of acidophiles, which were totally wanting in several cases. Erythrocytes and large mononuclear leucocytes showed no typical changes. The relationship of the blood picture to that of lymphatic leukemia is of course obscure.

Münchener medizinische Wochenschrift.

June 27 and July 4, 1911.

Pancreas Therapy of Diabetes.—Lesche, who has already published one study of this subject, sums up his work to date as follows: Fresh pancreas extract, which increases the excretion of sugar in diabetic men and animals, has also a glycosuric and toxic—indeed lethal—action on normal animals. Unactivated pancreas extract does not exert this action, while partly activated extract shows a weakened action. Hence there can be no experimental foundation for such a plan of therapy. Not only does an active pancreas extract increase the glycosuria, but it causes abscesses and disturbance of the general health. Even when given by the mouth it increases the glycosuria. The theory of an internal pancreas secretion presiding over sugar metabolism has never been substantiated. The entire pancreas may be destroyed without causing diabetes and conversely the latter may exist side by side with a fully intact pancreas. The real source of the essential factor in sugar metabolism should be the nerve centers.

Puncture Glycosuria.—Von Brücke recalls that Blum, who discovered adrenalin glycosuria in 1902, called attention to the resemblance between the latter and puncture glycosuria so called. It was next learned that after extirpation of the suprarenal bodies puncture in the floor of the fourth ventricle no longer caused glycosuria. Then it was asserted that after the puncture of intact animals the blood serum contained adrenalin as shown by the sensitive frog's iris test; but when the tests were repeated with the utmost precautions negative results came in evidence and it became necessary to study the entire phenomenon of puncture anew. The author found that hyperadrenalemia is not a constant symptom after the sugar puncture, but that it does develop in a good sized proportion of cases. Whether the negative results are due to defective laboratory technique or whether there is an individual or group equation connected with the rabbits tested must be determined by future study.

Pharmacological Justification for an Intravenous Adrenalin Therapy.—According to Straub we are approaching a solution of this problem. We know that adrenalin exerts an action on the pupil, the blood-pressure, the sugar metabolism, the intestinal and uterine activity, the cardiac activity, etc., etc. It therefore becomes difficult to confine its action to one or more organs. As a rule the less the collateral activity in proportion to the specific or main activity the greater the utilizability in therapy. Since adrenalin causes vasoconstriction and at the same time stimulates the cardiac accelerator nerves it appears to have a main action on the blood-pressure. But, in addition to its collateral effects, adrenalin, like all alkaloids, tends to produce a cumulative action. When given intravenously, however, we obtain a transitory action, manifested chiefly in a principal direction. Repetition of injections does not appear to favor cumulation, for the action depends much less on the quantity injected than on the concentration of solution used. It has been found that with a certain concentration adrenalin may be almost continuously infused into the veins, with the production of a steady elevation of blood-pressure which does not exhaust the susceptibility of the organism. Given this concentration the adrenalin is somehow rapidly destroyed in the body. Hence the drug may be indicated in permanently low blood-pressure.

Phosphaturia.—Schlagintwelt writes at great length on this subject, and as he conducts a sanatorium for urinary diseases his facilities for such a line of research are unusual. Since more lime is eliminated than phosphoric acid, he prefers the term calcariuria to phosphaturia. Again, the latter condition must be associated with carbonaturia, since it represents in reality elimination of the excess of alkaline earthy salts from the body, and these salts occur both as phosphates and carbonates. phosphaturia can be correctly estimated only at body warmth: that is, in urine freshly voided. Every hour it stands means increasing bacterial alteration of the urine. Quantitative analyses made minutely and at the analyst's leisure are sources of error. One needs only a Bunsen flame, acid, litmus, and the microscope to appreciate the type of phosphaturia. Of these types the author enumerates no less than five. In Type I the urine is voided clear, clouds on boiling, clears with acids. Its reaction when voided may be neutral, or weakly acid or alkaline. We find it late in the day in the healthy who eat freely of proteid, but we also find it in brain workers, neurasthenics, and the insane. This type also represents a degree of mild phosphaturia. In Type II there are more phosphates, the urine is alkaline, and the phosphates and carbonates fall of themselves when they leave the urinary passages. The urine is milky and becomes more so on boiling. Acid clears it. This type of phosphaturia is known as the manifest, because it occurs spontaneously, while Type I, which is evident only after boiling, is known as latent phosphaturia. Type III represents a higher degree, the phosphates being present as a crystalline sediment. The fourth type is that which occurs in inflammatory affections of the urinary passages, the

crystals being mixed with mucus. The fifth type represents the urine of phosphatic calculus. These clinical types naturally throw no light whatever on the intimate nature of phosphaturia. Given an alkaline urine, as from bacterial action, phosphatic precipitation is inevitable. There should be an essential phosphaturia which is independent of the mere accidental reaction of the urine, and which further is independent of the diet, since alkalinity of the urine is conditioned by the diet. The author here states in advance of proofs that essential phosphaturia is in reality a renal neurosis. Given a general neurasthenic state, then the kidney condition is expressed as phosphaturia. A functionally weakened kidney excretes a urine richer than normal in phosphates. The author devotes several thousand words to expanding this idea. Phosphaturia may have a most innocent or a most malignant significance.

The Wheat Flour Treatment of Diabetes.—Blum compares this with the oatmeal diet and similar dietetic plans. These cannot be employed in routine fashion, nor can they be left to the discretion of the patient. The wheat flour diet is naturally very practical because readily carried out. Many dishes may be prepared from it—bread, toast, rolls, pancakes, macaroni, pastry, and what not. Oatmeal can be served up in but few forms. Recent experience with 35 cases of diabetes has taught the writer that wheat flour diet is superior to all other plans for reducing the quantity of sugar in the urine. It is simple, rapid, and safe. In using it we must not go by a fixed schedule, but modify it according to the exigencies of the individual case. The best results are seen in medium and severe cases in which acidosis is threatened. It is best to reserve the diet for cases which can be controlled perfectly all the time, but this holds good for all dietetic plans.

Bone Cysts.—Brade reports in detail three cases of bone cysts. In one (Case III) the formation could be traced to an osteomyelitis, but the origin of the others was obscure. One could exclude parasites (echinococci, cysticerci), arthritis deformans, Barlow's disease, and callus as causes. For one of the obscure cases (Case II) it may be assumed that it resulted originally from softening of a neoplasm, probably an inflammatory neoplasm. The other case (Case I) could not be thus accounted for, and, reasoning from analogy only, the most plausible supposition is that it originated from an ostitis fibrosa, for this is the most common antecedent of bone cysts. Clinically Case I was a cyst of the trochanteric region of the femur, which made a cripple of the patient. Two years ago he had sustained a injury, from a fall, in the opposite thigh. There was no further history save that the trochanteric region in the supposed uninjured leg began to be painful and the muscles to atrophy. In the second patient the upper epiphysis of the right tibia was the seat of a cyst. There was no history of trauma. Most of the symptoms were referred to the knee joint which was swollen, tender, and partly immobilized. The patient was a cachectic woman. There was a suspicion of tuberculosis. The patient withdrew from observation. The third patient had osteomyelitis, which affected several parts of the skeleton. The cyst formation occurred only in the lower part of one tibia. The *x*-ray is, of course, an ideal diagnostic resource.

Deutsche medizinische Wochenscrift.

July 6, 1911.

Function of the Spleen.—Asher holds that the spleen is an organ for iron metabolism, since it retains the iron which becomes set free by tissue changes for further use. This function has been descovered through animal experiment and confirmed in the case of mankind. Through it we comprehend the nature of leucemia, Banti's disease, and other pathological processes. When the spleen is removed from animals a diminution of the number of erythrocytes occurs with certainty, provided the ingesta are poor in iron.

Enuresis Nocturna and Spina Bifida Occulta.—Peritz describes the so-called occult spina bifida, otherwise known as myelodysplasia, and the clinical picture which accompanies it. The latter is not very clean cut, comprising various congenital anomalies in the sacral region and lower extremities with enuresis nocturna and certain paresthesias. When confronted with enuresis of protracted type which cannot be classed as functional we should suspect the presence of myelodysplasia. The author's personal material of enuresis has consisted of adults, soldiers, and others. In 63 per cent. these patients show congenital anomalies in the sacrococcygeal region, including hypertrichosis, lipomata, fistula-like depressions, various asymmetrics. The feet are often affected (syndactylism, flat foot, pes cavus) but naturally not in the soldiers studied. Thermoanalygesia has been noted. However, occult spina bifida can readily be demonstrated by röntgenography. Enuresis of obstinate type doubtless occurs in degenerate stock in which there is no osseous lesion, so that it is difficult or impossible to show that in any given case the spina bifida is the efficient cause of the enuresis; but there can be no doubt that the two are very often associated. Such cases are not amenable to ordinary drug therapeutics, psychotheraphy, or education. Heubner recommends mechanical measures (extension) to antagonize a supposed pressure on the cauda equina. Cathelin injects up to an ounce of saline infusion into the cauda equina, which has the same effect. A plastic operation should naturally effect a radical cure.

Causal Therapy of Glycosuria and Diabetes.—Funck states that the disturbance of carbohydrate metabolism is not a single process, but comprises at least two types, viz., disturbance of immobilization and disturbance of oxidation. Among the causal elements of diabetes should be mentioned gastric and intestinal affections, which are sometimes obscure in character. By treating these affections first the patient may improve or permanently recover, as shown by acquired and maintained carbohydrate tolerance. Cases are cited in which treatment directed to these affections (gastritis, diarrhea, constipation, etc., etc.) caused a disappearance of sugar in the urine. The diabetic regimen was strictly observed.

Study of Simultaneous Bilateral Tubal Pregnancies.—Paul Launay and Seguinot have observed a case of bilateral tubal pregnancy in which one tube contained twins, three fetuses of the same age being found at operation. This is the only undoubted case of this condition published up to date. There are found in the literature fourteen cases of bilateral tubal pregnancy, but none with twins. The histories of these fifteen cases are given. For the existence of such a condition one must have lesions of both tubes so as to prevent the passage of the ovum through the tube, at the same time that the mucous membrane of the tube is capable of lodging a normal ovum. Impregnation must occur in two ova at the same time and one of them must have a double germ. The diagnosis of this condition has never been made until operation was undertaken. In the author's case the diagnosis was appendicitis. Mere recurrence of pregnancy, with fetuses that were not alive at the same time is not included in this category. Most of the patients were primiparæ and had bilateral tubal inflammations. The author's case was a nullipara without any inflammatory pelvic condition and in perfect health. One tube ruptured three weeks before the other, giving rise to the diagnosis of recurrent appendicitis. The only possible treatment of this condition is removal of both tubes.—*Revue de Chirurgie.*

Insurance Medicine.

SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

THE TIME AND PLACE OF EXAMINATION.

The time and place of examination may be discussed from two points as viewed separately by the agent and the examiner.

The agent considers the convenience of the applicant in making the appointment for the examination. If, in his anxiety to close the deal, he may occasionally go so far in trying to please his applicant as to make arrangements prejudicial to the interests of the company, he should not be criticised too severely, for even after he has induced his applicant to sign the application after some very hard work, he understands only too well that the latter may experience a change of heart at any minute through misgivings and lack of conviction, or he may be persuaded by friends to seek insurance elsewhere, or yield to a tempting offer from a rival agent before the transaction is consummated by the payment of the premium. It is therefore most important to him that the arrangement decided on be promptly and efficiently carried out by the examiner or, if any change is thought advisable, that he be notified by the examiner at once. In the event of failure to finally place the policy, the agent is naturally apt to blame the examiner if, perchance, the latter has not strictly observed all details of the appointment, especially in regard to the time agreed upon.

The examiner naturally prefers that the applicant be brought to his office, not solely to make his own work easier, but rather because the conditions there are more favorable for a thorough examination than those found at the residence or place of business of the applicant. It is a good idea for the examiner to suggest this to the agent, and the latter will usually cheerfully agree to do so whenever the circumstances permit. If, however, the agent finds he cannot meet this wish through the unwillingness of the applicant or because he has such a slight hold on him that he does not dare take any chances, the examiner will assist him and facilitate his work by attending promptly to whatever appointment is made.

Promptness is most highly appreciated by both the agent and the company, as a certain amount of business is lost through delays from different causes, the amount being so large, in fact, that the examiner cannot be advised too strongly against failing to meet the applicant exactly at the time arranged for, even if a change as to place has been made in accordance with the exceptions referred to later on.

Occasionally, especially in small places where all are more or less acquainted with each other, the examiner will be on friendly enough terms with the applicant to venture on tactfully suggesting that the necessary requirements can be fulfilled more comfortably and satisfactorily at his office, in case it has been arranged to have the examination at the applicant's residence or place of business. The companies prefer to have examinations made at the examiner's office whenever possible, having in mind the greater privacy, absence of noise, and the creation of a more confidential frame of mind in the applicant. The examiner, however, should never attempt to transfer the field of operation to his office unless he is quite sure of his ground, as the changing of the plans of the agent is a delicate matter. We would particularly advise the examiner not to request the applicant to call at his office and then wait for him to come regardless of the time already set for the engagement, as such a course is almost sure to lead to friction with the agent. If for some good reason the examiner believes that another place should be chosen or if he finds himself unable to keep the appointment, he would better notify the agent to change the arrangement to a more acceptable one rather than to assume the responsibility himself. Furthermore, if the examiner knows that he cannot carry out the plan adopted by the agent, it will lead to a happier relation between them if the former explains this when the application is presented.

It is the earnest wish of the medical directors, generally, to have all examinations made under conditions which are favorable to precise and complete findings. If, then, an examiner learns that the examination is to be made with so much noise and bustle about that it will amount to nothing more than a farce, his action will be upheld if he insists on the selection of a suitable place, free from noise and intrusion. In addition to quiet there should be privacy, and if this is not possible at the appointed place, the examiner should not hesitate to request some other arrangement. He will usually, however, by the exercise of a little tact, succeed in securing the desired privacy at the appointed place. The privacy should be complete, and this means the exclusion of any third person, no matter how closely related, and also the agent. In the event of the applicant being a woman, the husband or a woman friend may be present during the physical examination, but this should never be permitted while asking the questions on the application blank. The examiner will readily understand the importance of privacy in the examinations, as he is aware that some of his questions will be of such a personal nature that they may not be frankly answered in the presence of a third person. He knows still further that he will need the help of privacy to gain the complete confidence of the applicant before he can elicit certain kinds of information which applicants are prone to conceal.

Operations for the Relief of Gallstones and Their Importance in Medical Selection.—Homer Gage says that in the report of the Massachusetts General Hospital, in the list of major surgical operations performed during the year 1909, operations upon the appendix occupy first place, those upon the uterus and its appendages second, closely followed by those upon the gall-bladder and bile ducts. At the Boston City Hospital and the Roosevelt and Presbyterian hospitals in New York a similar proportion obtained. Dr. W. J. Mayo stated that in St. Mary's Hospital, Rochester, Minn., the relative proportion of operations was: appendix, 345; gall-bladder, 143; ovaries and tubes, 98; stomach, 77. In view of these figures it is important to find out something about the effect of these operations on the future life and health of the individual who has undergone them. Statistical evidence from an insurance standpoint is lacking. From this point of view the effect on the patient's probable expectation of life is more important than the immediate effect of the operation.

The most favored theory to account for the formation of gallstones is the histological or mucous-membrane hypothesis, which conceives the cholesterin and calcium of the bile to be formed entirely by the mucous membrane of the gall-bladder and bile ducts, a catarrhal inflammation increasing their production. Cholelithiasis is really the consequence

of bacterial infection and does not belong to the group of diseases of degeneration. In its inception it is a purely local infection and in its progress represents a pathological condition due to mechanical causes. If unrelieved naturally or by operation it will culminate in permanent impairment of neighboring structures or in acute destructive inflammation of the gall-bladder.

If this theory of the formation of gallstones be accepted, and it is universal, then it is fair to assume that if by surgical intervention the infection and its products are removed before the secondary changes such as cholangitis, chronic pancreatitis, and cancer has developed, a permanent restoration to health moy be accomplished. The only risn of a reformoation is when fragments have been left at the time of the operation or suture or iigament material has betn left in the gall-bladder and remains unabsorobed.

As to effect on the health of the individual who has undergone an operation for gallstones, Kehr provides figures which seem to show that between 70 and 75 per cent. of all cases may be fairly considered cured. Mayo Robson and the Mayo brothers supply equally satisfactory statistics. These, of course, are statistics representing the results of the most expert operators. Homer Gage's results representing the average are not so favorable as those of the operators referred to above, but still satisfactory, and he quotes and agrees with Richardson, who says that the operation is as certain to be immediately and permanently successful as any operation in surgery. Further, he suggests that a two-year interval of complete freedom from abdominal or digestive disturbances is sufficient to establish the probability of a permanent immunity. These remarks, however, do not apply to the after effects of operation for gallstones in the common duct. After such operations an interval of not less than five years of perfect health should ensue.—*Proceedings of the Twenty-first Annual Meeting of the Association of Life Insurance Medical Directors.*

Insurance Statistics and the Incidence of Cancer.—Malignant disease has but little practical importance for the medical examiner so far as the selection of applicants for insurance is concerned, because in the first place it is usually a disease of advanced age while most of the applicants are persons of early or middle age; in the second place, the etiology of cancer has not been at all cleared up, so that nothing is known which would determine what persons among applicants, young or old, may become victims of it after procuring insurance. On the other hand, insurance statistics add their data to the question of the increase in the incidence of cancer. The tables published by Gollmer of Gotha show that there has been a progressive increase of deaths from malignant disease in the period from 1829 to 1895. On the other hand, his tables show an almost parallel decrease of mortality from diseases of the esophagus, stomach, intestines, liver, pancreas, and bladder; that is, of organs that most frequently are the site of malignant disease. The increase in the incidence of cancer is therefore only an apparent one and is simply due to the more exact diagnosis made in the later periods. The Leipsic Life Insurance Company publishes later figures, having taken the periods 1864-1886 and 1887-1899 for comparison. These figures show that the mortality from malignant diseases in the ages from forty-one to eighty-five years is greater in the second than in the first of the two periods, but the increase is so small that it may likewise he explained by the advance in diagnosis and not by increase in the incidence of cancer.—*Blätter für Vertrauensärzte der Lebensversicherung*, January and February, 1910.

Intercostal Neuralgia from an Unusual Cause.—A certain applicant was insured at the age of twenty-seven, physical examination at the time showing a somewhat feeble and ill-nourished individual, otherwise being quite negative. Eight years later he applied for a larger policy. This time the examination showed little change from the first one, but the applicant gave the history of an intercostal neuralgia, which continued for six weeks and disappeared after a prolonged stay in a bathing resort. The medical examiner recommended the applicant for reinsurance, as pulmonary tuberculosis and any evidence of an aneurysm as possible causes of the neuralgia were excluded. The medical director, however, refused the applicant because of the fact that no change for the better so far as feebleness and ill-nourishment of the applicant had taken place in the interval between the two examinations. This applicant died in the course of the following year, having suffered from a left-sided pleurisy which later was shown to be caused by a suppurative focus in a rib cartilage. Later pus foci developed in other bones, among them in the vertebræ. The final diagnosis proved to be actinomycosis.—*Blätter für Vertrauensärzte der Lebensversicherung*, January and February, 1910.

Modern Sanitation.—At the fourth annual meeting of the Association of Life Insurance Presidents, held December 9 and 10, 1910, Alvah H. Doty, Health Officer of the Port of New York, presented a paper in which he contrasted the modern methods of sanitation with those traditionally in vogue. Cleanliness has ever been considered an important factor in the prevention of disease, receiving its first authoritative recognition in the Levitical code. Nevertheless superstition played an important rôle in ancient systems of sanitation, as evidenced by the use of incantations and the burning of magic powders. Even with the passing of superstition, the influence of fear was still manifest in the practices of burning houses and sinking ships, which were officially ordered as a means of checking the transmission of disease. Scientific sanitation began with the modern era of bacteriological investigation, and even within this period there may be discerned a gradual unfolding of more rational methods. In the early days of this era the "fomites theory" held sway: the theory that the clothing and baggage of the well no less than those of the sick were instrumental in the transmission of disease, dominated sanitary regulations. This theory has been shown to be fallacious, the influence of fomites in the transmission of disease occurs only in exceptional instances. It has been proved that in the majority of instances infection results from direct contact, or by means of infected water and food, or through the intermediation of insects. Recently the rôle played by "carriers," the apparently healthy harborers of pathogenic microorganisms, has been shown to be an important one in the propagation of infectious disease. The fact is emphasized that modern practical sanitation does not guarantee absolute protection, that health regulations are to be framed not to comply with rare instances, but to deal promptly and effectively with the common or ordinary modes of infection. As an example of the practical harmlessness of fomites, it is noted that employees of banks who are constantly handling old, filthy, and offensive money, are no more subject to infectious diseases than those who follow other callings. The safeguarding of public health demands the extermination of the mosquito, the fly, and other dangerous insects; the protection of water and milk supplies; the prevention of overcrowding and the provision of public baths, etc.; the destruction of the discharges of infected persons, and the performance of disinfection only under the direction of the physician or health official. Prevention is the keynote of modern sanitation.—*Proceedings of the Fourth Annuol Meeting of the Assaciation of Life Insurance Presidents, December 9 and 10, 1910.*

Suicide and Occupations.—Among men, day laborers and agriculturalists are least prone to suicide. Soldiers and sailors are most prone to it. It is common among saloonkeepers, brewers, cigarmakers, servants, architects, bankers, collectors, commercial travelers and druggists, tailors, journalists, and lawyers. Among employed women it is a prominent cause of death for telegraph and telephone operators, cigarmakers, and stenographers.

Book Reviews.

A Manual of Nursing. By Margaret Frances Donahoe, formerly Superintendent of Nurses, and Principal of Training School, Philadelphia General Hospital. Illustrated. New York and London: D. Appleton and Company, 1910.

This book contains twenty-eight chapters, and covers practically all the requirements of the trained nurse. In so far as it treats of nursing, the book is admirable; but, like most works of this class, it occasionally wanders a little into the fields of medicine and surgery, and then it is not quite so safe a guide. For example, after correctly saying that dislocations should be properly cared for till the doctor comes, the author adds "A finger or toe may be gently pulled into place, and a dislocated jaw may be set, etc." Those who have had any experience know full well that a dislocated thumb is not so easily dealt with. The "vesical bladder" is new to us, and seems to be somewhat redundant. A.c. and p.c. are generally said to be abbreviations of ante cibum and post cibum, rather than of ante coenatum and post coenatum (as here given). What "the salts of copper sulphate" may be, we do not know; nor were we aware that "the molecule of sugar was smaller than the molecule of starch, and consequently more easily soluble." It is hardly accurate to say that "Potts' fracture is a simple break of some part of the lower fifth of the fibula," or that "proteid consists of carbon, hydrogen, nitrogen, and sulphur"; both of these statements are partly correct. After a very sensible remark on the catheterization of male patients the author adds that if such an emergency arises "The nurse should be able to pass the catheter *without any previous instruction.*" Why will not this same intuition suffice in every other emergency?

A Manual of Chemistry. Theoretical and Practical, Inorganic and Organic. Adapted to the requirements of students of medicine. By Arthur P. Luff, M.D., B.Sc., Lond., F.R.C.P., F.I.C. Physician to St. Mary's Hospital and Joint Lecturer on Medicine at St. Mary's Hospital Medical School; and Hugh C. H. Candy, B.A.B.Sc., Lond., F.I.C.; Lecturer on Chemistry in the London Hospital Medical College. With 46 illustrations. New and enlarged edition. Price, $1.75. Chicago: Chicago Medical Book Company.

This is the fourth edition of Luff's Chemistry, and it has undergone considerable revision and some enlargement. Most of the changes have been made to adapt it to the changing requirements of the British examining boards. The first part of the book has been practically rewritten, and it forms a good introduction to the chief laws and principles of the science. Parts II and III deal with inorganic chemistry, and constitute the main part of the book. At the same time these are the most complete and satisfactory portions of the work. The part on organic chemistry is too brief for the requirements of the best medical colleges in this country; and physiological chemistry is practically absent. The word "proteid," or "protein," does not occur in the index, or (so far as we can ascertain) in the text. There are a few pages devoted to chemical problems, but we prefer this part as it was in the former edition. As an introduction, and for first-year work, this little book can be most confidently recommended.

Diseases of Children for Nurses, including Infant Feeding, Therapeutic Measures Employed in Childhood, Treatment for Emergencies, Prophylaxis, Hygiene, and Nursing. By Robert S. McCombs, M.D., Assistant Physician to the Dispensary and Instructor of Nurses at the Children's Hospital of Philadelphia. Illustrated. Second edition, thoroughly revised. Price, $2.00. Philadelphia and London: W. B. Saunders Company, 1911.

There is no branch of medicine requiring of the nurse a greater mastery of details and a more extensive knowledge of special methods of management and treatment than pediatrics. There is certainly none in which the common sense and tact of the nurse are more productive of success than in this branch. It is difficult to decide how much of the natural history of disease a nurse should know; at any rate the more comprehensive her knowledge of the diseases of children the more competent will she be in understanding the rationale of and hence in carrying out the numerous procedures that she is constantly expected to perform. For this reason a book that describes rather fully the characteristics of childhood and the various diseases to which children are subject, as well as the numerous dietetic and therapeutic requirements pertaining to this period of life supplies a distinct want. The present volume answers these requirements. It contains all and a good deal more that the average nurse should know about children, presented briefly without a sacrifice of clearness and precision. It contains numerous helpful illustrations, including several colored plates of the various exanthemata. The chapter on artificial feeding is particularly good, embodying the simplest methods, based upon hospital experience, of modifying milk according to the various formulae.

Hay Fever and Paroxysmal Sneezing. By Eugene S. Yonge, M.D.; Physician to the Manchester Hospital for Consumption and Diseases of the Throat, with two colored plates; pp. 150. $2. New York: William Wood & Co., 1910.

This book is divided into three portions: Hay Fever (pp.1-86), Paroxysmal Sneezing (Vasomotor Rhinitis (pp. 87-123), and Idiopathic Rhinorrhea (pp. 123-131). The book opens with an excellent historical sketch of hay fever. Then follow chapters on etiology, symptoms, and diagnosis, prognosis and treatment, with general considerations as to diet, mode of life, etc. The same general plan is followed in the remaining sections. Nothing essentially new is presented. It is interesting that the best results in the author's hands have followed the bilateral excision of the tubercle of the nasal septum. Other surgical procedures mentioned are the correction of intranasal deformities, the application of the galvanocautery or chemical caustics, partial or total turbinectomy, and resection of the nasal branch of the fifth nerve. The book is an excellent presentation of some of the interesting questions of present-day rhinology.

Plastic and Cosmetic Surgery. By Frederick Strange Kolle, M.D.; Fellow of the New York Academy of Medicine, etc. pp. xii, 511. Illustrated with one colored plate and five hundred and twenty-two figures in the text. New York and London: D. Appleton & Co., 1911.

This interesting book treats of plastic operations, subcutaneous hydrocarbon prothesis, and electrolysis in dermatology. Beginning with a short account of the history of plastic surgery, it devotes about seventy pages to general operative requirements. After this introduction to the subject in hand the author describes many operative procedures for accomplishing restorations of the eyelids, ears, lips, mouth, chin, and nose, and then discusses the methods and uses of electrolysis in diseases of the skin. Many of the operations are, as would be expected, well known, but new plans or modifications of old methods are here and there introduced. The book gives the impression that the author is more interested in the use of paraffin and similar substances for altering contours of the face and other regions of the human body than in operative surgery. Almost one-quarter of the volume is devoted to the description of these prothetic measures. The difficulties, risks, and precautions connected with such subcutaneous operations, and the means for obtaining successful corrections of contour are elaborately set forth. Many useful hints are given. The title of the book would lead one to believe that it dealt with general plastic reparations. It discusses, however, such operations on the face almost exclusively. The specialist and the general surgeon will find it worthy of perusal. It will open up to them and their patients some new fields of surgical endeavor which have been too little cultivated. If a new edition is published the author and proofreaders should scan with keen vision the terminations of the Latin words used. Tenaculi is not the plural of tenaculum (p. 451), and nare not the singular of nares (p. 468). The reference to "laudable" pus (p. 51) will seem to the present generation of medical men like a survival of the preantiseptic era of surgery.

An Introduction to Vertebrate Embryology. Based on the Study of the Frog, Chick, and Mammal. By Albert Moore Reese, Ph.D. (Johns-Hopkins), Professor of Zoölogy in West Virginia University. Second Edition, Revised and Enlarged. With 118 Illustrations. New York: G. P. Putnam's Sons, 1909. Price, $1.50.

As its title indicates, the present volume deals with the development of the ovum of the amphibian, the bird, and the mammal. Most of the works on general embryology are larger and more expensive than is necessary for the use of the beginner in this subject, and the book is well adapted to serve as a classroom guide supplementing lectures in which somewhat more detailed information is given. The text consists of concise descriptions of the stages of development, and is well supplied with illustrations. In its present edition it has been enlarged by the addition of a chapter of about forty pages in the embryology of the mammal, which increases the usefulness of the work for medical students.

The Practical Medicine Series, Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Under the General Editorial Charge of Gustavus P. Head, M. D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School, and Charles L. Mix, A.M., M.D., Professor of Physical Diagnosis in the Northwestern University Medical School. Volume VIII. Materia Medica and Therapeutics; Preventive Medicine; Climatology. Edited by George F. Butler, Ph.G., M.D.; Henry B. Favill, A.B., M.D., and Norman Bridge, A.M., M.D. Series 1910. $1.50. Chicago: The Year Book Publishers.

Over two-thirds of this small volume is given over to the consideration of materia medica and therapeutics, the rest of the book being devoted to preventive medicine and climatology. The therapeutic agents are arranged alphabetically. Some of the subjects discussed are: "Carbon Dioxide," "Snow in the Treatment of Nevi and Skin Affections," "Serum and Antitoxin Therapy," "Vaccine Therapy," "Bismuth Paste," and "Enzyme Treatment of Cancer."

Volume IX. Skin and Venereal Diseases; Miscellaneous Topics. Edited by W. L. Baum, M.D., and Harold N. Moyer, M. D. $1.25.

As so much has been written about syphilis during the last year it is but natural that more space be given to it than to any other subject. Ehrlich's "606" and the Wassermann reaction have been considered at some length. J. B. Murphy reports almost as good, if not as striking, results from the hypodermic use of sodium cacodylate in doses of 1 to 2 grains, as have been obtained from the use of salvarsan. The miscellaneous subjects considered are: "Medical Education and the History of Medicine," "Biography; Life Insurance," "Medico-Legal," "State Control of Medical Practice," and "Vivisection."

Volume X. Nervous and Mental Diseases. Edited by Hugh T. Patrick, M.D., Professor of Neurology in the Chicago Polyclinic, Clinical Professor of Nervous Diseases in the Northwestern University Medical School, ex-President Chicago Neurological Society, and Peter Bassoe, M.D., Assistant Professor of Nervous and Mental Diseases, Rush Medical College. $1.25.

This book opens with a few pages devoted to the symptomatology of nervous diseases. Then follow articles on the various neuroses, diseases of brain, meninges, spinal cord, and peripheral nerves, miscellaneous and mental diseases. The book is full of interesting and instructive articles and, like the rest of the volumes of this series, will be found very useful to the specialist and the general practitioner.

A Handbook of Practical Treatment. By Many Writers. Edited by John H. Musser, M.D., LL.D., Professor of Clinical Medicine in the University of Pennsylvania, Philadelphia, and A. O. J. Kelly, A.M., M.D., Assistant Professor of Medicine in the University of Pennsylvania, Philadelphia. Volumes I and II. Price per volume, $6.00. Philadelphia and London: W. B. Saunders Company, 1911.

The recent untimely death of Dr. Kelly, one of the editors of this work, imposes upon the reviewer the sad duty of paying a tribute to the memory of one whose distinguished services in furthering the progress of medical science had already shed lustre upon his name. The termination of his career at the zenith of his activities was all the more pathetic in that he could not behold the complete publication of a work in the execution of which he had so ably shared. Two of the three volumes have already been published. The keynote of this work is the study of medicine as an art—the emphasis of the physician's function from the patient's point of view, the preservation or prolongation of life and the mitigation of suffering. With this aim the most modern and advanced views are presented in regard to the management of diseased states. In order to gain a fair conception of the scope of this work one need only glance over the table of contents, noting the various subjects and long list of distinguished authors. Volume one consists of the following: "The Fundamental Principles of Therapeutics," by John H. Musser; "Preventive Treatment," by Charles H. Harrington, revised by A. C. Abbott; "The Dietetics of Infancy," by Maynard Ladd; "The General Principles of Drug Treatment," by Sir Lauder Brunton; "The General Principles of Serum Therapy" by Ludwig Hektoen; "The General Principles of Organotherapy," by Warren Coleman; "The Rest Cure, the Work Cure, and Psychotherapy," by Charles W. Burr; "Exercise, Massage, and Mechanotherapy," by R. Tait McKenzie; "Hydrotherapy and Balneotherapy," by Guy Hinsdale; "Climatotherapy and Health Resorts, and Artificial Aerotherapy," by Henry Sewall; "Electrotherapy," by J. Montgomery Mosher; "Radiotherapy," by Henry K. Pancoast; "Miscellaneous Therapeutic Measures," by George P. Müller; "The General Care and Management of the Sick and the Treatment of Slight Ailments," by M. Howard Fussell; "Food Intoxication and Poisoning by Reptiles and Insects; Drug Poisonings and Drug Habits," by Horatio C. Wood, Jr.; "Sunstroke," by James Tyson; "Diseases of the Blood," by Richard C. Cabot; "Diseases of the Lymphatic System and Diseases of the Ductless Glands," by George Dock, and "The Surgical Treatment of Diseases of the Thyroid and Parathyroid Glands." One notes from this enumeration of titles that the old-time conception of therapeutics as equivalent to drug treatment has been supplanted by the more modern one of diet, exercise, mechanical methods, electricity, vaccines, etc., in addition to drugs; the discussion of the dietetic, physical, serological, and organotherapeutic methods takes up the greater part of the first volume. It would be difficult to pick out any one chapter for special commendation. All the topics are fully presented by experts in their particular field.

The second volume is devoted to the special treatment of many local and general diseases, and, like the first, is made up of contributions from men well known in their particular field. The contents of this volume are as follows: "Diseases of the Cardiovascular System," by Sir Clifford Allbutt; "The Surgery of the Heart," by Clinton T. Dent; "Typhoid Fever," by Rufus I. Cole; "The Surgical Complications of Typhoid Fever," by John M. T. Finney; "Pneumonia," by Hobart Amory Hare; "Diphtheria, Scarlet Fever, Measles, and rötheln," by George H. Weaver; "Intubation and Tracheotomy in Diphtheria," by John H. Jopson; "Tuberculosis," by Edward O. Otis; "Toxemia, Septicemia, and Pyemia," by Richard M. Pearce and Arthur W. Elting; "Syphilis," by J. William White and Alfred C. Wood; "Gonococcic Infection," by Edward Martin; "Vaccinia Variola and Chicken Pox," by Jay F. Schamberg; "Cerebrospinal Fever, Cholera Asiatica, and Plague," by Lewellys F. Barker; "Yellow Fever and Dengue," by James Carroll; "Influenza and Rheumatism, or Rheumatic Fever," by Alfred Stengel; "Tetanus, Rabies, Anthrax, Glanders, Actinomycosis, Madura Foot and Foot-and-Mouth Disease," by Joseph C. Bloodgood and Alexius McGlannon; "Pertussis, Mumps, Miliary Fever, and Glandular Fever," by Samuel McC. Hamill; "Dysentery," by Charles F. Martin; "Leprosy," by Isadore Dyer; "Typhus Fever," by John F. Anderson; "Tropical Diseases," by M. J. Rosenau and John F. Anderson; "The Ocular Complications of the Infectious Diseases," by Charles W. Richardson; "The Surgical Treatment of the Joint Complications of the Infectious Diseases and Animal Parasites," by David Riesman. As in the first volume, it is difficult to pick out any one topic that deserves special commendation, all parts fully covering their particular field, and written with a fullness of detail demanded by the everyday needs of the practitioner. One may regard this work as a collection of monographs on the many phases of treatment. The diseases of the cardiovascular system are amply covered in 175 pages of text; typhoid fever is given 92 pages, and tuberculosis 119 pages. The other subjects are accorded a space commensurate with their importance. In illustrations, type, paper, and binding this work is an example of consummate bookmaking.

Personal Hygiene and Physical Training for Women. By Anna M. Galbraith, M.D., Author of "Hygiene and Physical Culture for Women" and "The Four Epochs of Woman's Life"; Member of the New York County and State and the American Medical Associations; Fellow of the New York Academy of Medicine; ex-President of the Alumnæ Association, Woman's Medical College of Pennsylvania; former Attending Physician, Neurological Department, of the New York Orthopedic Hospital and Dispensary; late Attending Physician and Instructor in Diagnosis and Clinical Medicine at the Woman's Medical College, New York Infirmary. Illustrated. Cloth, $2.00. Philadelphia and London: W. B. Saunders Company, 1911.

As the author says in the preface, the aim of this book is the clear and concise presentation of the fundamental physical laws that form the true cornerstone of all personal hygiene. Then follow naturally practical, definite instructions for the training of the body by simple hygienic methods, utilizing fresh air, tonic baths, suitable clothing, food, and exercise. By these means will the entire system be put in such condition that it will be able to resist disease. Hydrotherapy, the care of the skin, the digestive, respiratory, and nervous systems, mental hygiene, dress, physical training, and symmetrical development are among the topics discussed. The material is well handled and engages the reader's interest while the spirit of the whole is scientific. The book is sure to prove of value to girls and women of all ages.

Society Reports.

AMERICAN PEDIATRIC SOCIETY.

Twenty-third Annual Meeting, Held at Lake Mohonk, N. Y., May 31-June 1, 1911.

THE PRESIDENT, DR. HENRY DWIGHT CHAPIN OF NEW YORK, IN THE CHAIR.

Wednesday, May 31—First Day.

President's Address.—Dr. HENRY DWIGHT CHAPIN of New York delivered this address. He chose for his topic "The Fundamental Principles of Pediatrics." He stated that pediatrics might be divided into two parts: first, that relating to the treatment of disease and perversion of function; secondly, that which was concerned with the production of well developed physique in children. If its scope were broadened pediatrics might be defined as that branch of science which concerned itself with the animal aspect of the protection of human beings. The science could then be divided into two parts: first, that devoted to the production of the highest development of the human being as an animal; secondly, that concerned with the management and care of the human being when malformed, or when afflicted with perverted function, or subjected to mechanical injury, or attacked by parasitic microorganisms or poisons. It would be greatly to the advantage of the parents, the child, and the community at large if every child, during its first period of growth, were supervised by a pediatrist. It would be to the advantage of every physician if the fundamental principles of the management of infancy could be firmly established. To attain this result it was essential that the teachings concerning chemistry should be in accord with the general science of chemistry, that the problems of infancy following those of physics be recognized as such, and that the teachings concerning animal life and development be true to those principles which had been found to apply to animal life in all its forms. An infant taking in thirty-six ounces of breast milk daily received food yielding 792 calories, or enough heat to raise the temperature of a fourteen-pound baby to 113° C. It might easily be appreciated then how important was the working of the infant's cooling apparatus, or system. Few realized that animals had cooling systems and that a large part of the sickness occurring in infants during the hot weather might be due to defective cooling. When an infant lay in a crib surrounded by curtains on a hot day the air movement was stopped. One could be kept cool by a current of hot air if a wet cloth was kept next to the skin. If an infant had been subjected to conditions such as rendered it unable to eliminate heat properly, the treatment should consist in stopping all food temporarily, giving baths to remove the heat, keeping the patient quiet to prevent the expenditure of energy, and sending him to the country where the air was cool, or dry, or in motion. Dr. Chapin emphasized the importance of fresh air and said that this could not be looked upon as a hobby. The dignity and importance of pediatrics must be made clear to the profession and to the public. It offered a most promising field for advanced work in scientific and experimental medicine. The general and broad methods of science at large should be applied to the solution of its problems.

A Study of One Hundred Infants from Birth to the End of the First Year.—Dr. CHARLES HERRMAN of New York said the work was originally undertaken for the purpose of determining what could be done in lowering the mortality in a series of infants by advising the mothers and supervising the infants from their birth. However, as the work progressed, it became apparent that other valuable data could be obtained. Although everyone recognized the important role played by predisposition in the causation of disease, it sometimes seemed as if outside agencies were given too much and the peculiarities of the individual too little consideration. From June 1, 1909, to June 1, 1910, 172 babies were born in the Lebanon Hospital. These mothers were instructed in the care and feeding of infants and a printed form containing a few of the most important points was given to them to assist the memory. Special emphasis was placed on the importance of breast feeding. They were also given a card to the pediatric department, and requested to return within ten days after leaving, etc. The total number of infants born was 172; the deaths during the first year numbered 14; the number followed for more than one year was 125. There were 100 males and 72 females. Those who were exclusively breast-fed for five months or more gave a percentage of 66; those who were partially breast-fed for five months or more, gave a percentage of 83.

The speaker demonstrated on the history charts of a number of cases the following points: (1) Breast milk might be made to reappear in a breast that had not functionated for more than two months. (2) A mother might believe that she had not sufficient breast milk when as a matter of fact she had more than enough. (3) The great importance of proper advice to counteract the improper advice of neighbors. (4) An infant might show an insufficient gain in weight during the first three months, although the food, breast milk or artificial, might be of proper quality and quantity. At about the third month, on the same food, the infant would rather suddenly gain much more rapidly in weight. (5) Cases presenting at different times during the first year the characteristic manifestations of the "exudative diathesis," with recurring attacks of loose mucous stools as one of these manifestations. (6) The importance of a babies' ward to which the very sick cases could be referred, and the necessity for having breast milk for the extremely bad cases. (7) Breast feeding might be possible in an infant even when several preceding infants of the same mother were artificially fed. In the entire series of infants there were 14 deaths, 9 male and 5 female. Eleven, or 80 per cent., were first children. Only 33 per cent. of the entire number, 172, were first children. This illustrated in a very striking way the greater mortality in the firstborn. Six of the deaths were in premature infants; one an instrumental delivery; one a cesarean section; and one a twin. Six of the deaths occurred during the first two weeks of life; four of these were premature infants. Not a single death occurred in an infant that was breast-fed for more than five months. None of those that died were breast-fed at the time of death.

Recurrence of Scarlet Fever.—Dr. J. P. CROZER GRIFFITH of Philadelphia said that recurrence of the typical forms of scarlet fever were a rarity. Their occurrence, however, was supported by the testimony of many writers. Little was said about these recurrences in the textbooks and but few instances were reported in the literature. The speaker reported the case of a boy who had nose bleed and vomiting. The following day he did not appear to be at all ill, though he vomited again in the afternoon. On the following day a scarlatiform rash appeared over the thorax and abdomen. The scarlet fever ran a mild course, efflorescence disappearing during the first week of the illness. One week later he began to cough and had a well defined attack of measles. Thirteen months later he again became ill and was covered with a typical scarlatiform rash. The speaker would not have believed that this was true scarlet fever had it not been for the final desquamation. There also developed a post-scarlatinal nephritis.

Duodenal Ulcer in Early Life.—Dr. J. P. Crozer Griffith said that this condition was such a rare one that even the text books, at least the majority of them, took no notice of it whatever. Duodenal ulcer might be the cause of melena neonatorum. These ulcers were often observed in atrophic infants. In early life the condition was an exceedingly rare one.

The speaker reported two cases, the first of which was uncertain, not coming to autopsy. Case I: This patient was ten years of age and had suffered from scarlet fever measles, and nephritis. He ate indigestible food which was followed by vomiting. Calomel was given and recovery resulted. The day following exercise on a trapeze, though there was no history of any pressure on the abdomen, he was seized with dizziness and faintness. The following day he vomited and had several loose bloody movements without any pain. On the two days following the bloody stools continued and the patient was very pale and much nauseated. He had on fever. The percentage of hemoglobin was 70 per cent. and the corpuscles were in proportion. Dr. Musser was called in consultation and diagnosed a duodenal ulcer. With proper dieting the boy improved and made a gradual recovery. Case II: This was a child six months of age who began to suffer after having been fed artificially for four weeks. Constipation developed and there was a discharge of very hard feces. A milk mixture rich in fat was given. Blood soon appeared in the vomited matter and there were dark bloody stools. Following this the child went into collapse, became moribund, and was sent to the hospital, where he died. At autopsy an ulcer was found just below the pylorus, measuring about five mm. in diameter. There was no stenosis at the pylorus.

Means of Protection Against Contagious Diseases in Hospital Work.—Dr. William P. Northrup of New York read this paper in which he described certain appliances in use at the Presbyterian Hospital. The "Grille," or bed screen, consisted of a three-leaf wire screen with two-way hinges; it was four feet high and each leaf was three feet wide. Two such screens would entirely enclose a child's bed. The psychological effect of such a screen was such as to indicate unmistakably that no one was to approach. Nurses could reach over this screen for many purposes in ward work and their clothing was protected from contact with the bedding. They acted upon the conviction that the infecting agent in contagious diseases was transferred by contact or very near approach and that even a few feet rendered the infected patient harmless to his neighbors. It was to be hoped that this lesson would ultimately reach the laity. The speaker next showed photographs of the examination table which enabled the physician to work with comfort. The head of the table could be raised or lowered, rendering the table useful in intubations, aspirations, punctures, etc. He then showed a photograph of a crib warmer, consisting of an asbestos box which contained an electric heater. Above this was an asbestos trough in which rested the bassinet. It was easy to regulate the heat, and the electricity from an ordinary 16-candle power illuminating bulb was sufficient. It might taken the place of the usual incubator for newborn babies. Dr. Northrup also described their method of bathing children. The requirement was a warm washing, dressing and changing room, the atmospheric temperature being 75° F. or more. Everything was kept warm—clothing, diapers, towels and water. The arrangement was such that there was no possibility of scalding or infection. The bathtub had been abolished as it was suspected of being a great source of infection, and marble slabs sloping to a sink had been substituted, with sprays for cleansing the skin. The baby was laid on a clean bath towel covering the marble slab, and after being sponged with liquid soap, was sprayed and then dried and dressed. The facilities presented had been the result of much studious attention on the part of the heads of the various hospital departments and the result was that the babies were washed in at least half the time formerly consumed and the danger from infection and accidents from overhot water had been eliminated.

Hospitals for the Care of Infants and Children and the Methods of Prevention of Infection.—Dr. Henry Koplik of New York presented this paper. He stated that one of the most interesting questions in connection with the hospital care of infants and children was the prevention of infection. Mild infections at birth or in early infancy received much greater care and consideration than at a later period of life. Hence in hospitals the question of the separation of infants of a tender age from older children was a very important one. The speaker described the institution of Dr. Keller in Berlin and the Augusta Victoria Haus where only infants under one or two years of age were cared for. The conditions in Dr. Keller's institution were ideal; the wards were bright, cribs far apart, clothing and linen immaculate and the nursing personnel of a high order. In this institution infections were rare, there having been only one case of vaginitis in two years. The only approach to an epidemic that had occurred was the development of three or four cases of a pertussis-like cough in premature infants. This infection was quickly controlled. Here the much vaunted box system was unnecessary, the isolation of one patient from another was accomplished through intelligent cooperation of a careful and conscientious nursing personnel. Each infant had a thermometer and other utensils for its own use. The confinement room in connection with this hospital was distinguished by its simplicity, which was in marked contrast to the gaudiness seen elsewhere. There was also a department which looked to the care of the infants after they were discharged from the hospital, called the "Säugling's Fürsorge" (Child's Welfare). There was a similar department in some of the New York hospitals, but they bore no comparison to that of Keller's institution. The speaker next described the box system of construction in the French hospitals. This system consisted of separating beds by partitions of steel and glass, the partitions reaching to the ceiling in some instances and being only six feet in height in others. The former was used principally for diphtheria, where a closed box was needed for flooding with steam or chemicals. With this system it was easy to hold mixed infections in check. The highest development of the box system was seen in the Pasteur Hospital which was constructed throughout on the box plan. The box system might be looked at from several points of view and the impression on the whole was not satisfactory when one had visited an institution like that of Keller, in which no boxes existed and in which infections were extremely rare. The author felt that given good conscientious nursing and care in the matter of details the box system was unnecessary in a noncontagious hospital. It was, however, a potent barrier to contact infection and also to infection in the immediate vicinity of the patient. A ward such as that of Lasage in which boxes were open at the top was a very potent argument against the so-called atmospheric mode of infection. If infectious diseases could be practically treated in the same ward in the manner indicated one had in the past certainly overestimated the importance of the atmosphere in conveying infection. In surgical wards the box system would be a boon in emphasizing the isolation of one child from another. In such wards simple partitions as seen in Heubner's box ward would serve all purposes and would not interfere with the free circulation of light and air. In the treatment of the exanthemata and of diphtheria the box was not only a means of cleanliness, but prevented reinfection and mixed infections.

A study of the system at the Pasteur Hospital led to the conclusion that they had solved the problem of the prevention of mixed infections. In ten years the number of infections in the hospital proper was 30 in an aggregation of 9,677 patients. Most of these infections could be accounted for by infringement of the rules laid down for the management of the patients and boxes. Taking scarlet fever, the mortality below two years of age in 71 cases was 8.4 per cent.; from 2 to 14 years of age, 798 cases gave a mortality of 6.9 per cent.; measles in 245 cases below two years of age gave mortality of only 9.8 per cent.; 200 cases from two to 14 years of age gave a mortality of 1.10 per cent.; 309 cases of diphtheria under two years of age gave a mortality of 20 per cent.; 437 cases from two to 14 years of age gave a mortality of 6 per cent. The speaker said that he knew of no such favorable statistics elsewhere. The old system of general wards was a thing of the past. In constructing children's wards today it would be wise to have, in connection with a service where non-contagious diseases were treated, several boxes for the immediate isolation of scarlet fever or measles which might break out in general wards. A study of the Pasteur system was a convicing argument against the potency of atmospheric infection. In the Pasteur system, while the same nurses cared for different contagious diseases, they washed their hands and changed gowns before entering each box.

Dr. William P. Northrup of New York, in discussing the three papers just read, asked Dr. Holt and Dr. Koplik whether they believed in the danger of the Klebs-Loeffler bacillus in the nose of patients not having diphtheria and of vaginitis with the presence of the gonococcus by smear without any discharge. The speaker thought that the presence of the diphtheria bacillus without lesion or that of the gonococcus without discharge was not very dangerous..

Dr. L. Emmett Holt of New York related the case of a relative in whom there was a recurrence of scarlet fever, the first attack being at the age of seven or eight and the second at the age of twenty-four. Both were severe and typical. In regard to Dr. Northrup's question, the speaker said it had been his custom to exclude cases which showed the presence of the Klebs-Loeffler bacillus from the ward only when a lesion was present. They had constructed a series of alcoves having marble slabs four and one-half feet in height and projecting about one foot from the foot of the bed. There were four or five of these in each ward and they put children of this class into these alcoves. They had come to fear these cases less and less, but they were subjected to close scrutiny. As to the danger of vaginitis, where there was no discharge, but only the presence of the gonococcus, the cases were watched very closely. In these cases they had given up the use of napkins and had used absorbent cotton covered by a piece of gauze. This procedure had done much to reduce the frequency of these infections. The speaker said that as far as his experience went the worst infections in hospitals were those of the respiratory tract, and their great problem was how to prevent these. They now put cases having a good deal of cough and bronchial secretion into alcoves. There should be an observation room where cases of a suspicious nature could be watched before admission to the general wards.

Dr. Charles Gilmore Kerley of New York reported two cases of recurrence of scarlet fever, one, a girl twelve years of age, the daughter of a physician, who was seen both times by an inspector of the Health Department; the other was a boy whom the speaker had seen in the second attack and both the doctor and the attendant stated that the child had desquammated freely after the first attack. The second attack was unquestionably a true one.

Dr. Abraham Jacobi of New York stated that in his long life he had seen but two instances of recurrent scarlet fever, but they were decided cases and he had seen both attacks. There were fever, eruption, and desquamation and in one of the cases, nephritis. So far as vaginitis was concerned, the speaker was of the opinion that there was nothing more dangerous. There would be relapses every few months. In the uterus of a young child there were furrows and wrinkles and in these the gonococci hid and they might not show their presence for two or three months at a time. He had seen cases lasting for years and seemingly incurable. The precaution of examining children for this trouble once a week was important. As to the presence of the Klebs-Loeffler bacilli they should be careful in discriminating between whether the bacilli were found on mucous membrane that was intact or on that which was not intact, and this was difficult. The bacilli were not dangerous unless there was a catarrh that allowed them to penetrate into the mucous membrane. There was no more dangerous thing than nasal diphtheria and forty years ago almost every case was fatal. They had modified this by keeping the nose washed out. Dr. Jacobi could not say whether it was necessary to isolate every child in whose nose or throat the diphtheria bacilli were found.

Dr. Thomas Morgan Rotch of Boston said that while the presence of the diphtheria bacilli in the nose was not dangerous to the individual as long as there was no lesion of the nasal mucous membrane, yet it was possible that these cases might be carriers. They had had cases where such children were isolated and the nurse caring for the child had contracted diphtheria. They could not state beforehand which individual child had some nasal lesion.

Dr. J. Lovett Morse of Boston said that their experience with these cases of diphtheria bacilli in the nose had been that these children were dangerous to those about them. At the Infant's Hospital they had been immunizing all the babies that came into the hospital as soon as the disease was discovered. As to the box system, the speaker said he had had no personal experience with it, but it had always seemed to him that it was bad for the patient in the boxes as it was difficult to provide proper ventilation and the patients were more liable to reinfect themselves. They were building a new child's hospital in Boston and had adopted the method of building pavilion wards of ten beds and two isolation rooms, so that if there was a doubtful case it could be put into one of these rooms. They were going to have two unoccupied wards so that if a contagious disease developed in a ward they could stop admission to that ward and open another one.

Dr. P. J. Eaton of Pittsburgh stated that his own family history recorded that he had had scarlet fever twice. He had recently discharged a little girl who had had true measles twice and German measles once. In the attacks of true measles she had been under his observation from the beginning.

Dr. Churchill of Chicago considered the question of latency in relation to gonococcal vaginitis. They had all seen instances where after not having a case for months one developed out of a clear sky. At the Child's Memorial in Chicago they had sent social workers into the homes of the children and in a large number of instances found that there had been gonorrhea in other members of the family and they now asked the question as to the presence of venereal disease in the family. They took smears twice a week of every girl patient who came into the hospital. They were building a new pavilion to their hospital after much the same plan that Dr. Morse had described.

Dr. Augustus Caillé of New York said that his twenty-five years' experience in trying to keep infection out of children's wards had convinced him that it was

mainly contact infection with which they had to deal. Twenty years ago Dr. Bouche of Berlin had said at an international congress: "I am not afraid of diphtheria; I put a fence around it and diphtheria cannot jump more than six feet." If they were going to keep the wards clean they must keep the surgeons out with their nose, throat, and ear cases. The moment they put those cases with a free discharge in the wards there was trouble.

Dr. G. R. Pisek of New York said that if they could get the bacteriologist to determine by some more ready method than was known at present in regard to the virulence of the bacilli they could decide which cases were dangerous to other children.

Dr. Blackader of Toronto confessed that he would not like to depend upon these boxes or screens. Until they could examine and differentiate between these cases better than at present he preferred to have something more than a partition between them.

Dr. W. P. Northrup of New York said there seemed to be confusion of terms. He had referred to a screen, not a fence. In the Paris hospitals they had the grille and also the box. At the Presbyterian Hospital they took individual precautions in all cases in which the Klebs-Loeffler bacilli were found in the nose. Every patient who was in bed was isolated, although only four feet from his neighbor.

Dr. Thomas S. Southworth of New York said that the questions brought up applied very strongly to institutions other than hospitals. It was of the highest importance that in institutions where the children were presumably well they should be protected from infection. The idea of building a ward with room for only ten beds was a step in advance. It was advisable to make them even smaller than for ten beds each. It had been the speaker's experience that the mortality had not been as great from the ordinary exanthemata as from respiratory infections, especially the influenza types of which Dr. Holt had spoken. For the past three winters practically the only infection had been from that type and particularly among the bottle-fed infants. It seemed that the only way that the spread of infections in institutions could be remedied, if not by the plan of alcoves or grilles, was to reduce the size of the wards. Their president had recently written a very able article in which he spoke of the fact that the death knell of institution life for infants had been sounded.

Dr. Samuel S. Adams of Washington said that he believed he was responsible for the discussion of the question of the recurrence of scarlet fever as he had raised it at the last meeting. Since a man of such wide experience that he was now attending the grandchildren of patients that he had attended in their infancy had seen only two cases of recurrence of scarlet fever it must be a very rare occurrence. In regard to the ward problems, the question that arose was how much air the the occupants of the boxes were going to have. It was not well to pen up a patient in this way without plenty of air. The question also arose as to how to keep the children who were running about the wards within bounds.

Dr. Northrup replied that that was where the screens came in.

Dr. Adams rejoined that the children would go behind them. Another factor was that in some hospitals there was a strong sentiment against the use of screens.

Dr. L. E. LaFetra of New York said that while scarlet fever was the subject before the meeting, measles had been referred to and he wished to say that he had seen two cases of recurrence of measles. In one of these children he had seen both attacks. He believed, however, that it was very unusual to see measles occur twice in the same patient.

Dr. R. G. Freeman of New York mentioned one modification of the box system to which no reference had been made. In one of the largest hospitals in Paris they had separate wards for contagious diseases, but in each ward they had glass enclosures in which they put suspicious cases to remain until a definite diagnosis had been made.

Dr. Koplik of New York recalled that he had described the system of ventilation on the Pasteur Hospital as being perfect. These cells communicated with the outside air by means of windows and there was also a fan system of ventilation. If they found the Klebs-Loeffler bacilli in the nose or throat of a patient with no symptoms of diphtheria, they put the patient in an outside room and the nurse took proper precautions. They did the same with other infectious diseases. There was then no reason why a very sick patient should be sent away from the hospital. They never refused a very sick child with vaginitis if it could be helped. He had recently put a child with this affection in a general ward, labeled the bed, took proper precautions to prevent the spread of the infection, and there were no bad consequences. If there was no discharge the staff were forbidden to touch the child as it disturbed her unnecessarily.

Dr. Churchill asked what was the objection to taking a smear?

Dr. Koplik replied that he believed in treating these children as they would want their own children treated.

Dr. Northrup of New York stated that he would not hesitate to treat scarlet fever in a ward with their grille. As to the desquamating cases, he did not fear them so long as the nose and throat were all right and there was no ear discharge. He did not believe the old traditions about scarlet fever being sent by a letter from the child to its parents.

The Treatment of Sepsis in Scarlatina with Antistreptococcus Serum.—Dr. Matthias Nicoll of New York presented this paper in which he stated that by the term "sepsis in scarlet fever" he desired to be understood a set of clinical symptoms occurring forty-eight hours or longer after the onset of the disease and apparently due to invasion of the body by organisms of the streptococcus group. These organisms might or might not be found in the blood. Scientific observers seemed inclined to disregard the possibility of streptococci representing anything more than an invasion of the secondary organisms upon a soil suitably prepared by some unknown agent. If this view proved to be correct it must be confessed that certain well authenticated phenomena were rendered difficult of explanation. Of these might be mentioned the undoubted success of vaccination with killed streptococci from scarlet fever as a means of preventing the latter. The speaker's experience had been obtained at the scarlet fever hospital of the New York Board of Health. The serum used consisted of eleven strains of streptococci from scarlet fever patients, blood, throat, glands, etc., and one streptococcus from a case of puerperal sepsis. Owing to a limited supply it was considered advisible to use but 50 c.c. as an initial dose. This precluded the possibility of comparison with European results. Only 30 cases were injected, of which 17 died. Of those that died, four were brought in in a moribund state. One died two hours after receiving the injection. Two others died within twelve hours, a length of time too short for any relief from a subcutaneous injection. One patient contracted measles and ileocolitis. In another case measles was followed by gangrenous varicella. There were other cases complicated by diphtheria; they failed to yield to large doses of antitoxin following the administration of the serum. Dr. Nicoll said that he was not prepared to recommend the general use of the serum except in those cases in which a delay of twenty-four hours would probably determine a fatal outcome. Here the intravenous injections were to be preferred. He presented

the apparatus which he used for inspection. While his experience was limited Dr. Nicoll said he felt that in a disease over which they had so little control the serum, if obtainable, should be used in full doses without delay.

The Therapeutic Utility of Diphtheria Antitoxin, with Remarks on Anaphylaxis and the Feasibility of a Scratch Test.—Dr. Augustus Caillé of New York presented this paper in which he stated that the use of diphtheria antitoxin had lowered the mortality in all kinds of cases, mild and severe, at least 50 per cent. The principal reason for the present-day mortality lay in the fact that they did not sufficiently recognize the great divergence of the clinical manifestations of diphtheria and, furthermore, that they had failed to educate the public along these lines. Primary pharyngeal, or tonsillar, or laryngeal diphtheria showed a great uniformity in behavior under repeated doses of from 3,000 to 5,000 antitoxin units. With good hygienic management and energetic and early specific treatment the mortality was not much more than 5 per cent. In the presence of a visible pseudomembrane or exudate, if they waited for a confirmatory laboratory report before the administration of antitoxin, the mortality would be 12 or 15 per cent. The experienced physician knew that it was impossible to distinguish between tonsillitis and diphtheria and that it was useless to wait for a confirmatory laboratory report. A running nose, a thin blood-colored greenish discharge, an excoriated upper lip, followed in the course of a week by croupy and stridulous breathing, and finally cyanosis were very suggestive of the disease. During this time the pharynx might be free from pseudomembrane and pale in appearance. The experienced doctor recognized the clinical picture of nasal diphtheria and extinguished the smoldering flame with a few doses of antitoxin. When diphtheria was complicated by scarlet fever or measles one or two doses of antitoxin would certainly counteract a part of the sepsis and might turn the tide in favor of the patient. In such cases it was extremely unwise to wait for a laboratory report. It was generally appreciated that certain forms of bronchopneumonia and pleuropneumonia could be favorably influenced by diphtheria antitoxin. Whooping cough might be complicated by a visible throat diphtheria. Antitoxin was indicated as soon as the slightest visible throat or nose exudate was in evidence. In ulcerative stomatitis and noma one should look for the diphtheria bacilli, suspecting a mixed infection. Such cases usually ran their course with clinical findings negative as to diphtheria. It was wise in such cases to give a few doses of antitoxin. Immunizing injections should be made only with serum other than that which came from the horse. Dr. Caillé concluded that they should widen the scope and application of diphtheria antitoxin; that they should apply a scratch test to detect hypersusceptibility in the prophylactic application of the serum; that they needed an animal serum other than that from the horse, or an antitoxin not associated with albumin to avoid anaphylactic shock.

Dr. Edwin E. Graham of Philadelphia said that he had recently looked up the subject of anaphylaxis. In the Widener Memorial Hospital for Crippled Children the patients were apt to remain for a long time. In spite of the greatest care a case of diphtheria would occasionally gain entrance and it was the practice to give an immunizing dose of antitoxin. As a consequence many children in the institution had at varying periods of six months or a year doses of 1,500 or 2,000 units of antitoxin and no injurious effects had been observed. In investigating anaphylaxis at the Municipal Hospital in Philadelphia, where there were records of children admitted two or three times and receiving an immunizing dose, in an experience covering years, no evidence of anaphylaxis, except in the very mildest degree, had been observed.

Dr. G. R. Pisek of New York thought that in discussing the subject of anaphylaxis one should bear in mind what constituted a foreign albumin. It seemed to the speaker that one should use antitoxin only in suspected cases and not in all cases unless there was a definite reason for it.

Dr. J. Mason Knox of Baltimore said that he was interested in the suggestion of a scratch test as a means of opening our eyes to the possible effect of horse's serum. In rabbits they found that they obtained a reaction, with all the local skin signs, and that this reaction could be prevented by an injection of some strong oxidizing agent. This could be done to some extent with dogs. The skin reaction was closely related to anaphylactic shock, but somewhat different from it. If the patient was susceptible to the skin reaction he doubted whether he would be susceptible to a subsequent injection of horse's serum.

Dr. Snow of Buffalo agreed with the speaker who had said that antitoxin should not be used unless there were definite symptoms. He had a sore throat and received 3,000 units of antitoxin. Three years later he was exposed and received 1,500 units. This was followed by erythema and urticaria, which lasted thirty-six hours.

Dr. Matthias Nicoll of New York said that in the Foundling Hospital and in the Scarlet Fever Hospital dozens and dozens of children had received more than one dose and there had never been a case of anaphylaxis. He feared physicians were getting hysterical on this subject.

Dr. Charles Gilmore Kerley of New York said that at the Nursery and Child's Hospital they had to take in every case of diphtheria the city sent, and with every case the children received from 500 to 1,000 units of antitoxin; if another case came in they had another injection. It seemed to Dr. Kerley that there could be no great danger or they would have seen something of it by this time.

Dr. John Ruhräh of Baltimore agreed with Dr. Kerley that it was a great mistake to lay too much stress on this idea of anaphylxis.

Dr. P. J. Eaton of Pittsburg had also used antitoxin in scarlet fever in cases having a bad throat condition and had seen the disease end by crisis.

Hypertrophic Pyloric Stenosis in Infants.—Dr. Henry L. K. Shaw and Dr. Thomas Ordway of Albany presented this communication. Pyloric stenosis might be defined as an affection occurring in young infants and characterized by forcible vomiting, constipation, visible peristalsis, and frequently a palpable tumor at the situation of the pylorus. Contrary to most affections of the digestive tract, pyloric stenosis nearly always occurred in breast-fed infants. The earlier writers considered it a congenital organic defect due to excess of development. Later writers were almost unanimous in the opinion that there was an hypertrophy or a muscular hyperplasia as a secondary manifestation. The condition progressed slowly and might last from three to twenty months. The dietetic treatment consisted in the use of breast milk if possible. If the milk contained too much fat it should be allowed to stand for a few hours and the fat should then be removed. It was best to give small amounts of food at frequent intervals. Feeding by gavage should be employed in many cases. The stomach should be washed out several times a day with cold water. Treatment by means of drugs was very unsatisfactory. Surgical treatment should be resorted to when no further improvement could be obtained by conservative methods. A posterior gastroenterostomy seemed to be the operation of choice with most surgeons. Spasm of the hypertrophied muscles due to local or reflex causes might be a factor in producing stenosis. Inflammatory changes might or might not be present.

(To be continued.)

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

BOARD OF MEDICAL EXAMINERS, STATE OF COLORADO.

Denver, January 3-7, 1911.

ANATOMY.

1. Describe the radius, including muscular and ligamentous attachments.
2. Describe the sternum, including muscular and ligamentous attachments.
3. Describe the elbow joint.
4. Describe the ankle joint.
5. Give the origin, insertion, and nerve supply of the following muscles: triceps, pyriformis, peroneus longus, levator ani, levator anguli scapulæ.
6. Name the supinators of the forearm and give the nerve supply of each.
7. Name the branches of the internal iliac artery.
8. Give the collateral circulation that would follow ligation of the common carotid.
9. Describe the lumbar plexus.
10. Describe the right kidney, including its relations. Alternate question: Where are the cortical centers of the face, arm, and forearm?

PHYSIOLOGY.

1. Discuss metabolism.
2. Discuss digestion.
3. Discuss elimination.
4. Discuss respiration.
5. Discuss circulation (blood and lymph).
6. Give a physical description of the blood, with functions of its component parts.
7. Define reflex arc, give examples of reflex action
8. Give in outline the sympathetic nervous system with functions.
9. Give distribution and function of cranial nerves.
10. Define hyperopia, myopia, and astigmia, giving general principles involved in their detection and correction.

CHEMISTRY.

1. What is indican, and what does it signify when found in the urine?
2. How would you determine the presence or absence of acetone in urine?
3. Define osmosis.
4. What are the chemical constituents of normal urine?
5. Give a concise description of a chemical examination of normal urine.
6. Name a chemical incompatibility, describing the reaction.
7. What chemical tests are used in the detection of occult blood?
8. Give a general definition of an ether.
9. Give the composition of water by volume and by weight.
10. What is a compound radical? Give examples, with the valence of each.

TOXICOLOGY.

1. From a medical standpoint define toxicology.
2. In the event you were called to a case with the following symptoms—drowsiness, headache, giddiness, stupor, delirium, convulsions, and paralysis, what would be your diagnosis?
3. What would be your treatment?
4. Give symptoms of poisoning by lead acetate.
5. Treatment and post-mortem appearance.
6. Give symptoms of poisoning by tartar emetic.
7. Treatment and post-mortem appearance
8. Give symptoms of poisoning by corrosive sublimate.
9. Treatment and post-mortem appearance.
10. Give difference in symptoms of poisoning by corrosive sublimate and those of arsenic.

PATHOLOGY.

1. Give the pathology of acute anterior poliomyelitis.
2. Describe the process of amyloid degeneration.
3. Describe the structure of sarcoma, giving the various types.
4. How would you make a Widal test?
5. How would you distinguish *B. coli communis* from *B. typhosus?*
6. Define (1) anaphylaxis, (2) tuberculin, (3) *Treponema pallidum*, (4) Wassermann reaction, (5) leukopenia.
7. Discuss uremia.
8. Describe the most common tumor found in bone
9. Describe the changes undergone in the brain after cerebral embolism.
10. Give microscopic appearances of a gumma.

SYMPTOMATOLOGY.

1. Describe, locate, and give causes of the different heart murmurs.
2. In what order and at what time do the teeth erupt in childhood?
3. Give symptoms of tuberculous hip-joint disease.
4. Give cause and symptoms of tuberculous hip-joint disease.
4. Give cause and symptoms of multiple neuritis.
5. Give symptoms of scurvy in children.
6. Give cause, prognosis, and symptoms of myocarditis.
7. Give symptoms of chronic appendicitis.
8. Describe your procedure in making a physical examination of the abdomen.
9. Differentiate between pyelitis and cystitis.
10. Give causes and symptoms of pulmonary edema.

OBSTETRICS.

1. Describe in detail your procedure after arrival at the lying-in chamber when the patient is (*a*) in the first stage of labor, (*b*) in the second stage, (*c*) and the third stage.
2. Describe the toxemias of pregnancy and tell what you would do to prevent or relieve same.
3. What is "morning sickness"? Give causes, duration, and treatment.
4. What are the indications for the use of the obstetrical forceps? Describe their application.
5. Give directions for the care of a woman after delivery—(*a*) normal, (*b*) instrumental.
6. When should a lacerated perineum be repaired, and give technique
7. What means would you employ to prevent laceration of the perineum when the head is well down on the perineum and labor pains are strong?
8. How would you treat a case of ophthalmia neonatorum.
9. Give symptoms of pregnancy and their relative importance.
10. Give method of procedure in case of retained secundines in four month abortion.

SURGERY.

1. Give the causes of arteritis and describe the symptoms and complications.
2. What are the symptoms and causes of lymphadenitis?
3. Give the symptoms of a tuberculous abscess.
4. Discuss sarcoma of the kidney.
5. Give the symptoms and causes of acute osteomyelitis.
6. Give some of the complications and consequences of fractures.
7. Give the symptoms of fracture of the surgical neck of the humerus.
8. Give the symptoms of tuberculous arthritis of the elbow-joint.
9. Give the symptoms of dislocation of the head of the femur on the dorsum of the ilium and what per cent. of hip dislocations does this form comprise?
10. Give the symptoms of strangulated hernia.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

BOARD OF MEDICAL EXAMINERS, STATE OF COLORADO.

Denver, January 3-7, 1911

ANATOMY.

1. See Cunningham's "Anatomy" (1909), pages 108, 279, and 284; or Gray's "Anatomy" (1910), page 190.
2. See Cunningham's "Anatomy" (1909), pages 941 and 271; or Gray's "Anatomy" (1910), page 157.
3. See Cunningham's "Anatomy" (1909), page 279; or Gray's "Anatomy" (1910), page 306.
4. See Cunningham's "Anatomy" (1909), page 306; or Grey's "Anatomy" (1910), page 342.
5. TRICEPS. *Origin:* Below glenoid fossa or scapula, outer and posterior surface of humerus below greater tuberosity, and from posterior surface of humerus below musculospiral groove. *Insertion:* Olecranon surface of ulna. *Nerve supply:* Musculospiral.

PYRIFORMIS. *Origin:* Margin of anterior sacral foramina and great sacrosciatic notch of ilium. *Insertion.* Upper border of great trochanter of femur. *Nerve supply:* Sacral plexus.

PERONEUS LONGUS. *Origin:* Upper two-thirds of outer

surface of fibula, and external condyle of tibia. *Insertion:* Internal cuneiform and first metatarsal bone. *Nerve supply:* Peroneal.

Levator ani. *Origin:* Back of pubic bone, spine of ischium, and pelvic fascia. *Insertion:* Central point of perineum, external sphincter ani, sides of lower part of sacrum and of coccyx. *Nerve supply:* Pudic, and 3rd and 4th sacral.

Levator anguli scapulæ. *Origin:* Posterior tubercles of transverse processes of upper four cervical vertebræ. *Insertion:* Superior angle of scapula. *Nerve supply:* Anterior divisions of 3rd and 4th cervical.

6.

SUPINATORS OF FOREARM.	NERVE SUPPLY.
Supinator brevis.	Dorsal interosseous.
Biceps.	Musculocutaneous.
Supinator longus.	Musculospiral.

7. *Branches of internal iliac:* Superior vesical, middle vesical, inferior vesical, middle hemorrhoidal, obdurator, internal pudic, sciatic, ilio-lumbar, lateral sacral, gluteal; and uterine and vaginal in the female.

8. The collateral circulation, after ligation of the common carotid, is through (1) the internal carotid and vertebral of one side with those of the other, through the circle of Willis; (2) superior thyroid with inferior thyroid; (3) deep cervical of superior intercostal with princeps cervicis of occipital; (4) superior thyroid, lingual, facial, occipital, and temporal branches of external carotid, with corresonding arteries of the other side.

9. See Cunningham's "Anatomy" (1909), page 641; or Gray's "Anatomy" (1910), page 104.

10. See Cunningham's "Anatomy" (1909), pages 1130 and 1133; or Gray's "Anatomy" (1910), pages 1345 and 1356.

The *motor areas* are located and arranged on the cerebral cortex, immediately in front of the fissure of Rolando. At the upper part of the convolutions in front of this fissure are areas connected with the movements of the lower extremities; then from above downward are located the centers for movements of the shoulders, arms, wrists, fingers, face, lips, tongue, and larynx and pharynx.

PHYSIOLOGY.

1. *Metabolism* is the entire series of changes that occur in a cell or organism during the processes of nutrition. It is of two kinds: (1) Assimilative or constructive (anabolism) and (2) destructive (katabolism).

2. *Digestion* is the process by which food is converted into material suitable for absorption and assimilation.

The different stages of digestion are: (1) *In the mouth*, where the food is crushed, mixed with saliva, and reduced to a pulp; a certain amount of starch converted into maltose and rendered slightly alkaline. Fats and proteids are unaltered. (2) *In the stomach*, where the contents are rendered acid, conversion of starch into sugar ceases, connective tissue of fats is dissolved and fats are set free. Proteids are dissolved and peptones formed. The albuminous foods are dissolved for the most part, and a grumous mixture of peptones, liquid fats, and starches is formed, which is termed chyme, and is gradually passed through the pylorus into the intestine. (3) *In the intestine*, where the chyme mixes with the bile, pancreatic and intestinal juices, becomes alkaline, conversion of starch into sugar recommences, emulsifying of fat begins, and the undissolved proteids are converted into peptones. The diffusible peptones and salts enter the portal vein, the fat in a fine state of division entering the lacteals. In the large intestine the liquid chyme becomes more and more solid, is rendered acid by fermentative changes, and acquires the odor of feces. (From Ashby's *Notes on Physiology.*)

The different fluids essential to the same are: Saliva, gastric juice, pancreatic juice, succus entericus, and bile.

The *source* of the saliva is the salivary glands; of the gastric juice, the glands of the stomach; of the pancreatic juice, the pancreas; of the bile, the liver; and of the succus entericus, the glands of the small intestine.

The functions of the saliva are: (1) To moisten the mouth, (2) to assist in the solution of the soluble portions of the food, and thus (3) to administer to the sense of taste, (4) to lubricate the bolus of food, and thus (5) to facilitate the acts of mastication and deglutition, and (6) to change starches into dextrin and sugar.

The functions of the gastric juice are: (1) To change proteids into proteoses and peptones, and (2) to curdle the casein of milk.

The functions of the pancreatic juice are: (1) To change proteids into proteoses and peptones, and afterwards decompose them into leucin and tyrosin; (2) to convert starch into maltose; (3) to emulsify and saponify fats; and (4) to cause milk to curdle.

The functions of the bile are: (1) To assist in the emulsification and saponification of fats; (2) to aid in the absorption of fats; (3) to stimulate the cells of the intestine to increased secretory activity, and so promote peristalsis, and at the same time tend to keep the feces moist; (4) to eliminate waste products of metabolism, such as lecithin and cholesterin; (5) it has a slight action in converting starch into sugar; (6) it neutralizes the acid chyme from the stomach and thus inhibits peptic digestion; (7) it has a very feeble antiseptic action.

The functions of the succus entericus are: The secretion of enterokinase, secretin, and erepsin, which assist the pancreatic juice in digestion.

3. *Elimination* is the process by which waste material is removed from the body; it takes place by the breath, sweat, urine, and feces.

4. *Respiration* is the process by which an interchange of gases takes place in the lungs; so that oxygen is introduced and carried to the tissues, and carbon dioxide is expelled. See Gray's "Anatomy" (1910), page 423.

The changes produced in the *air* by respiration are:

	INSPIRED AIR.	EXPIRED AIR.
Oxygen	21 per cent.	16.6 per cent.
Nitrogen	79 per cent.	79 per cent.
Carbon dioxide	0.04 per cent.	4.4 per cent.
Other gases	Rare.	Often present.
Watery vapor	Variable.	Saturated.
Temperature	Variable.	That of the body.
Volume	Varies.	Diminished.
Bacteria	Always present.	None.
Dust	Always present.	None.

5. See Gray's "Anatomy" (1910), page 569.

The lymphatic circulation is, strictly speaking, not a circulation at all; since the lymph flows only in one direction, namely, toward the heart. The lymph capillaries take up any excess of the blood plasma which is not required for the nutrition of the tissues. These capillaries consist of a single layer of epithelium, and empty themselves into vessels very like the veins. The lymph vessels are well provided with valves, which are so closely approximated as to give the vessels a beaded appearance. All the lymphatic vessels, except those of the right upper half of the body, empty into the thoracic duct, which terminates in the left subclavian vein, where the left internal jugular vein also enters. Those from the right upper half of the body discharge into the right lymphatic duct, which, in turn, empties into the right subclavian vein at its junction with the right internal jugular vein.

6. The *physical properties of blood:* Fluid, somewhat viscid, red, specific gravity from 1055 to 1062, alkaline reaction, saltish taste, characteristic odor, variable temperature (average about 100° F.).

The *constituents of the blood* are plasma and corpuscles. The *plasma* consists of water and solids (proteids, extractives, and inorganic salts). The *red corpuscles* consist of water and solids (hemoglobin, proteids, fat, and inorganic salts). The *white corpuscles* consist of water and solids (protein, leuconuclein, lecithin, histon, etc.).

The *function of the red cells* is to carry oxygen from the lungs to the tissues.

Functions of white cells: (1) To serve as a protection to the body from the incursions of pathogenic microorganisms; (2) they take some part in the process of the coagulation of the blood; (3) they aid in the absorption of fats and peptones from the intestine, and (4) they help to maintain the proper proteid content of the blood plasma.

There are also *platelets*, whose function is not determined; it is possible that they take some part in the coagulation of the blood.

Plasm conveys nutriment to the tissues; it holds in solution the carbon dioxide and water which it receives from the tissues, and takes them to be eliminated by the lungs, kidneys, and skin; it also holds in solution urea and other nitrogenous substances that are taken to and excreted by the liver and kidneys.

7. *Reflex actions* are involuntary or unconscious movements due to suitable stimuli. They depend upon the integrity of the *reflex arc*, which is a complex made up of: (1) A surface capable of receiving an impression; (2) an afferent nerve; (3) a nerve cell capable of receiving and

also of sending out impulses; (4) an efferent nerve, and (5) a surface capable of responding in some way to the impulse conveyed by the efferent nerve. *Example:* The patellar reflex consists of a contraction of the extensor muscles of the leg and a movement of the foot forward when the ligamentum patellæ is struck; the quadriceps extensor must first be slightly stretched by putting one knee over the other. Its integrity depends upon a healthy condition of the entire reflex arc, consisting of tendon, afferent or sensory nerve, posterior roots, and anterior horn of the spinal cord, the efferent or motor nerve, and the muscle itself.

8. See Cunningham's "Anatomy" (1909), page 704; or Gray's "Anatomy" (1910), page 1066.

Functions of the sympathetic nervous system: "It may safely be said that the sympathetic system has, to a great extent, a controlling influence over the secretion of most of the glands, the lacrymal, the salivary, the sweat glands, the glands of the stomach and intestines, the liver, the kidney, etc.; that it presides over the circulation by regulating the caliber of the blood-vessels and the action of the heart; that it influences respiration; and, finally, that all involuntary muscles, those of the digestive apparatus, of the genitourinary system, of the hair follicles (pilomotor nerves), are under its control to such an extent that, for instance, in certain mammalians the bladder still continues to fulfil its function for weeks after all the cerebrospinal motor nerves leading to it have been severed. In short, we find that all vegetative life of the organism is, to a greater or less extent, under the control of the sympathetic system. Therefore it may properly be called the vegetative nerve system *par excellence*."—(*Reference Handbook of the Medical Sciences.*)

9. See Cunningham's "Anatomy" (1909), pages 674, etc.; or Gray's "Anatomy" (1910), pages 976, etc.

10. (1) *Hyperopia* is the condition in which the eyeball is shorter than normal, or the cornea or lens unduly curved, and so parallel rays of light are focused behind the retina instead of on it. It should be treated by a convex lens whose principal focus is at the far point of the hyperopic eye. (2) *Myopia* is the condition in which the eyeball is too long, and so parallel rays of light are focused in front of the retina. It should be treated by the weakest concave lens which gives clear distance vision, and by reducing the amount of near work. (3) *Astigmatism* is the condition in which the different meridians of the eye refract the rays of light differently. It is treated by a cylindrical lens properly adjusted; this should be worn constantly.

CHEMISTRY.

1. *Indican* is indoxyl potassium sulphate; it is found (in excess) in the urine in hypochlorhydria; in hyperchlorhydria of gastric ulcer; in conditions in which there is diminished peristalsis of the small intestines, as in ileus and peritonitis, not in simple constipation; also in conditions in which putrefactive changes occur in the body elsewhere than in the intestine, as in empyema, putrid bronchitis, gangrene of the lungs, etc.—(From Witthaus' *Essentials of Chemistry.*)

2. *Test for acetone:* Add to the urine a few drops of a freshly prepared solution of sodium nitroprusside, and then solution of potassium hydroxide; if acetone is present the liquid is colored ruby-red, and on supersaturation with acetic acid becomes purple.

3. *Osmosis* is the process by which certain fluids and substances in solution pass through a membrane or other porous substance.

4. *Normal urine* consists of: Water, 95 per cent.; solids, 5 per cent. The latter are: Urea, 2.8 per cent.; uric acid, 0.06 per cent.; hippuric acid, 0.03 per cent.; creatinin, 0.06 per cent.; extractives, 0.8 per cent.; sodium chloride, 0.8 per cent.; phosphates, 0.2 per cent.; sulphates, 0.1 per cent.; oxides of calcium, magnesium, sodium, and potassium, 0.1 per cent.

5. See French's "Practice of Medicine" (1910), page 1233.

6. Solutions of silver nitrate and sodium chloride would represent a "chemical incompatibility." The reaction is:

$$AgNO_3 + NaCl = AgCl + NaNO_3.$$

7. Chemical tests used in the detection of occult blood are: The aloin test, and the guaiac test. See French's "Practice of Medicine" (1910), page 1231.

8. An ether is the oxide of a hydrocarbon radical, produced by the action of an acid on an alcohol.

9. Composition of water. *By volume:* Two parts of hydrogen to one part of oxygen. *By weight:* Two parts of hydrogen to sixteen parts of oxygen.

10. A compound radical is a group of atoms behaving in chemical reactions as a single atom. *Example:* NH_4 with a valence of one; C_2H_5 with a valence of one; CO with a valence of two; CH with a valence of three.

TOXICOLOGY.

1. *Toxicology* is that branch of medical science which appertains to poisons; it includes their character, origin, actions, symptoms produced, antidotes, treatment, and detection.

2 and 3. Probably atropine poisoning. *Treatment:* "Lavage of the stomach; morphine may be given cautiously during the period of violent excitement. Maintain respiration; strong coffee by the mouth or rectum is beneficial. Pilocarpine may be given, in not too large doses, to stimulate the secretion of saliva."—from Witthaus' *Essentials of Chemistry.*

4 and 5. The *symptoms of acute lead poisoning* are: "Metallic taste; dryness of the throat; thirst; severe colicky abdominal pains, referred particularly to the umbilical region, and relieved by pressure; pulse very feeble and slow; great prostration; constipation; urine scanty and red; violent cramps; paralysis of the lower extremities; convulsions, and tetanic spasms."

The *treatment* consists in administering "magnesium sulphate, which brings about the formation of the insoluble lead sulphate, while the purgative action of the magnesia is also useful. It should be preceded by an emetic, or by the use of the stomach tube."

Post-mortem appearances: Not always characteristic; mucous membrane of stomach may be red or gray; there is blue line on the gums; the colon may be constricted.

6 and 7. *Symptoms of poisoning by tartar emetic:* "These are seldom delayed more than half an hour. Nausea, violent and continual vomiting, burning pain in stomach and bowels, with an acrid, burning sensation in the throat, are usually the first symptoms. Then purging, intense thirst, feeble, rapid pulse, cramps in legs, and general lowering of the temperature, with great prostration, follow. The coldness extends even to the internal organs. The bowels become tympanitic. The spinal centers are greatly depressed. The urine is generally increased, but sometimes diminished or suppressed, and may be bloody and passed with difficulty and pain. Delirium and convulsions may precede death, or the patient may sink into coma, or die from exhaustion."—(Riley's *Toxicology.*)

Treatment.—Wash out the stomach or assist vomiting by abundant warm demulcent drinks. Then give tannin in some form. As the poison is quite rapidly absorbed, promptness is important. It is well in washing out the stomach to use some form of tannin solution, as tea, infusion of oak bark, etc., if available. Borax in milk (5 per cent. solution) has been used with much apparent success. Then sustain the heart with strychnia hypodermically, digitalis, or strophanthus. If nausea is persistent opiates may be necessary.

Post-mortem appearances.—The mucous membrane of the throat, stomach and bowels is usually red, softened, and shows general signs of severe irritation or even inflammation. In the stomach the mucous membrane is apt to be covered with small extravasations of blood and occasionally pustular eruptions. The mucous membrane of the bowels is frequently covered with a dark yellowish, viscid secretion. The brain and lungs are generally congested. In chronic cases the large intestine is also inflamed and the liver enlarged and softened. (Riley's *Toxicology.*)

8 and 9. *Symptoms of poisoning by corrosive sublimate:* A nauseous, metallic taste is experienced during the act of swallowing. Within a few moments this is followed by an intense, burning pain in the mouth, throat, and stomach. The mouth and tongue are whitened and shriveled. There are vomitings of a white material containing shreds of mucous membrane, and tinged with blood, and bloody stools. Salivation occurs if life be sufficiently prolonged. Death sometimes occurs early from collapse, accompanied by convulsions, or in deep coma; but in most fatal cases life is prolonged for from three to six days.

Treatment: The antidote is white of egg, but too much must not be given at one time; this should be followed by an emetic.

Post-mortem appearance: The salivary glands are enlarged. The tongue, mouth, esophagus and mucous membrane are usually shriveled and grayish white in color, though sometimes they are reddened and intensely inflamed. The intestines are usually highly congested and the urinary bladder contracted and empty. (Witthaus' *Essentials of Chemistry and Toxicology.*)

10.

POISONING BY ARSENIC.	POISONING BY MERCURY.
(1) The symptoms rarely begin within 20 minutes.	(1) The symptoms begin almost immediately.
(2) Pain is usually limited to the stomach and throat.	(2) Pain is also severe in the mouth.
(3) The taste is very faint, sweetish and metallic. Usually none.	(3) The taste is intensely metallic, and nauseous.
(4) The mouth and tongue are normal.	(4) The mouth and tongue are whitened.
(5) The urine contains arsenic.	(5) The urine contains mercury.

(Witthaus' *Essentials of Chemistry.*)

PATHOLOGY.

1. See French's "Practice of Medicine" (1910), page 1068; or Osler's "Practice of Medicine" (1909), page 915.
2. See French "Practice of Medicine" (1910), page 34.
3. See Rose and Carless' "Surgery" (1908), page 188; or Da Costa's "Surgery" (1908), pages 316 and 320.

4. The Widal serum reaction "depends upon the fact that serum from the blood of one ill with typhoid fever, mixed with a recent culture, will cause the typhoid bacilli to lose their motility and gather in groups, the whole called 'clumping.' Three drops of blood are taken from the well-washed aseptic finger tip or lobe of the ear, and each lies by itself on a sterile slide, passed through a flame and cooled just before use; this slide may be wrapped in cotton and transported for examination at the laboratory. Here one drop is mixed with a large drop of sterile water, to redissolve it. A drop from the summit of this is then mixed with six drops of fresh broth culture of the bacillus (not over twenty-four hours old) on a sterile slide. From this a small drop of mingled culture and blood is placed in the middle of a sterile cover-glass, and this is inverted over a sterile hollow-ground slide and examined. . . . A positive reaction is obtained when all the bacilli present gather in one or two masses or clumps, and cease their rapid movement inside of twenty minutes." (From Thayer's *Pathology.*)

5. The cultural and microscopical points of difference between the *Bacillus coli communis* and the *Bacillus typhosus* (of Eberth) are:

"(1) The motility of the colon bacillus is, as a rule, not very pronounced, sometimes absent; that of the typhoid bacillus is usually very active.

"(2) On gelatine plates the colon bacillus develops more rapidly and luxuriantly than the typhoid bacillus, and on potato it grows more abundantly, being almost always visible.

"(3) The colon bacillus coagulates milk with acid reaction within twenty-four to forty-eight hours; the typhoid bacillus does not coagulate milk.

"(4) The colon bacillus causes fermentation with production of gas in media containing sugar; the typhoid bacillus does not.

"(5) In nutrient agar or gelatine containing lactose and litmus tincture and of a slightly alkaline reaction the color of the colonies of colon bacillus is pink and the surrounding medium red; while the colonies of typhoid bacillus are blue and there is little or no reddening of the medium.

"(6) The colon bacillus produces indol in cultures of bouillon or peptone; the typhoid bacillus does not.

"(7) When a twenty-four-hour-old bouillon culture of the colon bacillus is mixed with the blood or serum of a patient suffering from genuine typhoid fever, in a dilution of one to ten or more, after the first week of the disease, the Widal reaction is negative; cultures of the typhoid bacillus treated in the same manner and examined in the hanging drop give the characteristic agglutination and clumping of the bacilli." (*Reference Handbook of the Medical Sciences.*)

6. *Anaphylaxis* is increased susceptibility to infection or to the action of any foreign protein introduced into the body, following a primary infection; it is the opposite of immunity.

Tuberculin is a preparation made from cultures of the tubercle bacillus, employed as a means of diagnosis and in the treatment, by active immunization, of tuberculosis.

Treponema pallidum is the pathogenic parasite of syphilis. See French's "Practice of Medicine" (1910), page 426.

Wassermann reaction is a diagnostic test for syphilis based upon the theory of complement fixation.

Leukopenia is a condition in which the number of leucocytes in the circulating blood is reduced below the normal for the individual. (From Stedman's *Medical Dictionary.*)

7. See French's "Practice of Medicine" (1910), page 905; or Osler's "Practice of Medicine" (1909), page 683.

8. Osteosarcoma. See Rose and Carless' "Surgery" (1908), page 602.

9. See French's "Practice of Medicine" (1910), page 1115; or Osler's "Practice of Medicine" (1909), page 977.

8. *Physical examination of the abdomen:* "All clinical methods are applicable to this region. The customary prior cathartic removes misleading fecal masses, but accomplishes little more, and may produce a flatulent distention and troublesome peristaltic activity.

"The head and shoulders, particularly the former, should be high, the feet firmly placed and the patient in an easy and unconstrained dorsal posture. To relax the walls the knees may be drawn up, but often better relaxation may be had with the legs extended or but slightly flexed. The breathing should be easy and natural, with the mouth open, and the patient's attention should be diverted by conversation and inquiry. The hands should be warm, the light should be adequate, its source behind the patient, and no clothing or other covering embarrass the examiner. The flat of the palm and fingers, not the tips, should be used, tender areas should not be immediately approached, nor does the discovery of one justify repeated and purposeless punching and poking. In palpating movable organs or growths respiratory movement should be met directly by the tips of the fingers at right angles to the free margin, the hand being firmly but gradually depressed in deep expiration and allowed to rise laggingly and shift slightly upward to meet the descending border in inspiration. If the hand moves the organ or growth under examination, the opposite palpating hand should be almost motionless as the other brings the organ or tumor to it. After tolerance is established, the finger tips may be used to determine consistence and outline. The deep or superficial character of any pain or tenderness developed by examination and its precise localization or extent of diffusion should be accurately determined. Malingering or hysterical patients can often be misled or diverted by conversation, by attracting their attention to some special region which is being explored by one hand while the supposed tender point is palpated by the other or by misleading and positive statements as to the effect of pressure, forced respiration, etc., upon the spurious symptoms. In some cases nothing less than general anesthesia suffices. The dorsal posture is the best for general purposes, but the lateral is of value in palpation of the spleen or kidneys or for the purpose of "spilling" the intestinal contents of a large-bellied person to render more accessible the lateral region under examination. The patient may with advantage be placed upon the hands and knees or in the knee-chest position to bring a growth forward against a thin and relaxed abdominal wall. Finally, all portions of the abdomen should be thoroughly examined, not forgetting the hernial openings. The full hot bath is a most useful adjunct." (Greene's *Medical Diagnosis.*)

8. OPHTHALMIA NEONATORUM. *Prophylaxis:* Whenever there is a possibility of infection, or in every case, wash the eyelids of the newborn child with clean warm water, and drop on the cornea of each eye one drop of a 1 or 2 per cent. solution of nitrate of silver immediately after birth.

Treatment: Wash the eyes carefully every half hour with a saturated solution of boric acid; pus must not be allowed to accumulate. Two drops of a 2 per cent. solution of nitrate of silver must also be dropped on to the cornea every night and morning. The eyes must be covered with a light, cold, wet compress. The patient must be isolated, and all cloths and compresses used must be burnt.

California.—By recent changes in the law the State board may issue a certificate to any person who has practised a special branch of medicine and surgery for not less than thirty-five years, if he give satisfactory demonstration of his qualifications. It is also provided that any applicant for a certificate obtaining 75 per cent. each in seven subjects shall be subsequently re-examined in those subjects only in which he failed. Every person is guilty of a misdemeanor who commits fraud in connection with a certificate or diploma or assumes the title of M.D. or doctor without right. Any surgeon honorably discharged from the medical department of the United States Army or Navy, regular or volunteer, is authorized to practise medicine on payment of a $50 fee.

Pennsylvania.—The new one-board bill goes into effect on January 1, 1912.

South Carolina.—There is a bill before the Senate requiring members of the State Board of Medical Examiners to pass "a strict examination before the faculty of the Medical College of the State of South Carolina as to their qualifications for the position."

Metatarsalgia.—W. Truslow makes a plea for more careful examination of feet that are painful and less empirical dosage for "rheumatism," for the treatment of a mechanical condition by mechanical means, and, in general, professional cooperation in the warfare on deforming shoes, even to the personal use by physicians of correct shoes.—*Long Island Medical Journal.*

Medical Items.

Importance of Analysis of Mother's Milk in Some Cases of Dyspepsia in Nurslings.—Barbier thinks that it is especially important in cases of dyspepsia in infants that are nursed to have an exact examination of the milk. There are considerable variations at different times of the day, and according to the food taken by the mother. The milk having the least casein and butter is obtained in the morning, while the richest is obtained about 4 in the afternoon. If we give the mother a diet rich in albuminoids we get a milk that is rich in casein, and in which the butter is increased. If she takes many carbohydrates we get little casein and much butter. We can thus see how a knowledge of the analysis of the milk may aid us in arranging the hours of nursing, placing the nursings farther apart, or may assist us in modifying the food of the mother so as to get more or less casein or butter than she is producing.—*Journal de Médecine de Paris.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended July 21, 1911:

THE PREVENTION OF EPIDEMICS OF INFANTILE PARALYSIS.*

By M. ALLEN STARR, M.D., LL.D.,

NEW YORK.

PROFESSOR OF NEUROLOGY, COLLEGE OF PHYSICIANS AND SURGEONS; MEDICAL DEPARTMENT OF COLUMBIA UNIVERSITY.

THE facts which I present to you to-night, while familiar to neurologists, are not sufficiently well known to the general practitioner, and hence, in this audience, I venture to put them before you without any claim to originality.

It has been known for some time that infantile paralysis is an acute infectious disease, like measles or scarlet fever—a fact which has been suspected ever since the occurrence of the first epidemics, the first important one in this country being that reported by Caverley of Rutland in 1895. Ever since that time the possibility of the epidemic extension of infantile paralysis has been admitted, and in 1908 I was able to collect the records of forty-six epidemics which had occurred up to that time,[1] and I have knowledge of eleven more epidemics that have been observed since. It is well known that these epidemics are increasing rapidly, that the disease is cropping out in different parts of this country, and is affecting many children in any town or village where it appears.

The prevalence of the disease in Sweden and Norway, the most extensive epidemics on record having occurred there, has led to the belief that it has been disseminated through this country by the ingress of Scandinavian immigrants, but as yet this is merely an hypothesis. The more definite knowledge regarding its nature and its mode of propagation is due to the investigations by Flexner and his assistants at the Rockefeller Institute. The disease is due to an infectious agent not as yet isolated, but present in the cerebrospinal fluid and probably in the blood of those persons who are affected by the disease. The infection can be communicated from one individual to another, and it is quite certain that the infectious material exists in the secretions of the nose and throat.[2] It is probable that it is through the inhalation of infectious particles which lodge in the mucous membranes of the nose and throat that the infection enters the system.

If these facts be granted, certain conclusions with regard to the means necessary for the prevention of the disease naturally follow. In the first place, it is essential that any patient suffering from the disease should be isolated from contact with others at the earliest possible moment, and should be quarantined as is a patient suffering from scarlet fever, from diphtheria, etc., so that the rest of the family or the neighbors shall not be exposed to the disease. An upper room in the house should be chosen, sunny and airy; a nurse put in exclusive charge, and supplies carried by another, and all dishes and clothing disinfected. This quarantine should be kept up for at least a month. Secondly, the more or less constant disinfection of the nasal and buccal mucous membranes should be maintained in the person suffering from the disease by means of sprays and gargles of an antiseptic nature. Dobell's solution or a saturated solution of boric acid is adequate. Thirdly, all those who are exposed to the disease should constantly use sprays and gargles which will keep the mucous membranes of the nose and throat in a condition less liable to receive the infectious material. The spraying with a saturated solution of boric acid or with Dobell's solution is distinctly indicated as a prophylactic measure. It should be used by healthy children every time they go out of doors in the city, and also when they come in. And if a case of the disease has developed in a child at school the other scholars should be made to use these sprays and should be dosed at once with urotropin. The contagious material persists for several months in the nasal secretion of the person who had the disease, hence constant disinfection should be kept up for three months at least.

The most recent investigations by Flexner have demonstrated the fact that urotropin given internally to monkeys who are subsequently exposed to the infection of this disease lessens the liability of their contracting the disease, and the administration of urotropin immediately after the injection of the poison of the disease in monkeys tends to mitigate the severity and sometimes to prevent the occurrence of the symptoms. For these reasons it seems evident that the early use of urotropin in cases where anterior poliomyelitis is suspected is decidedly indicated, and that the early treatment of patients with this remedy is imperative, not only as a method of cure for the individual, but also as a method for the prevention of the extension of the disease to others. It is this latter fact particularly which has led me to draw the attention of this audience to the possibility of prophylaxis in infantile paralysis, as I regard the discovery as one of immense importance in the possible prevention of epidemics of this disease which at present threaten the community.

But if these remedies are to be applied, it is evident that the disease must be recognized in its earliest stage. The early diagnosis of anterior poliomyelitis is extremely difficult. The cases come exclusively into the hands of the general practitioner and are rarely seen by the specialist until the disease is fully developed. For this reason these measures of prophylaxis must be exercised wholly by the family physician, and hence any

*Read before the Neurological Section of the Academy of Medicine, April 11, 1911.

facts leading to an early diagnosis should be in his possession.

The study of the cases appearing in epidemic form has demonstrated that the disease is by no means uniform in its mode of onset. Many varieties have been described, depending upon the part of the nervous system which happens to be attacked by the poison. Thus, if the infection attacks the brain, cerebral symptoms predominate; if it attacks the cerebral axis, including the pons and medulla, symptoms of the nature of bulbar paralysis appear early, and cranial nerve symptoms are the first observed; if the disease affects the spinal cord, as is most common, it may be the upper or the lower segments of the cord that are invaded, or a diffuse process may affect the entire nervous system. Hence it is evident that the variety of symptoms possible is very great.

There are great varieties in the severity of the onset, which have led to different types being classified. We may have the very slight affection which manifests itself even in the extreme degree by a moderate febrile movement and a mere general enfeeblement and temporary weakness of certain muscles, and this is described as the abortive type. From this light affection we may have every variety of invasion up to the point of a total paralysis of both arms, both legs, and of the facial muscles, with death occurring on the second or third day from respiratory paralysis. It is thus evident that the degree of the symptoms in any one case may be extremely variable and that the early diagnosis is therefore extremely difficult.

The earliest symptoms in almost all the cases resemble those of any acute infection. Hence for several days it may be a question in the mind of the physician whether the patient is about to develop measles, scarlet fever, or typhoid fever, the latter being the disease which is most commonly diagnosticated.

On the first day there is a fever, temperature of 101° or 102°, possibly 103°, with rapid pulse, occasional sighing, and irregular respiration and yawning, chilly sensations, general pain in the limbs and in the head, frequently in the back, and an irritation of the digestive organs shown by nausea, vomiting, or diarrhea, the latter being more frequent than vomiting. On the second day these symptoms usually increase in intensity, the headache becomes more marked, and the patient is restless and dull, sometimes somnolent, and has more or less the appearance of a patient in beginning typhoid, face being suffused, eyes congested, body generally hypersensitive, and there being occasionally rigidity of the neck and of the back. Very often profuse sweating is observed. Sometimes a diffuse rash like erythema is seen. On the third day the fever reaches its maximum in the majority of instances, not often rising above 103°. The pulse is rapid, respiration may be irregular, headache intense, general pains more severe, digestion more impaired, urine high colored, of high specific gravity, and possibly containing traces of albumin. At this time it is not uncommon to find some difficulty in passing the water, which may have to be drawn, and occasionally there is also a loss of control of the rectum. As a rule the tendon reflexes are diminished and sometimes are lost. Kernig's sign may be present. It is on the third day, as a rule, that some evidence of paralysis is discovered in some muscle or group of muscles in the body. This may be preceded by an unusual coldness of the extremity for some hours, due to an early vasomotor paralysis. There may be merely a strabismus or a facial palsy, or there may be a paralysis of one or more of the extremities. After the paralysis develops there is, of course, no doubt with regard to the diagnosis, and then the case will run its course so that the maximum of intensity of the symptoms is reached on the fourth or fifth day. In the extremely severe cases death has usually occurred on the fifth or sixth day from respiratory paralysis. In the vast majority of the cases the general symptoms subside, but the paralysis remains at its maximum intensity for at least two weeks, when the subsequent improvement that is customary begins.

It was already stated that during the first three days of the onset of the disease it is almost impossible to make an absolute diagnosis, but it seems to me that in view of the facts already stated with regard to the communication of the disease by the nasal secretions, and the possibility of aborting the attack by the use of urotropin, that in any case where a child is attacked with indefinite febrile symptoms, such as are here described, it is imperative upon the physician, without waiting for a positive diagnosis, to disinfect the nose and throat frequently and to administer urotropin from the very onset of the symptoms. The dose should be two grains of urotropin every six hours for a child of two or three years of age; a dose of three grains for a child six to ten years of age, and a dose of five grains for an adult. It is possible that if, in the early stage beginning with fever, this remedy is used, the subsequent development of a severe attack of anterior poliomyelitis may be avoided, and the extension of the disease to others may be prevented. It is for the purpose of making this suggestion and urging it upon the general practitioner that this brief summary of facts, familiar to the neurologist, is here presented.

An examination of the blood appears to be an important aid to diagnosis during the early stage of the disease. On the second day of onset an increase in the leucocytes has been observed, and in some cases on the third day a distinct leucopenia has been noticed, with an increase of eosinophile corpuscles and of lymphocytes. In a case recently reported by Dr. Frissell[3] the examination on the third day of the disease showed: red cells, 5,020,000; hemoglobin, 92 per cent.; leucocytes, 12,000; small lymphocytes, 30.2 per cent.; large lymphocytes, 4.8 per cent.; polymorphonuclears, 64.6 per cent.; eosinophiles, 0.2 per cent; basophiles, 0.2 per cent; and two days later the small lymphocytes had increased to 34 per cent., while the polymorphonuclears had fallen to 59 per cent. In another patient under my observation on the fourth day of the disease the red cells were 5,003,000; the leucocytes, 14,500; small lymphocytes, 32 per cent.; large lymphocytes, 5 per cent.; polymorphonuclears, 68 per cent.; eosinophiles, 0.4 per cent. The blood examination simply indicates, therefore, an infection which may be of various kinds, and there is nothing characteristic of this disease to be gathered from the blood count.

The examination of the cerebrospinal fluid, as obtained by lumbar puncture, is more important. From the many examinations by Flexner and his assistants of the cerebrospinal fluid from monkeys, certain definite changes may be said to have been found constantly, and in several recent cases where the cerebrospinal fluid has been examined on the

third or fourth day in infants these changes have been found as well. As a rule the amount of cerebrospinal fluid is slightly increased, so that on puncture the flow is a little more free than in the normal state. The fluid may be quite clear or there may be a slight opalescence, usually the latter. On centrifugalization the fluid yields a sediment containing a considerable number of small and large lymphocytes and a few polynuclear leucocytes. This increase of lymphocytes, or white corpuscles, occurs also in tubercular meningitis, but there is usually no difficulty in distinguishing this disease from anterior poliomyelitis. Flexner has shown that the clear fluid gives a protein reaction when tested by Noguchi's butyric acid test. This also is present in monkeys and is not present in tubercular meningitis. In the recent case reported by Dr. Frissell this change in the cerebrospinal fluid was detected on the fifth day of the disease and was present before paralysis developed, and led Flexner to predict the onset of paralysis, which occurred the next day. It is evident, therefore, that the examination must be conducted with great care, as it should be done under the most aseptic precautions; that the tubes in which the fluid is collected should be absolutely sterile; that it is not necessary to obtain more than 5 or 6 c.c. of the fluid; that the examination can only be entrusted to those who are most expert in the detection of these changes which have been described. While it is easy, therefore, for us who are in close communication with the laboratories of the city and of the Rockefeller Institute to have such examinations made, it is by no means easy for the general practitioner away from the chief medical centers to resort to this method of investigation. As the disease progresses and passes from the active stage into the stage of recovery the opalescence of the cerebrospinal fluid diminishes, the reaction for protein diminishes, and the leucocytes remain at about the same percentage of excess for several days. I believe the case recently reported by Dr. Frissell is the first one in which the diagnosis of lumbar puncture has been made before paralysis appeared, and therefore it deserves especial attention.[3]

If, therefore, the diagnosis of infantile paralysis can be made on the second or third day of the disease, and urotropin given promptly, we may mitigate the severity of the symptoms. And if the precautions here suggested are taken it is possible that the spread of the disease may be prevented.

EPILEPSY AND THE EPILEPTIC TEMPERAMENT.*

By EDWARD LIVINGSTON HUNT, M.D.,

NEW YORK.

INSTRUCTOR IN NEUROLOGY, COLUMBIA UNIVERSITY; CONSULTING NEUROLOGIST, LINCOLN HOSPITAL; ATTENDING NEUROLOGIST, NEW YORK CITY HOME; NEUROLOGIST, WORKHOUSE AND PENITENTIARY.

THE term epilepsy is a symptom; it describes the seizure, which is the leading and principal clinical manifestation of several conditions. These are the early epilepsies, the late epilepsies, the organic and the idiopathic; this is Turner's division and definition.

*Read at the spring meeting of the Nu Sigma Nu Alumni Association, Yale Club, New York, May 1, 1911.

The early epilepsies are those which occur in children and are most frequently the result of the ills of that age, as encephalitis, hemorrhage and thrombosis. The organic are those due to trauma and following focal diseases of the brain. The late epilepsies are those which appear late in life—from the third decade on. These are generally toxic in origin, resulting from alcohol and syphilis or secondary to a degenerative cardiovascular apparatus. The idiopathic epilepsies are those for which no discoverable cause can be found.

The word epilepsy is derived from the Greek. The original word in that language was "epi lambeino," meaning to fall upon. The original spelling more nearly approached the Greek word than does the present; instead of epilepsy it was epilency. Trevisa, in 1398, writing of it as was the custom in the fourteenth century, spelled it epilency. To the Ancients, epilepsy was known under many names. Each nation had a title of its own, each century added a new one. The synonyms, therefore, are very numerous. Some tribes even had more than one name. It seems to have been a disease very ancient in origin, in practice very familiar. The earliest name which has been given to epilepsy is the "disease of Hercules." By many the appellation is thought to have arisen from the severity of the disease itself. A more probable explanation is the one given by Josat, who, early in the 50's, wrote a treatise on this subject. He explained it on the theory that Hercules was himself an epileptic. This idea seems to have been shared by the writers of the day, who speak of his possessing a violent and tempestuous disposition. From Euripides and Seneca we learn that once when sacrificing to Jupiter the demi-god suddenly stopped, rolled his bloodshot eyes, frothed at the mouth, and beat the air. He then attacked and finally killed his wife and children. Next he attempted to destroy his father and would have succeeded had not Pallas intervened. After these events he fell into a profound sleep. Upon waking he professed complete ignorance of any of the events. At the sight of the carnage he was heart-broken. When one adds to this the additional facts that Hercules on another occasion had attacked his music teacher, and at twenty-three had killed some of his children the fact stares one in the face that he was more than unstable and very dangerous. The picture certainly describes the epileptic and the characteristics of the epileptic temperament.

To the Romans epilepsy was well known and called by several names. One was *morbus caducus*, from *cado*, to fall. This the laity translated as the "falling sickness"—a term which has, to a certain extent, survived even to this day. The earliest recorded instance where the term is used occurs in an old Latin publication bearing the date 1200. Gowers says that a member of the Camden Society translated the passage and that it reads: "Another property which is good for an anchoress is the 'falling sickness'—she would otherwise prove too presumptuous." The more familiar instance of the use of the term occurs in the play of Julius Cæsar. In the very first act Cassius says: "What! did Caesar swoon?" Casca replied: "He fell down in the market place and foamed at mouth and was speechless." To this Brutus added: "'Tis very like he hath the falling sickness." Among the Romans, however, the more common name was

"*morbus comitialis.*" The comitia were the large public assemblages in which the Romans chose their magistrates. Great were the formalities at such gatherings. If in one of these meetings a Roman had an epileptic attack, not only did the assembly at once adjourn, but the mere occurrence of the fit at once annulled all acts just passed and rendered void the names of any candidates already proposed.

In the time of Hippocrates the Greeks called it the "divine ill" or the "sacred disease." Cullen says that it was so called because the ignorant thought it the result of a divine punishment. Some of the old books say that the Sibyls rendered their answers in the midst of epileptiform convulsions. That the entire nation were not so densely ignorant nor so superstitious regarding its origin, however, is proven by this remark of Hippocrates: "It appears to me to be in nowise more divine or more sacred than other diseases. Men regard its nature and cause as divine from ignorance and wonder because it is not like other diseases." Celsus, in describing epilepsy, used a term which became immortal. He called it "morbus major." The French translated this into their own inimitable language and gave a name which is today the common description of the condition "*grand mal,*" because the disease was terrifying and great and grand.

The ancient Egyptians had still a different word to describe it. They, too, were ignorant and superstitious. To them the moon and the planets were wonderful and powerful bodies, the moon especially so. It exercised control over the wind and stagnant waters; it was regarded with awe and great fear. In their ignorance these barbarians ascribed many ills, especially the ills of the mind, to the evil influence of the moon. The one ill which to all nations has been clothed with the greatest awe, the greatest fear, and the greatest majesty is epilepsy. Therefore it is not strange that in Egypt it should have been known as the *morbus lunaticus et astralis;* that is, the moon and star sickness. The Greeks had the same opinion: they regarded the moon as a potent cause of ills and ascribed many of their misfortunes and attacks of sickness to its baneful influence. The Romans, in a measure closely allied to the Greeks, also shared many of these ideas and most of these superstitions.

An old appellation was Saint John's illness. Just why it was so called I have not been able to ascertain. One explanation is that Saint John, the Baptist, was a sufferer; another, that it had been observed that on the feast of St. John epileptics were most apt to be afflicted with a seizure. This could easily be explained by the fact that St. John's day was a midsummer holiday; there was not only a great access of heat, but on such an occasion the population was gathered together in crowds. Either of these would serve as exciting causes. Still another explanation is that when the head of John the Baptist was presented on a charger to Herod's daughter the features bore a strong resemblance to those of an epileptic.

The eighteenth century furnished still a newer term for epilepsy. A certain Swiss, John Joseph Gassner, who lived in the middle of this century left a short article on the "morbus daemoniacus." He was somewhat of a religious fanatic, who devised a certain set of terms or incantations to ward off the attacks. In this way he acquired great celebrity. To him at one time was actually attributed the power of curing the disease. His methods were those of the charlatan, and, like most such methods, achieved considerable success. He would visit a certain town announcing that he possessed a cure for the disease. The epileptics would swarm about him. He would then work them into a great frenzy. Innumerable seizures would result. This would be his opportunity. Forthwith standing over and surrounded by their prostrate bodies he would speak his long magical incantations. He would make these rites of considerable length so that by the time he was finished the unfortunate patients would gradually, one after another, be emerging from their fit. The populace would applaud, giving to him and his words the credit of stopping the attacks. Strange to say, the followers of such a man were numerous and numbered men of distinction. Among them was so wise and observant a man as the great physiognomist Lavater. Today Gassner would be termed a rascal and probably placed under arrest. You will, however, be more disposed to treat him with charity when I tell you that he was himself an epileptic. If you will pause a moment to consider his character you will certainly find traits much like those found in Hercules. Each was impulsive, each was irresponsible. The one was a fanatic, the other a murderer. Violence and impetuousness were familiar traits in each. These two figures of the past, the one historical, the other mythological, furnish excellent types illustrative of the epileptic temperament—a temperament which is distinctive and one not easily feigned nor exaggerated. As you analyze more carefully the character of Gassner you will recognize, as you did in the case of Hercules, the familiar signs of the epileptic.

The epileptic is a degenerate, as is shown in both the physical and mental traits. He is, as a rule, small of stature and slight of build. Somewhere about him can be found stigmata of degeneration. Fere says that of all these astigmatism is the most common and occurs in 75 per cent. of the cases. Others are the high arched palate and the asymmetrical cranium. The face itself is not characteristic. In many of these sufferers it of course shows the telltale marks of the bromide eruption and scars, which have resulted from falls. While these two signs are very suggestive they can hardly be called characteristics of the disease but rather the results. The mental condition, even more than the physical, is characteristic. Here the effects may vary from a very slight impairment to actual dementia. The most constant and the earliest manifestation is an impairment of memory. So general is this that Spratling puts the figures as high as 90 per cent. This impairment of memory affects the more recent events rather than those of earlier years. In the prolonged and advanced cases there is complete destruction of memory for both recent and remote events.

A leading characteristic of the epileptic is impulsiveness, a trait which is the frequent cause of trouble. It is this impulsiveness which so frequently leads him to violence and even to homicide. There is no disease in which the fury is so sudden and the anger so violent as in epilepsy. These attacks of rage come without warning and end in disaster. For this very reason these patients can neither be relied upon nor reasoned with. An argument with an epileptic is an impossibility: to begin one is always a mistake. Their thoughts are impetuous, their expressions explosive, their actions disastrous. Those epileptics who are neither violent nor distracted still show some signs premoni-

tory to an attack. Even the very peaceful ones at this time become irritable and emotional. A minor form of this irritability and impulsiveness is shown in their daily life. To those nearest to the epileptic he always shows an overbearing attitude and a certain degree of intolerance. Many of these patients are afflicted with periods of depression, which alternate with similar periods of exhilaration, although it is the depressed period which is the more frequent and the more lasting. Along with this unstable and ill-balanced temperament there is an element of bigotry and hypocrisy, which manifests itself in a religious emotionalism and fervour. The advanced cases, such as are seen in asylums, are especially apt to develop periods of religious frenzy. One will frequently find them reading verses in the Bible and psalm singing. Coupled with this is a latent hatred for some individual. Samt puts this phase of their character very well when he says "poor epileptics, who, with a prayer book in the pocket and the word of God on the tongue, have the most extreme wickedness in the heart."

They are egotistical and selfish. They are self-willed to a degree. It is with great difficulty that one can persuade them to adopt the right course. This is probably accentuated by the strong belief which they all have in their own ability to accomplish. As a result they are constantly getting into trouble and constantly making failures. Success to them is rarely possible. So great is this belief in their ability to accomplish that they are never willing to attribute the cause of any failure to their own weaknesses. They have a marked incapacity for any form of valuable productive occupation. It is not possible for the epileptic to carry out any consecutive or well-planned campaign. Yet at the same time there is an ability to receive a certain amount of education and of book learning. I have in mind a man who graduated first in his class at college and was full of enthusiasm and desire to succeed. In a period of ten years this man has tried fifteen or twenty different ways of getting on in life. Finally at thirty-one he admitted that his great mistake had been his failure to adopt a profession. He immediately began the study of law. He actually obtained his degree. He then entered a law office. In a few months, however, he had abandoned law and had embarked in some entirely new career. This lasted a little while, only to give way to a newer plan. At forty-five this man came to me as a patient. He had been an epileptic for twenty years. In the short time that I have taken care of him he has brought in at each visit a new scheme,—the last still being the one which is to bring great profits of success.

The mentality of the epileptic shows a gradual but steady deterioration and as the years go by he becomes more and more difficult to live with. There is no greater trial in a home circle than to have as one of the members a confirmed epileptic. The character of the life and the strictness of the régime which he has to follow serves to accentuate his faults and idiosyncrasies so that after a time he becomes unbearable. In justice to the patient home life for him ought not to be tried. The morals of the epileptic are bad. At times he is not only wayward but vicious. He is morose, sullen, and ill tempered and at no time is to be trusted. He is a member of the community who ought to be guarded against.

The medicolegal question often arises as to the degree of responsibility which ought to be attached to these people. It is a question whether the crime committed by an epileptic in an impulsive burst of rage should be excused or not. To my mind the epileptic is not responsible. He is one of the unfortunates of the earth and deserves the care and protection of his brother man. There is no disease known to mankind which is more disastrous than epilepsy. It blights the morality, dulls the mentality, and makes of the sufferer a person to be shunned.

There are two other points in this discussion of which I wish to speak: psychic epileptics and epileptic automatism.

The psychic epileptic may be one of two kinds. Either the attack may be momentary, lasting a few seconds, or the duration may be for a period covering several days. Between the two every gradation exists. In an attack of psychic epilepsy the patient as a rule performs some single act to which he is accustomed. Spratling describes a case at the Craig Colony. This man was in the habit of directing envelopes. When the attack came on he continued at his work and to all intents and purposes was doing it properly. When the attack was over, however, it was found that he had written the same address as many as six times. Another patient so soon as the fit seized him would take out his watch, look at it, make some commonplace remark, and then go on with his work. I had a patient who in these attacks always entered and walked through stores. His conduct was so normal in appearance and his external behavior so natural that no one ever suspected the existence of anything wrong.

The more prolonged attacks are those which the newspapers narrate of persons disappearing and then regaining consciousness in a distant part of the country. Some of these patients may travel for two weeks or even more, appear quite natural, excite no suspicions, and even transact some business. The condition will then suddenly clear up and the patient will find himself in a strange and distant town. The memory of the recent trip, the object of the undertaking, and the manner of starting will all be a closed chapter. He will be able to remember nothing. The time consumed in these attacks varies very greatly. Charcot has described a case of eight days in duration, but Spratling has described a case of twenty-eight days. In this time the patient traveled a great many miles and transacted a great deal of business. The attacks of psychic epilepsy are serious and dangerous. They may be heralded by a series of minor seizures, but, on the other hand, they may come unannounced as the earliest and first manifestation of the condition. During these periods assaults and crimes of all kinds may be committed. In this connection Gowers cited a famous case, that of an epileptic cabman who drove through the crowded streets of London in a complete state of unconsciousness, without accident, and without in any way remembering what he had done. I should mention here that pyromania is a favorite form for their destructiveness to follow.

The other point to which I wish to direct your attention is the epileptic automatism. This is a state in which the patient goes through a series of acts without injury to himself or others. He carries out all mannerisms and peculiarities of the normal condition. It is a noteworthy fact that he is able to transfer the acts of the normal into the abnormal, but never those of the abnormal into the normal. History tells us that many of the distinguished and

great men were epileptics, such as Caesar, Napoleon and Swedenborg. The explanation of this is probably twofold. One is that they were great not because of their epilepsy, but in spite of it; another, that they all were sufferers from epilepsia tarda, *i.e.* the late epilepsies, a condition which developed after they had achieved their great deeds.

REPORT OF A CASE OF ANAPHYLAXIS.

By WILLIAM S. THOMAS, M.D.

AND

W. K. TERRIBERRY, M.D.,

NEW YORK

W. L. W., aged 55, broker; negative family history.

Personal History.—Marked alcoholic history up to one year ago, at which time, after considerable loss of weight, patient had an attack of "blindness," which lasted some weeks, and was diagnosed by a physician as being due to diabetes. The patient recovered rapidly on a restricted diet, and since then has used no alcohol. He has apparently been perfectly well during the past six months on ordinary diet.

Present Condition.—On April 20, 1911, at 6:30 P. M., the patient received 8 c.c. (3,000 units) diphtheria antitoxin subcutaneously in the abdominal wall. There was no bleeding through the needle. Antitoxin was administered with the patient in a recumbent posture. At the end of five minutes he felt well and arose, but began to sneeze continuously and his nostrils became obstructed. He soon grew dizzy and complained that everything was growing dark. About fifteen minutes after receiving the injection the patient was cyanotic and his inspiration was noisy and difficult. Preparations were made for intubation of the larynx, if the necessity should arise. He raised himself on one elbow in the bed, laboring for breath, with frequent cough and expectoration of pinkish serum. His face, especially about the eyes, was swollen. The conjunctivæ were injected; the skin was cold and covered with perspiration, and the pulse was absent in both radial and brachial arteries—even the apex beat not being palpable.

A hypodermic injection of atropine sulphate, gr. 1/100, and strychnine sulphate, gr. 1/30, was administered. In a few moments the respiration became more quiet and at the end of fifteen minutes the patient sank back to the recumbent posture and the serous expectoration ceased. At this time the patient had an urgent desire to defecate and passed a large, brown, semiformed stool. Twenty-five minutes after the injection of antitoxin the radial pulse became barely palpable. The blood-pressure, however, was too low to be recorded with the sphygmomanometer. The skin all over was brightly flushed. The tongue was swollen, its edges showing the impressions of the teeth; the soft palate and uvula were edematous and their vessels were injected. Twenty minims of a 1/1000 solution of adrenalin chloride with chlorotone were now given hypodermically. At the end of one hour the blood-pressure was still too low to record, but the apex beat had attained fair force and was regular, though rapid.

Two hours after the serum injection the patient drank a pint of water which he promptly vomited. The regurgitated liquid was pink and frothy. During the efforts at vomiting the pulse rate sped up to 150 but afterward dropped to 96.

At two hours and a half the blood-pressure had risen to 115 mm. mercury. The edema was diminishing and the erythema had about disappeared. Temperature 98.4°, pulse 96, respiration 18.

At three hours the conjunctivæ had become clear and the edema was now only slight, but the nares were still obstructed. The pulse became accelerated on slight exertion.

At three and one-half hours the arterial pressure was about 105 mm. The patient went quietly to sleep about four hours after the antitoxin injection, his symptoms having now disappeared.

Examination of the first urine voided after the antitoxin injection showed a specific gravity of 1032, neutral reaction, no albumin, a trace of glucose.

At midnight the temperature had risen to 101.8° F., but reached normal the following morning and remained so. There was considerable thirst during the night and the patient drank a good deal of water. No further symptoms developed until nine days later, when a general urticaria appeared with much edema of the eyelids. This continued three days and then disappeared.

Comment.—This patient had never been subject to asthma or hay fever, but for many years had had a tendency to sneeze a great deal at all times of the year, a characteristic which the patient shared with his mother. He had never noticed any symptoms or discomfort from the close proximity of horses, nor had he ever had an injection of antitoxin before.

It may be proper to call attention to the possibility that the erythema and thirst may have been due to the hypodermic injection of atropine. If so, his sensitiveness to a moderate dose of this drug would be of interest in connection with the patient's oversusceptibility to horse serum.

The site of injection at no time showed any signs of infection or reaction.

THE LIMELIGHT ON PNEUMONIA.

By JAMES R. MITCHELL, A.B., M.D.,

FORT WORTH, TEXAS.

LECTURER IN CHEMISTRY, FORT WORTH MEDICAL COLLEGE.

This conception seeks to explain the success obtained by good men and true. Sir Lauder Brunton considers calcium chloride the ideal heart tonic in pneumonia. Sir James Barr gave calcium chloride because it thickened the sputum, for as old as pneumonia is the law: The thicker the sputum, the more favorable the prognosis. Calcium chloride was prescribed by A. Crombie, because it shortened the course; by D. M. Moir, because it relieved suffering and distress; by James Couldrey, because it stopped headache and slowed the pulse. Selkirk recommended lime in pneumonia because he invariably found cement laborers and workers in lime kilns to be immune to lung infection. These men used calcium symptomatically and got results. Let us see if their symptomatic treatment had a justifiable pathological basis.

We will start our investigation in the bacteriological laboratory. Here we find the pneumococcus notorious for resisting growth in ordinary bouillon culture. For a time it grows fairly well, but soon snuffs out. Add calcium carbonate to the broth culture, however, and the reluctant growth assumes a splendid vigor. The natural deduction follows that the pneumococcus extracts calcium from the medium in which it grows. When all the calcium is exhausted the culture dies. The thought next

comes: If calcium is necessary to grow the pneumococcus in the test tube, must calcium not necessarily be present to grow the pneumococcus in living animal tissues?

We proceed to the physiological laboratory and renew our acquaintance with the experiment of the beating excised heart. A quarter of a century ago Sir Sidney Ringer discovered that while hydrant water and salt sustained perfect pulsations in the frog's excised heart, yet distilled water and salt allowed the heart quickly to lose contractile power. Investigation shows that calcium was the stepping-stone from the few contractions of distilled water to the many contractions of tap water. Ringer correctly attributed the continuance of the normal heart beat to the presence of calcium salts in the living blood. In other words, when calcium is deficient in the circulating blood the heart will refuse to beat.

We visit the clinical laboratory for our third test. We boil and filter the urine of a pneumonia patient and add a few drops of nitric acid. To this mixture we add an equal quantity of 3 per cent. silver nitrate. No curdy precipitate appears. This means that in pneumonia the chlorides are absent or markedly diminished.

In vain have I searched my text books for an explanation of what happens to these kidnapped chlorides. No writer cared to hazard a theory. A case in the children's ward gave me the clue. A child with pneumonia vomited persistently. Usually the vomiting of children, so common in pneumonia, has been ascribed to the mucus which is swallowed by children, and not expectorated, as by adults. With this child the vomitus contained no mucus. It did, however, smell acid, and a test showed it highly acid with hydrochloric acid. Since then I have examined stomachs of many patients with pneumonia and have found all to be hyperacid with hydrochloric acid. The chlorides, then, are withheld from the urine and retained in the body for the formation of an excessive amount of hydrochloric acid in the stomach. Berend comes near the mark when he asserts that pneumonia of children is constantly associated with digestive disturbances.

We know that chlorine is combined in the blood and tissues with sodium, potassium, and calcium. We know that calcium is most essential for the growth of the pneumococcus. I contend that the chlorides are retained from the urine and dispatched to the stomach as hydrochloric acid, in order that this hydrochloric acid may unite with the minerals of the food, especially with the mineral calcium, and so restore the mineral balance which is being destroyed by the ravages of the pneumococcus. I contend, further, that many symptoms of pneumonia are direct symptoms of calcium poverty, the calcium being abstracted for the growth of the pneumococcus and for the defensive agents which fight the pneumococcus.

Pneumonia is not merely "an inflammation of the lungs." It is a systemic disease. Its organism multiplies in the circulating blood. The lung lesions are a defense. All symptoms of pneumonia, even dyspnea, may be present without any lesion of the lungs. Mice, suffering from pneumonia are dyspneic, although pulmonary consolidation is never present. The human lung is solid when the crisis has passed, but the pneumococci disappear from the circulation as soon as the crisis starts. In syphilis or in typhoid the lymph glands fight the disease. In pneumonia there is no glandular involvement. The lungs take the place of lymph glands and constitute the organs of defense. The organs of respiration in health play the accessory role of lymph glands in disease. In the desperate battle with the pneumococci nature favors the host by choosing the lungs as the arena. The pneumococci hurl their challenge. The host exercises his prerogative of weapons and location—the white blood cells the weapons, the lungs the arena. Instead of a battle cry, "To arms," the cry of the white blood cells is "To the lungs." Consider how wise is nature's choice. The swift-moving blood current is too unstable an arena, but every drop of blood passes through the lungs again and again. The lungs are the nets to ensnare the circulating germs. In the presence of the air in the lungs the blood coagulates and precipitates fibrin. The fibrin entangles the pneumococci much as the cat retains a mischievous mouse in her claws. Then the ever-vigilant leucocytes crowd into the meshwork and devour the ensnared germs at leisure.

The most frequent first symptom of pneumonia is a rigor. Repeated *x*-ray pictures have shown that this rigor occurs long before any consolidation of the lungs. What is its significance? Physiology tells us that a chill is a whip to accelerate the venous current. The rigor, then, means that the venous blood is being accelerated. The venous blood is heading directly to the lungs, nature's chosen arena.

After the rigor the temperature ascends. Metabolism is active. The fever is an agent of defense to hinder the propagation of the pneumococci. Pasteur proved the protective power of heightened temperature in birds. The hen has a normal temperature of 104°, and is normally immune to anthrax, which will not thrive at 104°. Pasteur lowered the temperature of hens by wetting them or standing them in cold water. Hens so treated were susceptible to the anthrax to which their normal temperature gave them immunity.

I have already laid stress upon the decrease of the chlorides in the urine, the chlorine being transported to the stomach as a hyperchlorhydria. The hyperchlorhydria is neutralized by the mineral alkalis of food to increase the alkalinization of the blood. Water is rich in minerals; fortunately, nature gives the patient great thirst. Likewise, the patient has little desire for food. Milk alone satisfies. There is no blood to spare for the complexities of digestion. The blood is most needed for the lungs.

Active metabolism encourages an angry, bounding pulse. This keeps the machinery of defense in action—the more blood to the lungs, the more germs entrapped and destroyed. In moribund cases the blood coagulates slowly. It has lost its calcium to nourish millions of pneumococci and to manufacture the fibrin which ensnares these pneumococci. Usually the blood is rich in leucocytes; and well, too, for the prognosis varies directly according to the number of white blood cells. Thirty thousand strong, they are swiftly transported to the arena. Each leucocyte bears its hoard of calcium to activate the opsonins of phagocytosis, for no enzyme will act without the presence of calcium. The leucocytes exude from the pulmonary vessels into the arena and devour the opposing pneumococci.

Consider the drain upon the calcium of the blood; its use for food by the pneumococci; its loss in the extensive formation of fibrin; its necessity for stimulating six times the normal number of leucocytes; its requirement for activating opsonins and bacteriolysins. Remember that this loss of calcium

is proven by the delayed coagulation time of the blood and quantitative tests of the urine. Reflect that Ringer's experiment upon the beating excised frog's heart proves the necessity of calcium to the proportion of 1:10,000 in the blood for the maintenance of the heart beat. Then know that heart failure—that bugbear in the treatment of pneumonia—is due to the poverty of calcium in the circulating blood.

Pain in the chest originates from a fibrinous pleurisy overlying the consolidated lung. This pleurisy fixes the lung, making a solid fighting ground for the contest. "A circulating leucocyte gathers no pneumococci." In the solid lung phagocytosis is easy. For the time being the respiratory function of the consolidated lung is entirely lost. The function of defense reigns supreme.

If the secretion is scanty there is little cough. Any secretion in the bronchus is a foreign body, and with children nature provokes drastic vomiting to expel this foreign body. Clinicians affirm that the thicker the sputum the more favorable the prognosis. The thought next comes, "Why give expectorants, all of which decrease the coagulation time of the blood, thin out the expectoration and irritate the stomach?" The frequent occurrence of convulsions confirms the necessity of calcium in pneumonia. In a previous paper,* I showed that the convulsions of eclampsia are due to a calcium poverty of the nerves. I hold that the convulsions of pneumonia are due to the same cause. The poverty-stricken blood extracts calcium from the nerves, and the nerves writhe in protest.

We hear much concerning the toxins of pneumonia, yet nothing remotely resembling a toxin has been isolated from the cultures of the pneumococcus. The toxemia of pneumonia, like the toxemia of eclampsia, is simply an expression of calcium poverty. Death from toxemia is death from calcium poverty. Death from toxic heart failure is death from lack of calcium in the circulating blood.

Drennan has laid emphasis upon the fact that before an organ can undergo fatty degeneration calcium must be present to form soluble lipoids out of the fat. Gray hepatization is a fatty degeneration of the fibrin and leucocytes after they have fulfilled their mission, and the calcium of the blood unites with the fatty particles to form soluble lipoids. Gray hepatization, or fatty degeneration of lung débris, occurs coincident with the crisis. The added drain upon the already depleted calcium supply is enormous. No wonder heart failure is so frequent —especially at the crisis of pneumonia.

Edema of the lungs is the complication of impending death. MacCallum has shown that the *Eucharis multiformis* is very active in artificial sea water, which is calcium-free. When calcium is added to the sea water the contractions of the Eucharis immediately cease. MacCallum says that calcium appears to alter the permeability of contractile tissue to ions, inhibiting contractions by decreasing permeability of fibrils. So with edema of the lungs —when calcium is deficient in the tissue fluids the tissue is readily permeated by such fluids. Nothing reduces a cutaneous edema so quickly as a salt-free diet combined with large doses of calcium lactate. Edema of the lungs in pneumonia compares in origin with the edematous joint of the hemophiliac—an effusion always associated with calcium poverty.

*"A New Theory of Eclampsia," Medical Record, November 19, 1910.

Pneumonia is a nine-day obstacle race between the pneumococci and the leucocytes. Don't stimulate. The body can ill afford spurts. Support the body. At best it is an unequal fight for the pneumococci on hostile soil. Waylaid in the dark recesses of the lungs, what chance have they in a resistant body? The whole pathology of pneumonia is a sign language against the use of local treatment. Expectorants, inhalations, pulmonary antiseptics are meddlesome and worse than useless—meddlesome because they paralyze the leucocytes as well as retarding germ growth; useless because healthy leucocytes are abundantly able to cope with any pulmonic infection. Pulmonary antisepsis ranks with the use of intestinal antisepsis in typhoid—both provoked by a hastily assimilated knowledge of pathology. Did you ever stop to think how fortunate that typhoid ulcers are in the inaccessible small intestine instead of in the rectum? Typhoid would then have become a surgical disease. How the meddling surgeons would have irrigated, curetted, and daily dressed those ulcers! Until they learned better! It is painful to contemplate. Yet local treatment of the pneumonic lungs is as illogical as the local treatment of the typhoid ulcers. There is no laboratory antiseptic to compare with normal blood.

The logical treatment of pneumonia is rest, support, and calcium. Don't sit your patient up to examine him. Don't curse him with the company of his friends. Don't torment him with poultices and ice-bags. Cold sponge-baths and cold-air treatment are harmful and brutal. Nature provides the turbinates to warm, inspired air. Cold air treatment antagonizes nature. Warm air is just as fresh as cold air. Children instinctively shrink from a cold bath. In fact, you cannot give them a cold pack unless they are in stupor or delirium. When an adult is near the borderline of death he is as delicate as a child. His fever needs no special attention —no cold pack, no antipyretics. When you apply cold packs you repeat Pasteur's experiment to the detriment of your patient. Cold packs! So quickly does the doctor forget how a similar exposure to cold and dampness preceded the disease and chilled the patient's vitality so that he became an easy victim for the treacherous pneumococci. Statistics show that cases in which the fever has ascended to 105° suffer no higher mortality than those in which it has never risen above 103°. Fever does not constitute the danger. Fever merely announces the danger. You would not gag the dog that barks a warning against a thief. Why freeze the fever—your diagnostic friend? Is it logical to run the fever down one degree and then try to delude yourself into the belief that your patient must be better? Because you gag your dog must your house needs be safe from intruders?

Pneumonia in alcoholics is an ugly disease. Yet doctors there are who make a routine of alcohol in pneumonia—a drug that delays coagulation, relaxes the vasomotor system, wears out the heart. The beating excised heart soon stops when perfused with alcohol. If pneumonia often winds up an alcoholic debauch then alcohol often winds up a pneumonic debauch.

Guaiacol increases lung secretion, which is another way of saying that it predisposes to edema of the lungs. Lung antisepsis is meddlesome and is a poor substitute for the phagocytosis with which it interferes.

Quinine is undeniably harmful in pneumonia.

To quinine is correctly laid the responsibility for case after case of delayed crisis. Quinine retards the growth of the pneumococci, 'tis true, but quinine also paralyzes the 30,000 leucocytes per cubic millimeter which nature has prepared for your patient's defense. Would you beat a dog to drive off his fleas? It would be more illogical than to paralyze your patient with quinine when he needs only intelligently directed support.

Calcium is the rock on which our treatment is built. Ferments and enzymes can be activated only in the presence of calcium. Calcium is needed for activating the enzymes of phagocytosis. Tuberculosis and pneumonia are almost unknown among men who work in lime kilns. Many observers corroborate this fact. All my cases treated with calcium ended by crisis—a crisis unattended by collapse, for the heart was strong; a crisis which, transferred to the temperature chart showed a line straight as the crow flies.

The curative treatment is a diet solely of equal parts of milk and lime water, supplemented by ten grains of calcium chloride every three hours. No other treatment has ever been needed. In all diseases where pneumonia is a threatening complication—in measles, fractured neck of the femur, eclampsia—the administration of calcium in diet and medicine will abort lung complication. The proof of my theory is in the clinic. My experimental series of cases numbered thirty-three. No patient received other treatment than calcium, as milk and lime water diet, and medicinally as calcium chloride. Of the thirty-three, but two patients died, both within twelve hours after admission to the hospital, which means before the treatment was fairly instituted.

McKechnie has well said: "In a violent and dangerous disease like pneumonia, often threatening a valuable life in its prime, there is a great temptation put upon the medical man in charge of the case to 'do something.' The blood is swarming with pneumococci, and somewhere, somehow, the body is manufacturing those subtle substances—antitoxins, lysins, complement, and what not—which, given the time, will destroy the parasites and their poisons in about a week. This is the cure. Nature effects it; never the medical man."

Every aspect of pneumonia bears testimony to the value of calcium. We know that the pneumococcus extracts calcium from the medium in which it grows. We know that it extracts calcium from the human culture medium, for calcium products are increased in the urine and feces during pneumonia. We know that convulsions are caused by calcium poverty, and we have no reason to deny that this calcium poverty is the cause of the convulsions in pneumonia. We know that a hyperacidity is a chemical invitation for alkalis, and we suspect that calcium is the bidden guest in pneumonia. We know that calcium is absolutely required for the activation of lysins and opsonians, and all the phenomena of leucocytosis. We know that gray hepatization is impossible without the presence of calcium. We know that edema of the lungs and collapse of the heart occur only when the coagulation time of the blood is delayed. Gentlemen, is there any doubt in your minds concerning the importance of calcium in pneumonia?

If I had the teaching of physiology I would again and again perform Ringer's experiment upon the beating excised heart until its pulsations would sweep aside all temptation for my students ever to substitute alcohol for calcium in pneumonia. If I had the teaching of pathology I would show under the microscope how the leucocyte in a calcium solution is spoiling for a fight with the germs that surround him; how in a quinine solution the leucocyte floats listlessly about, all indifferent to the appetizing germs it was born to devour. The vision of this paralyzed leucocyte would haunt my students whenever they were tempted to substitute quinine for calcium in pneumonia.

THREE CASES OF NON-PARASITIC CYST OF THE SPLEEN.

By H. A. ROYSTER, M.D.,

RALEIGH, N. C.

I HAVE had occasion to remove the spleen but three times and each time for cystic enlargement of the organ. The first was a simple cyst of medium size, the second a large blood cyst, and the third, largest of all, a suppurative cyst (abscess). There was no special trouble in the operations, except the last one, in which unusually dense and widespread intestinal adhesions were encountered. An uncomplicated splenectomy is certainly not a difficult procedure, least of all from fear of hemorrhage, as the pedicle is in most cases easily secured. Removal of the whole organ is the only satisfactory mode of treatment for a splenic cyst. Partial excision, puncture, or open drainage are often more serious than splenectomy and are not to be thought of unless it seems impossible or dangerous to do a total extirpation.

Though conversant with the matter in a general way, I have never looked up the literature of this subject. In a recent paper describing one case C. G. Darling* states that "non-parasitic cysts of the spleen seem to have been rare in this country, at least only a small number have been reported," and that Powers' case in 1906 was the first one recorded in the United States, while Johnston (1908) had found only nineteen in which splenectomy had been performed. I therefore present the following cases merely for the purpose of adding them to the published list.

The first one was set forth in the Transactions of the Medical Society of the State of North Carolina for 1901 (pp. 138-140), but did not appear in the periodic literature. This antedated Powers' paper by five years. The other cases are of more recent occurrence and are here recited for the first time. A singular fact concerning these cases is that all three of the patients had had chills and that in none of them was the plasmodium demonstrated. Two of the patients were from so-called malarial regions, but it seems unlikely that malaria had anything to do with the splenic enlargement.

CASE I.—A colored school girl, twenty-four years old, has been healthy with the exception of chills, which she thinks were probably due to malaria. Menses began at the age of thirteen, always regular, but very free; she has indigestion occasionally, but complains of no special pain. In November, 1900, she felt an enlargement in her abdomen about the size of a hen's egg; it gradually increased in size until the present time (May 16, 1901) when it seems to her as large as the fist. Examination: Patient well nourished. There is in the abdomen just above the symphysis a central globular enlargement, smooth, of the size of a large orange, with a linear mass extending upward to the left; on bimanual examina-

*MEDICAL RECORD, January 21, 1911.

tion the growth appeared to move with the uterus; the cervix was rather soft. The diagnosis was considered obscure, opinion inclining to fibroma of the uterus, with the possibility of its being an ovarian cyst. No plasmodia were found in the blood. Operation: May 18, 1901, at St. Agnes Hospital. A three-inch abdominal incision was first made over the most prominent part of the tumor. When it was exposed and seen to be cystic, the fingers were swept around the broad ligaments, but no pedicle was found in that region. The mass was pushed upward and disappeared entirely from view, but was felt through the abdominal wall in the left hypochondrium. The incision was prolonged until it reached above the umbilicus, when it was discovered that the growth was a cyst of the spleen. After separating the adherent omentum, in which were found two smaller cysts, the vessels were tied with a doubled silk ligature and the whole spleen removed. Not a drop of blood was lost in this maneuver. The right ovary, which contained two or three cysts, was also removed. The abdomen was closed without irrigation or drainage. The patient had a perfectly normal convalescence and made a nice recovery. She continued to have chills for several months. She is now married, lives in another State and has recently written to say that she is in good health. The specimen after removal was seen to consist of a spleen nearly normal in size and shape, with a thin-walled cyst growing from its lower portion, containing about a pint of clear, watery fluid. Dr. R. H. Whitehead, who examined the specimen, reported that it was a serous cyst of the non-parasitic type.

Case II.—Young white man, age twenty-two, cotton-mill operative, first seen March 5, 1910. He complained of pain in the upper abdomen, chiefly on the left; also of "soreness under the breast bone." From September 1 to December 21, 1909, he had chills at irregular intervals; he never had any before that period and has had none since. About the time the chills began he noticed a swelling of his abdomen, which has remained and grown gradually larger. Examination shows the abdomen distended in its upper region by a huge cystic mass, fifteen inches in its longest diameter. It was easily traced to the left and a diagnosis of cyst of the spleen was made. The urine was normal: the blood analysis gave 5,000,000 erythrocytes, 14,000 leucocytes, and 70 per cent. hemoglobin; hook-worm examination was negative. Operation: March 7, 1910, at Rex Hospital. A high left-rectus incision exposed the tumor, which showed dark liquid contents through its thin wall. A trocar was inserted but the sac was very friable and the whole cyst suddenly collapsed, discharging four quarts of bloody fluid. The sac was then carefully peeled off from the abdominal walls, liver, diaphragm, stomach, and intestines; the spleen was turned outward, the pedicle ligated with linen and whipped over with catgut. The wound was closed in layers without a drain. The patient ran a pleasant postoperative course and was in the hospital only seventeen days. He is now restored to health, having made a considerable gain in weight. This large blood cyst sprang from the inner surface of the spleen and the organ itself was enlarged, weighing nine ounces. As traumatism may play some part in such a case, it will be well to state that after the operation this patient remembered that during his work he often had occasion to press his sternum and the lower part of his chest against a frame run by machinery. Dr. C. A. Shore, Director of the North Carolina State Laboratory of Hygiene, examined the specimen and made this report: "Wall of cyst consists of splenic tissue; not hydatidiform. Spleen hyperplastic."

Case 3.—Colored woman, twenty-three years of age, sent to my clinic January 20, 1911. One child, five years ago. Has no symptoms referable to her pelvic organs. Has had chills and fever every summer for several years except last summer (1910). Swelling of her abdomen has been noticed for two years or more, and she suffers increasing pain from pressure of the mass which has

Case III. Large tuberculous cyst (abscess) of the spleen.

grown rapidly in the past few weeks. Examination: A rather stout healthy-looking woman. Temperature normal. Chest and pelvis negative. There is an enormous distension of the abdomen, particularly in the left upper quadrant, where the lower ribs are everted (see Fig. 1). Fluctuation is easily elicited. Some respiratory embarrassment is evident. All signs seem to warrant the diagnosis of cyst of the spleen. Operation: January 21, 1911, at St. Agnes Hospital. Through a ten-inch incision in the left rectus, beginning at the lower border of the ribs, an attempt was made to deliver the cyst entire, but it ruptured on handling and the contents poured into the cavity. There escaped at least six quarts of a yellow, purulent fluid, of thin consistency, with cheesy flakes, and a faintly disagreeable odor. Troublesome adhesions to diaphragm, left abdominal wall, kidney, stomach and transverse colon required time and care in their separation; a part of the sac had to be left at the lower portion where it was immovably attached to the small intestine. The splenic pedicle was ligated with linen and the organ removed along with the cyst walls. There was no unusual bleeding. The abdomen was wiped out as quickly and as thoroughly as possible and three drainage tubes were introduced; one straight through the upper part of the incision down into the very deep cavity which the cyst occupied; one through a stab wound just above the pubes; and one posteriorly between the two lower ribs on the left side, going directly into the dependent space in which oozing might occur. The patient showed a marked degree of shock, but she soon reacted. Her respiration was chiefly affected. The head of her bed was elevated and she was propped on pillows from the first. Normal salt solution was administered continually by rectum for two days. Pain in the left chest, rapid breathing, and a moderate elevation of temperature were present for nearly a week after operation, but they subsided without serious import: no sign of

pleurisy was discovered. Slowly but surely the chest wall resumed its natural outline. The wound healed properly and the patient was discharged February 8, 1911. An examination of the specimen by Dr. Henry G. Turner revealed a spleen nearly normal in size, but honeycombed with multiple areas containing the same material as that evacuated from the cyst. Cheesy masses were deposited in and around these small cavities. The microscope confirmed the clinical opinion of tuberculosis. On the basis of a strict classification this case might not be included under the title of this paper, since it proved to be a turberculous abscess. But the physical signs were those of a cyst and the character of its contents were not such as to modify the diagnosis or the treatment.

CHRONIC BLOOD INFECTION SUCCESSFULLY TREATED WITH STAPHYLOCOCCUS AUREUS VACCINE.

By T. W. BEEMAN, M.D.,

PERTH, ONTARIO.

John M., aged 46, a Canadian employed in a grain elevator and a resident of Manitoba, consulted me in December, 1910, giving the following history: In July, 1909, he noticed a few pustules on one ala of the nose. He had been engaged temporarily in removing fresh earth from a cellar, but it is impossible to say whether this had any connection with the pustules on the nose. These soon disappeared, but shortly afterwards he had an attack of what was thought to be typhoid fever; he was for 35 days in a hospital, where it was soon noticed that the temperature curve was not of a typhoid character. Shortly after leaving the hospital a swelling appeared on the back of his neck that was very slow in developing. It was not attended with much pain at first, but, later on, interfered considerably with the act of swallowing. Several efforts were made to locate pus in this swelling before its presence was established, and several weeks after the first symptoms of the adenitis appeared a large abscess was opened in the median line over the second cervical vertebra. This continued to discharge for several months. From that time, October, 1909, until December, 1910, he was never without an abscess either forming or discharging. All of these abscesses were in muscular tissue and very deep seated. His condition at that time was far from promising. He was greatly emaciated, had no appetite nor energy, and dreaded going out of doors in the cold. He slept badly but had no night sweats. His temperature would run up to 100° or 101° for a few days before an abscess was opened. His complexion was sallow and his general appearance was very characteristic of a septic condition. The bowels were obstinately constipated and there were no albumin, tube casts, or sugar in the urine. A blood count showed 2,600,000 red blood cells. A very large abscess was forming on the anterior surface of the right thigh when he consulted me. Taking proper precaution I ran an exploring needle into the abscess and withdrew some pus. In this I found staphylococci in considerable numbers. Not having the facilities for making a culture from the pus, I sent small quantities to pathologists in both Kingston and Toronto, connected with the Provincial Board of Health of Ontario. Both pathologists very kindly reported to me within 48 hours that the cultures showed the presence of *Staphylococcus pyogenes aureus*. I began giving him injections of a stock vaccine of this microorganism, the first injection being 200,000,000 of the killed germs and increasing the dose until the sixth and last, giving the full amount, 400,000,000. After each injection he exhibited the characteristic symptoms of buoyancy, depression, and lastly a period of decided improvement. Injections were given about 8 to 10 days apart. All injections were given as near as possible to the site of an abscess. In every case the abscesses began discharging freely for a day or so after an injection. No rash nor, in fact, any disagreeable symptoms followed the administration of the vaccine. Each injection was given under the most scrupulous precautions, as also all abscesses were carefully opened. I might also add that some of the abscesses were so deep that drainage tubes had to be introduced. The pus from the newly opened abscess was free from odor, thick, and uniform in color, in fact, was exactly what we used to know as "laudable pus." Improvement was most marked in every way as soon as he began receiving the vaccine and he is to-day in his normal state of health. He gained 25 pounds in weight during the last two weeks of treatment and has now a good appetite and digestion and lots of energy.

Two things strike me most forcibly as the result of my study of this case. One positive and one a question. First, it would seem as though the clinical symptoms were a sufficient guide to treatment without the difficulty of obtaining the opsonic index of the patient; and, secondly, the question naturally occurs: what other treatment would have offered any prospect of a cure?

"HEAT WAVES" AND "HEAT STROKES": CLIMATIC CURRENTS, ATMOSPHERIC AND OCEANIC.

By JOHN KNOTT, A.M., M.D., Ch.,B. & D.P.H. (Univ. Dub.); M.R.C.P.I.; M.R.I.A., etc.

DUBLIN, IRELAND.

The significance of *animal heat,* in association with animal life in its higher types and aspects, is thoroughly familiar to all intelligent members of humanity; although the more critically discursive, or dialectic, may still be found to defend the thesis that it is not yet completely understood by any. As a mere matter of fact, the production and regulation of calorific supply, and the thermometric standard of the same, continue to remain—what they have been evermore—a mystery, or a *miracle* (the name does not matter), which few ever think of as such, from the fact that it has always been before them, as well as in and around their own persons. The problems of heat and climatic temperature have, however, pressed themselves this year into a prominence so exceptional that its practical interest has been regarded by a large proportion of the members of the Anglo-American communities on both sides of the Atlantic as hardly second to those of the recent historic prize-fight. The contemplative philosopher may easily find in his observations of the cyclic periods of existence arguments—and not a few—in support of the antique view that man can at best regard himself as but a nexile on the surface of this planet; and a heavily handicapped, and frequently persecuted, one at that. For meteorological conditions will from time to time arise which tend to persuade him that his external prosperity and comfort, and internal sensations and

conditions of well-being, are a good deal at their mercy—even when housed in conformity with the most righteous precepts of modern luxury and sanitation and decorative esthetics. In presence of the most effective provisions for material comfort that can be supplied by the combined counsel and effort of the geologist and meteorologist, the architect and the upholsterer, the decorative artist and the sanitary engineer, the attitude of the meniscus which forms the floor of the Toricellian vacuum, and the direction of the point of the horizon from which "proceeds" the original "breath of life," will be found to influence the equanimity, and tincture the phantasmic presentations of external and internal rectitude of even the tenant of the modern palace; whether a high bred scion of a long line of royal ancestors, or the vulgar compound of Eastern thug and Western attorney who boasts of the fact that he is not merely a "self-made" man but an autocratic millionaire. The passing change of the atmospheric medium in which we live, and move, and have our being, does not fail to influence by its variations the physical and mental sense and appreciation of well-being of every dweller at the bottom of the "spiritual" ocean which surrounds and supports us all. Such considerations, and the feelings which have given rise to the same, are from time to time reinforced by the irregularly periodic reminders which arrive from the various points of the compass: of the emphatic displays of meteorological phenomena (seasonal, thermal, pluvial, nebular and electric) which startle the subjacent denizens of the terraqueous surface of this restless and unrestful globe. What is the primordial source of the disagreeable influence of the easterly breeze on the temperamental equilibrium of the palefaced descendant of the original exiles of the Garden of Eden?—is a question which is being asked, pretty continuously, audibly or inaudibly, consciously or subconsciously, by one, more, or many of the more thinskinned inhabitants of western Europe. And there are some who cannot be brought to accept the diminished proportion of aqueous vapor as a satisfying explanation. The vagaries of the climate of the British Isles are, of course, not merely celebrated—or notorious, to use the (more appropriately) cacophonous term; they have secured for themselves the worthy heritage of a series of proverbs. A prominent public speaker and art critic announced to a large audience on one of the early days of July, and in one of the leading British seaports, that "our climate makes our national art a dull affair"; and the enunciation of that statement inspired a well known poet of the same nationality to ask, in the columns of a London daily paper:

> What is the origin and cause
> Of all the breaches of the laws
> Put down to human nature's flaws?
> Our climate.

So that a new importance has been given to the statistical fact that the brightest and sunniest part of the year reaps the largest crop of suicides, while the gloomiest and apparently surliest season yields by far the most meager return. The Parnassian commentator followed the above query by another, which will probably appeal to most readers—in the illumination of recent experience:

> What turns our best-laid schemes awry,
> Makes profits low, expenses high,
> And even humour hard and dry?
> Our climate.

Thus is man morally, as well as physically, enslaved by the influences of the gaseous ocean at the bottom of which he has crawled—with occasional attempts at climbing—for so many generations; and in which he has at last commenced to swim, with highly artificial fins and with a fairly encouraging modicum of success!

The sources of animal heat, and the physical—and *"vital"*—mechanisms which preside over and duly regulate the production and distribution of the same are far too complex (and too remotely located in one of the darkest areas of the Cimmerian Continent of Science) to be fully discussed in a communication of even a good deal above the average longitude. But some of the leading features may be touched—and, if luminously, the interest of reading cannot fail to be very markedly emphasized by the experiences of the current year. For it was not merely the British artist whose functions were impaired during and by the passage of the record marking electric and calorific waves of the present summer; these are known to have modified the professional efficiency of even the crossing sweeper at his familiar metropolitan corner of industrial refuge, and of the subterranean coal miner even in the best propped—as well as dust-free, whitewashed, and electrically lighted—gallery of the carbon lode which he had brought himself to regard as his workshop, if not his home. Thus the question of the mystery of "caloric" has been brought nearer to the hearths and homes of "intelligent and educated" citizens, on both sides of the Atlantic, by the anticyclonic phenomena of the present summer. The arrows of the far-darting Apollo have been shot over larger areas than usual; also more forcibly; and, accordingly, did not fail to penetrate more deeply. And the incongruous and inexplicable mixture of moods displayed by the aerial Juno have also proved to be correspondingly conspicuous—even when least esthetic or hygienic. So that most inquisitive readers have been led of recent weeks to ponder on the interaction of life and heat, of mind and atmosphere, of the internal *spirit* and the external πνευμα. Why do a few degrees of elevation of the thermometric index in the external gaseous medium afford reliable testimony to the lowering of the output of physical energy by the animal frame, and even to a dulling of the intellectual luminosity that enlightens the governing and distinctive faculty which characterizes the self-styled "lord of creation" himself? The facts have always been so familiar as to have evaded inquisitorial research; nevertheless the mystery of each is permanently present and profound—even to a depth beyond the reaches of our sounding lines—in the respective media. The mental apathy which excess of heat tends to produce—more especially in a moist atmosphere—can hardly have failed to suggest to some observant readers a physical comparison of the struggle against *insolation* which attracted the poetic attention of William Shakespeare and the amateurish philosophy of the contemporary (if not exactly identical) Francis Bacon. I refer to the struggle of a newly lighted fire against the brilliant beams of a torrid sun, and the lively sense of relief which it actually seems to express—and with which it unquestionably progresses—when the latter have been effectively screened off. The great furnace for the production of *animal heat* is the *muscular* system, and some amateur advocates of the philanthropic foresight of Nature—and her faithful conservation of all the powers with which

she has been entrusted—would be pretty surely found to suggest that the effect of heat on the neuromuscular system has at least one salving result: in tending to lower the evolution of muscular caloric, by restraining the expenditure of muscular energy.

Then the modification of the functional activity of the faculties of the human organism—both mental and physical—which results from exposure to unusually high temperature is, of course, very largely due to the alteration of the standard of necessary output of waste material by way of cutaneous transpiration. The average denizen of our busy and broiling thoroughfares during the working hours of our trying canicular days rarely realizes the vast importance to the well-being of his system which is represented by the *continuous* activity of the cutaneous glands—even when the quantity of fluid which these eliminate from the systemic circulation never attains the cumulative—visible and slightly odorous—formal standard which is usually connoted by the Anglo-Saxon substantive term *sweat*. The relationship of the physiological activity of the human integument to the coexisting conditions of atmospheric heat and moisture are very peculiarly complicated and are so peculiarly influential as to furnish ample food for research and reflection to the philosophical physiognomist and to the philanthropic politician. For as the healthy condition—and available function—of every organ and tissue of the animal mechanism depends (for the moment), in the last resort, on a due supply of healthy blood; and as the healthy human body always presents the well known standard of temperature (of which the continuous regulation is one of the most marvelous of the innumerable miracles which are never recognized as such because they are being continuously performed directly before our eyes); while the maintenance of the same means the exercise of a perpetually mobile adaptation of the internal conditions of the living body to the external conditions of the investing atmosphere—the enormous influence of meteorological conditions on the mind and body of *homo sapiens*, from the cradle to the grave, are not likely to be overestimated; and give good grounds to the skilled and inquiring observer for arriving at the conclusion that *climate* is, upon the whole, the most important factor in the formation (and maintenance) of *national character*. That the mere elevation of the temperature of the surrounding air is not the great central factor in the development of physiological mischief in the variably torrid season of our uncertain "temperate" climates is well shown by the conditions of contemporary existence in the warm chambers of a Turkish bath. This fact, too, calls emphatic attention to the importance of the cutaneous excretion in regulating the temperature of the human body; and will, I trust, be accepted as an apologetic explanation to the reader for taking the opportunity of dwelling at some length upon some of the underlying physical facts—which probably seldom arrest the attention of the busy general practitioner.

The immense importance of the (relatively watery) cutaneous excretion, as a contributory factor in the regulation of the temperature of the body, depends, in greatest measure, on the physiological utilization of the physical entity known as *latent heat*. This may be defined to be: the heat which is used up in changing the *state* of a body, without changing its *temperature*. Three varieties are generally recognized: latent heat of *fusion*, latent heat of *evaporation*, and latent heat of *expansion*. It is a readily recognizable fact that the various known forms of matter exist in three different (and highly contrasted) "states"; solid, liquid, and gaseous. (It would, of course, be quite a work of supererogation to discuss, on the present occasion, the properties or features—real or fancied, physical or metaphysical—which distinguish the corpuscular, electronic, ionic, radiant, or *ultimately* ethereal conditions of the material constituents of our still somewhat mysterious cosmos.) The fact can be most instructively illustrated, for present purposes, by the very familiar example of *water;* which in the solid state is spoken of as *ice*, and in the gaseous state is popularly referred to as *steam*. In the present generation of universal education and universal suffrage, it is known to the majority of our intelligent voters that the melting of a quantity of ice is a somewhat slow process, which requires the expenditure of a proportionally large quantity of heat; also that no marked elevation of temperature takes place within the contents of the containing vessel from the melting process has commenced till the *quam proxime* completion thereof has been effected. The heat which has thus been expended is known to physicists as the *latent heat of fusion—"latent heat" of water* in this instance—and represents a large quantity, indeed, having regard to the mass of matter employed. If the application of heat to the vessel be now continued, the temperature of the water will continue to rise till the liquid begins to "boil"—that is to say, till the rapid evolution of steam at the bottom and sides of the vessel begins to cause the characteristic bubbling agitation. The temperature then ceases to rise, till the whole of the liquid water has been converted into *gascous steam*—of the same temperature; after which the heating of the "water vapor" can be continued—by the aid of a suitable furnace, and within a suitable vessel—till any desired thermometric level has been attained. Any reader who has ever tried, even in the remote years of mischievous and lawless childhood, to boil off a kettleful of water into steam can hardly ever have been aged into forgetting what an extremely and aggravatingly slow process that experiment proved to be! It impresses the observant mind of the experienced adult, too, by its demonstration of the vast magnitude of the masked calorimetric quantity which is known as the *"latent heat of evaporation"*—in this case, *"latent heat" of steam.* The enormous quanties of (the old-time) "caloric" which are thus secreted—or disguised, or converted—in case of each of the great physical modifications of this most familiar of fluids are, as we shall subsequently see—and, especially in the case of the latter and greater, of *evaporation*—actually in continuous process of utilization by Dame Nature (and thoroughly utilizable by her somewhat clumsy servant, and so often densely unappreciative confidant, Man) in the maintenance of the stereotyped thermometric standard of the surface temperature of the human organism in presence of the immense range presented by the variability of calorific environment—of climate and clothing, of sunshine and shade. The immeasurable importance to the animal economy—and especially in the case of the originally naked human specimen—of the physical properties of the (single) *"element"* to which the first of Greece's "Wise Men" would fain attribute the genetic origin of all cosmic aggregations of

"*matter*" is also largely due to the unique magnitude of its calorimetric storage capacity: the physical property known as "*specific heat.*" This latter is usually defined to be *the quantity of heat required to raise a certain mass* (say 1 lb., or 1 kilo.) *of any substance through a given thermometric range* (for convenience of calculation and of reference, 1° of the scale in use) *compared with that required in the case of water.* The fact that the specific heat of water is *higher than that of any other* known specimen of Nature's manufacture—indeed, so far as I can ascertain at the present moment, is higher than that of any artificial mixture, excepting (*mirabile dictu*) that of alcohol *plus* water (so practically familiar as the genial British "grog"!!)—is, in itself, one of the most protective and adaptable provisions of the profound wisdom of a far-seeing Providence toward safeguarding the physical welfare of the most errant—not to say lawless vagabond—denizens of this planet's surface. And we may now proceed, and, I trust, with some profit, to examine the influence of these factors on the functional fitness of humanity, individually and collectively.

Having placed—permanently and conspicuously—before us the physical fact that water possesses the characteristic endowment of the maximum specific heat known to the scientific explorers of the dark ways of inorganic matter (that the combustion of a larger quantity of fuel is required to raise the temperature of a quart of water through one degree of the chosen thermometric standard than to produce the same calorific modification of the same mass of any other substance), the fact is easily grasped that the general climatic, and the individually physiological effect of the presence or neighborhood of a great body of water (externally), or of a vast number of systematically arranged channels (internally), is to act as a permanently placed "drag" upon the variations of temperature. Compared with the adjacent dry land, and especially the sandy and rocky areas of the same, the ocean warms slowly during the day, and cools with corresponding reluctance during the night. Hence the refreshing "sea breeze" of the sultry summer noonday; or as the cooler air of the layer of atmosphere which was placed in contact with the surface rushes continuously to shore to maintain the internal equilibrium of the aerial ocean—to supply the place of that which is continuously boiling upward in geyser fashion from the roasted surface of the land (while spouting more violently if the surface in question happen to be largely composed of rock or sand). Hence, too, the evening current always displays itself as a "land breeze" in the very opposite direction—so rapidly does the solid crust of earth cool, as compared with the slow devolutionary escape of the cast thermal store which had been laid up—without special exertion—by the investing fluid during "each shining hour" of the past day. And again, hence, when sitting on the rockbound seashore in the immediately postmeridional period of a torrid summer day, one hand is cooled by being dipped in the water while the other is actually scorched by contact with the adjacent rock. And inevitably—and inseparably—associated with these physical (circumterrestrial) phenomena is the genesis of the vast system of aerial currents, which in so very large proportion make and modify the temperature and other climatic conditions of our planet's highly variegated surface. Also, the movements *en masse* of this restless spheroid, on the surface of which we live and move and have our being influence the conditions of temperature under which we are obliged to exist—with more or less painfully struggling effort—in every department and in every particular. The relationship of orbital revolution to seasonal temperature is, of course, far too gross and palpable to sense to call for general discussion before an audience dowered with congenital intelligence and acquired scientific attainment. But that of its diurnal rotation possesses a very important interest, which used to remain very much unrecognized by the man in the street before the halcyon days of our "intermediate"—and universal—education, and the universal suffrage which has been so powerfully instrumental in the eliciting and culturing of universal discussion of all subjects, and among as well as by "all sorts and conditions of *men.*" (I sometimes wonder what will the approaching Babel of science and logic be like during the generation next following the conquest of masculinity by the inspired host of Suffragettes!)

Our heat is all originally derived from the etheral waves which radiate from the sun: even the subsidizing quantity which is enclosed within the contents of the kernel of our globe, as the experts assure us, must be admitted to the same paternity when we have recognized—with retrospective justice—the integrated sum of the claims of all the historic as well as contemporary factors and quantities. Those *luminous* waves—oscillations of the ultimate constituents of the primordial ether—are converted (modified) into "lower grade," and less regular, vibrations as they become entangled in our investing atmosphere; and by collision with the earth's unsympathetic surface materials are subjected to a "degradation of energy," and of type, which may, perhaps, not inaptly be illustrated by the hopping of a racket ball when it has been allowed to reach the smoothly cemented surface of its court, after forcible (parabolic) propulsion from a considerable distance. The energy of the resulting heat waves is disposed of, in a general way: by *conduction* along and near the earth's surface, and by bodies in contact therewith; by *convection*—by the constituent particles of the currents of liquid and gaseous media (water, air, etc.), and by *radiation*—the recoil and diffusion of the modified—and degraded—ethereal waves to the genesis of which a reference has already been made. The intensity of the sun's calorific effects varies with the inclination of the rays of our great diurnal luminary; it is at its maximum when their impact is vertical—as it always is *somewhere* in the tropics—and the direction of the recoil is accordingly coincident with that of the sunbeam, and approaches zero level as a "grazing incidence" is reached with the approach to the pole. Then on account of the facts that: as the ethereal solar waves traverse interplanetary space as *light*, and become transmuted ("degraded") into the more irregular *heat* undulations only after dashing into our circumterrestrial atmosphere, and colliding with and recoiling from the terraqueous surface of the globe itself; and, as air, although a very ready convector, is a very bad conductor of heat (while the ethereal medium which occupies interplanetary space does not seem to function in that way at all), the atmospheric envelope of our globe which displays physical evidence of retention of some solar heat corresponds pretty closely in thickness to the height reached by the recoiling solar waves. Hence the "eternal snow" of

the lofty mountain summits of the intertropical zone of the earth's surface, at the base of which the sun-baked inhabitants are obliged to have recourse to their very best ingenuity to make existence endurable during the hours of solar predominance. Thus does *climate* vary with *latitude* and *altitude*.

Again, as heat is, in the last resort, as we are always being reminded by the experts, merely a mode of motion, and as one of the most obvious as well as one of the most important and far-reaching effects thereof is *expansion* (a rule to which *silver iodide* appears still to remain the solitary, and strangely curious, exception), the making of this molecular "elbowroom" furnishes us with other notable factors and consequences which have to be theoretically considered and otherwise practically dealt with in this connection. On account of the expansive agency in question, the lower layers of the torrefied midday (and especially, of course, midsummer) air of every heat wave—are always "on the climb," while this diffuses itself circumferentially with the gradual ascent—which is also limited in the degree of its altitude by the concomitant processes of cooling and consequent condensation. The cooling effected by passing (upward) into contact and mingling with the air contained in the upper strata of the atmosphere is complicated by the condensation of retained water vapor which restores to the "*sensible*" state the previously *latent* heat of the same. This continuous vertical impulsion of the lower layers of the atmosphere and centrifugal —northerly and southerly—movements of those of the partially cooled strata which have reached the ascension limit (determined by the relative density that is regulated by the cooling and contracting process) characterize the equatorial zone all the year round, and the fact made the belt of *equatorial calms* familiar and fearful (to a degree even greater than the dread of storms) to the adventurous "Tars" of old who ventured to cross "the *line*" on their relatively fragile wooden barks under the mercy of the winds and waves on which alone they relied for propulsion. This general physical effect is, of course, inevitably modified—almost everywhere—by the endless variety of collateral conditions which influence nearly every considerable area of the terraqueous surface of our globe.

Then the suspended aqueous vapor of the atmosphere, which is derived from the water surface of the whole globe, exercises an immense influence in the making and breaking of climate—and its conditions and consequences. It is, I believe, admitted by most visitors that there is no feature in the physiognomy of Ireland so distinctively characteristic (at least to the non-political eye) as that which inspired the original suggestion of its most poetic appellation: the "Emerald Isle." And how much there is, or may be, in a name, or can be implied by an appropriately selected one, can well be exemplified by an examination of the significance of that epithet, and an analysis of the evidence for the appropriateness of its application. The unequaled verdure of our proverbially "*green* Erin" is a physical consequence of the fact that we are evermore under a cloud; a blanket screen of water vapor, which is but seldom completely volatilized, always intervenes between us and the sun. One of the most notable physical results of this atmospheric *plus* aqueous disposition of materials is a leveling of climatic extremes; a very pronounced tendency to moderation of temperature levels. While our physically misty and mentally depressing canopy curtains off the scorching rays of an otherwise possibly scorching sun, and thereby provides a natural protection from sunstroke and sunblisters, it also interrupts, by *absorption*, not only a notable proportion of the direct sun waves which had been trying to reach the earth's surface, but a far larger proportion of the recoil undulations of the radiating rebound—the hopping back of the primordial (corpuscular, ionic, or electronic?) missives (undulatory or translational) which succeeded in passing from the sun's surface to the bottom of our atmospheric ocean. Thus our moisture-laden—too often misty or clouded; too seldom quite translucent, if usually temperate—atmosphere forms a kind of intermediate storehouse of solar heat. For (in addition to the relatively small quantity of calorific energy which is applied to the raising of the temperature of its essential gaseous constituents) an enormous proportion of circumterrestrial heat is actually stored up, in the "latent" form of that "of evaporation," in the *invisible* water vapor which is suspended in the oxynitrogenous ocean whose fluid contents we breathe. And, as the minute droplets of our clouds and mists are ever so very ready and so very much in evidential preparation to intercept ("absorb," "render *latent*") a large *quantum* of the solar radiations (or the recoil waves therefrom derived), the *water vapor strata* of our all too temperate atmosphere actually function as a warm—if much too frequently "wet"—*blanket* cover in the conservation of the solar heat supply. (This function is further complicated by the restoration to the *sensible* type of the *latent* heat of water vapor in the reconverting process of *condensation*.) For the blanket is well known to the physical expert, if not exactly to the omniscient "man in the street," to owe its apparent warmth to *conservation*—and *not* to *generation*. It adds nothing to the heat of the living body which it covers, but it prevents the loss, by too rapid escape, of that which is being continuously produced by the living organism. And it owes this characteristic functional accomplishment to the natural tortuosity of the woolen fibers of which it is composed—which absolutely prohibits their arrangement in parallel lines and planes or in dense strata. Thus all woolen textures carry within them large quantities of imprisoned *air*, which is the *non-conducting* medium that walls in the body heat as it radiates from the surface. So that the lazy Irishman who was lounging along the roadside on a scorching summer day in a heavy frieze coat (his only untattered garment), and when asked, by a three-quarters naked acquaintance, was he not "railly out ow" his "latitude to be wearin' sich a load o' wool ow a day like this," promptly retorted (in Hibernian fashion) with the counter-query: "Sure doan't you know that what keeps out the cowld keeps out the hate as well," was actually endowed with a fund of "physical" *inspiration* (as it would seem to have been) of far greater magnitude and more penetrating and enlightening quality than he would have ever suspected for himself.

And as all items of information on this subject must possess a definite interest in the light of the experience (and after the swelter) of recent atmospheric and solar conditions, I will just embrace the opportunity of pointing out in passing that the conspicuous value of *silk* in the texture of *woven* garments is due to the non-conductivity of its fibers which holds in this case in relationship to *heat* as well as to *electricity*, as is the general rule. Thus

it offers a direct and interesting contrast in the passive exercise of this practically useful accomplishment, to the correspondingly utilizable thermal qualities of *wool,* which are simply based upon the physical fact that every fiber of the natural overcoat of *ovis aries* is a miniature corkscrew, or in Hibernian phraseology, something "aiquilly worse" in the matter of axial rectitude, and accordingly in the hands of the weaver it inevitably is made to help to construct billions of somewhat leaky air prisons, which, when adapted in series, to the surface of the human body "keep out the cold" simply by keeping in the heat. Heavy articles of clothing, it may be appropriately noted here, necessarily cause increase of heat production by the mere muscular exertion which is expended in carrying them about. It will be remembered in this connection that muscular tissue is the great central furnace of the human (the vertebrate) body. Also it is found that non-porous, waterproof, and the various allied articles of clothing are specially objectionable in hot weather; the reason is that they obstruct the free circulation of air—which is the most efficient aid in the promotion of evaporation by the continuous current of a fresh supply that conveys away the water vapor as rapidly as formed and before the clogging condition of *saturation* can have an opportunity of manifesting itself. The importance of this factor is due to the gradual diminution of the rate of evaporation of the water which lies beneath an immobile stratum of air; when the latter becomes "saturated," evaporation in the ordinary (the *visible*) sense of the term must cease, however actively the molecular and ionic interchanges may continue to proceed at the surface of contact of liquid and gas. And this, in turn, to the physical possibilities attached to the *latent heat of evaporation,* which accounts for the dispersion of quantities of "caloric" relatively so enormous—when considered in connection with the quantities of liquid concerned. Thus it is that we can understand, too, why the light and porous articles of dress—those which favor the free circulation of air—prove so desirably refreshing in warm weather; they promote the utilization of the *latent heat* which Nature continuously employs for the physical dispersion of the physiological surface supply.

Thus it becomes apparent that "latent heat" is the most continuously important—even indispensable—of the physical agencies by which the relationship of animate to inanimate matter is continuously controlled in accordance with the universal plans and laws of the all-regulating power which presides over the whole. It even proves to be the most important agent through the intervention of which external influences can be brought to bear upon the functional activities of the great collective governing powers that are located in the neuronic systems of the central cerebrospinal axis. It is through its physical capabilities, and the adaptation thereof, that man has been enabled to prove himself the unique specimen of organic life which has displayed something of approximate attainment to cosmopolitan climatic adaptability. The skilled control of latency of heat over the surface of the naturally naked human body was even more essential to Commander Peary's attainment of the North Pole than were those truly heaven-sent raindrops in preparing Benjamin Franklin's kite string to conduct the lightning from the thundercloud to earth and dethrone forever the demoniac "Prince of the Powers of the Air"; while simultaneously wrecking, and by the irreparable process of startling (and so often depressing) disillusion, the terrorizing dignity which had been thereunto attached by the creative imagination of *homo sapiens,* down through the whole period represented by the annals—traditional and transcribed—of recorded time.

The comparative unfamiliarity—to use a clumsily mild phrase—of even the more intelligent and "well read" citizen with the important influence on the human organism of the physical factors above referred to, both in health and disease, is perhaps due (in great measure at least) to the fact that heat has evermore been looked at askance with an oblique superficiality by the inquisitive amateur as probably the nastiest of all the sciences that he has at any time endeavored to assimilate. But surely in the present stage of the rectilinear progress and circumferential, if not even centrifugal, diffusion of physical knowledge and the application of the same to human health and human comfort there is all the more reason that the laws and facts of one of the most important and still curiously mysterious as well as interesting of the vital phenomena which characterize the highest types of animal life (while displaying surface facets of intimate contact with the properties possessed by inorganic matter) should be at least peptonized, if not perfectly pasteurized, for universal circulation, digestion, and permanent assimilation by the members of a profession the validity of whose practice and the safety of whose clients depend largely on a thoroughly firm intellectual grasp of the same. The deficiency of the more than desirable degree of proficiency in the department of knowledge referred to is far too often conspicuous even in the contents of those columns of our medical journals which are occupied by the contributions of physicians of authoritative—alas! too often "professorial"—positions Even the leading representative journal of British physical science yielded space, in the past year (!), to a discussion of the special accomplishment of Æsop's hero, who *blew hot and cold with the same mouth,* in terms which seemed to send a cold shiver down the intellectual backbone of the present writer—and certainly suggested that the general *latency* of "latent heat" (the indulgent reader will, I trust, tolerate the passing play of words), to the mind's eye of even the amateur scientist, is one of the most epidemic of the defects of cerebral equipment in the present day. Accordingly, the fact can hardly be overemphasized that the *misdirection* of latent heat—whether by the error of the conditions imposed by inevitable Nature, or that of misguiding man—is *the* great cause of *chill;* which is, in turn, the great cause of *inflammation;* which, again, is the *foundation of each of the commonest ailments of the human body*—and is, accordingly, by far the *most frequent cause of disease,* both acute and chronic, and of *death* itself! Thus, if the influences of latent heat were duly controlled and rectified, at least three-fourths of the microbes which prey so prosperously on the weakened tissues of humanity would be hopelessly consigned to the ranks of the "unemployed"!! And, even in the best regulated families, and among the best behaved individuals, the phenomena of latent heat, and the laws which govern the same, influence the surface temperature more than do any other. The "latent heat of *fusion*" need not be further discussed in this connection. But the "latent heat of *evapora-*

tion" not merely represents the expenditure of a vast quantity of heat (and valuable coal or other combustible matter) in the conversion of liquid water into gaseous (over the kitchen fire); it is, as I have repeatedly indicated, accountable—in greatest proportion—for keeping down the surface temperature of the human body to the normal standard of health; and—more startlingly serious—it is accountable for nearly all of the items of the perpetually evolving catalogue of the deadly chills that develop during rest after copious perspiration or drenching by rain. Evaporation of the layer of watery fluid which lies on the skin is, of course, promoted by the warmth of the latter. And the enormous quantity of heat which is consumed in the process is *drawn off* from the inner store which is supplied by the medium of the circulating arterial blood as it courses continuously toward the surface. The evaporation proceeds more rapidly, as above explained, when the stratum of air which lies in contact with the surface is continuously renewed, so as to prevent any approach to *saturation*. And for this reason it is that a sudden (so often deadly!) chill takes place when exposed to an air draught, seated in a damped skin—whether by perspiration, rain water, or other *fresh* water. The importance of the term "fresh"—on that account purposely italicized—is, I fell pretty sure, practically known (as a result of personal experience) to the vast majority of readers. But I incline to be at least correspondingly confident that the theoretic explanation of the familiar physical fact that one feels more chilly after a freshwater bath than after emerging from the seawater plunge could be supplied offhand by the members of the minority only. After the freshwater dip the latent heat of evaporation exercises its usual influence—modified by the conduct of the individual, and the coexisting conditions of environment. After emergence from the fluid embraces of Father Neptune the *latent heat of fusion* of the saline compounds held in solution in the seawater is restored in *"sensible"* form, on return of the various items to the solid (crystalline) state; and, as we all have in our respective turns felt, with consequences quite delectable to the human frame. The billions of crystals which form on the skin after a saltwater bath prove so many microscopic fires, which go collectively to the formation of a soothingly hygienic edition of the mythological shirt of Nessus! Hence the blissful *glow!*—while after emergence from fresh water the latent heat of evaporation never fails to supply the necessary—*negative*—conditions and influences for the genesis of chill. And before dismissing the subject of this special physical agency, and its influence—continuous and paroxysmal, "tonic" and "clonic"—on the temperature, directly ("immediately") on the surface, and indirectly ("mediately") on that of the whole interior of the organism I will just take the opportunity of calling the reader's attention to the evidence of the importance of the influence of the water vapor of the atmosphere as a regulator of temperature which is furnished by the authentic records of the phenomenally high temperatures which the human frame can tolerate when the air is perfectly dry. The rapid "boiling off" of the perspiration from the whole cutaneous surface renders "latent" quantities of heat so enormous as to maintain the body temperature at its normal standard level. (*Saturation* of the surrounding atmosphere with water vapor under such conditions would generate the duplex calorific horror of preventing the escape of the body heat by the surface, while introducing the prospect of being cooked in a dilute watery medium!) Also would I remind her or him that the luxurious escape from the suffocating surroundings and conditions of a torrid summer's day (especially one of central urban existence) into the delightfully cool sea water is one of the physical experiences which is, I believe, universally rated among the most delightful; graced, as it is, on both aspects, by hastening anticipation, and by recollections of past enjoyment. And the unique possibilities of this delectable item of compensatory luxury are definitely based upon and provided by the great *specific heat* of water. Fortunate, indeed, is suffering humanity in this one fact at least of its physical environment—that water is so much less easily heated than fixed land, and than mobile air.

This same physical quality of the high (highest) specific heat of water, which accounts for the almost startling contrast of the scorching temperature of the seashore rock with that of the refreshingly cool water which ripples and eddies by it, in its eternal ebb and flow, is also accountable for the genesis of the vast circumterrestrial phenomena of the "land breeze" and "sea breeze" (and influences the geometrical precision of the limiting borders of the "trade winds"; and for the production of the generally familiar atmospheric phenomena of *cyclonic* depression, and *anticyclonic* elevation of the average weight of the superincumbent column of the atmospheric ocean at the bottom of which we breathe. The general tendency of atmospheric movement in the vicinity of the equator is, as we have seen, to the primary vertical, and secondary horizontal; the latter being directed at right angles to the original plane of projection—in response to the respective necessities of expansion and gravitational equilibrium. When this latter condition has been approximately restored and the upper air current has reached a degree of *latitude* of which the frigorific conditions combine with those of atmospheric *altitude* to produce a degree of condensation sufficient to cause a tilt of the gravitational balance in the opposite direction, the result is a tendency to a vertical downward current, to the influence of which is due the development of the meteorological phenomenon of the *tropical calms*. And, at the foot of this latter partition wall of aerial movement, the same physical laws determine the production of diverging—centrifugal—tidal movements; one, a return current directed toward the equator, which is determined by the diastolic suction of lower pressure in that direction, and is continuously utilized in the maintenance of the ever mobile equilibrium; another directed toward the poles, which owes its primordial genesis to the *vis a tergo*. And so on—with the endless variety of local modification imposed by the inexorable conditions derivable from the physiognomy of subjacent Mother Earth. The irregular distribution of land and water, of the solid and liquid, the rough and the smooth, the smiles and the tears, the rotundities and the wrinkles on the face of our *alma mater* combine with the obliquity of her axis and the eccentricity of her orbit to give our apparently lawless atmosphere the inscrutable uncertainty which the (semi-) inspired pagans of old made symbolically incarnate as Ἥρα or Juno. In the absence of the hopelessly entangled complexities of physical phenomena presented by every zone and section of the terraqueous surface of our planet, the climatic conditions for the year, as well as for

the day, could be predicted with the same confidence as the result of a well-known laboratory experiment in physics. As it is, the nearest approach to clock-work regularity of atmospheric activity is to be found in the interesting example of the "trade-winds." And their genesis is as understandable as a natural phenomenon can well be made in presence of the facts referred to. The *return currents* which tend to restore equilibrium on either side of the belt of *equatorial calms* have their directions modified by the diurnal rotation of our globe on its axis. The world as it spins around carries its air mantle with it, but not exactly with its own surface velocity; the heavier nucleus is always slipping away from beneath the superimposed gaseous investment—thus providing the latter with a wholly factitious movement of its own in the opposite direction. The combined effect is the genesis of a "resultant" current with the oblique direction of geometric regularity and prophetic reliability which was so familiar and so important to those who went down into tropical seas in ships during the generations which preceded the invention of the steam engine.

Then, not only does the resultant direction of component aerial impulsions determine the orientation of currents under conditions comparatively uniform, as in the case of those supplied by the vast oceanic areas of the intertropical zones; it governs the movements of the local—so often startlingly irregular—eddies which move with the great oceanic matrix in which they were generated and continue to lie imbedded, the great as well as the little; the vast (and oft far too violent) cyclone, and the much vaster anticyclone. It is the knowledge of the fact that our own (so usually) moisture-logged currents and "systems" are "derived," with a fairly definite degree of regularity, from the Atlantic surface, with a general southwest to northeast trend; that our broad cyclones and still broader anticyclones are conveyed bodily along the same lines of traction as those which so lightly and gaily convey the local gusts and eddying breezes—it is this physically utilizable and mentally gratifying fact that has made our system of *weather* soothsaying provisionally possible, if not always quite satisfactorily prophetic. And it is surely one of the most characteristic triumphs of the practical American mind—and its methods—that it has made the present system of aerial prophecy the conspicuous feature of physical science that it now is.

With so many various—and all too readily variable, and almost continually varying—influences at work on our slippery atmosphere there is no reason for surprise at the fact that weather should be one of the most kaleidoscopic of physical entities. Not only the great cosmic physical laws and factors to which I have referred at some length, but every sunspot, every wobble of the earth's axis, every great cosmic disturbance (even the unseen, the unheard, and the unfelt); thermal or ethereal; luminous, magnetic, electric, electronic or ionic—as well as the still mysterious physical conditions of the interior of our globe, has its individual effective influence on our atmospheric phenomena and the weather which is created (and connoted) by the same. Every schoolboy knew—even before the luminosity of intermediate education penetrated our atmosphere—that our seasonal summer heat was given us by the more direct (less oblique) incidence of the solar rays at this season in presence of the fact that the great calorific focus occupies a considerably more remote position. And, if all physical conditions remained steady, the heat of July and early August would always be greater than that of the solstitial June days and for the same reason that the hottest time of day is toward 2 P. M.—that the heat which has been absorbed by earth, water, and air has been in part retained, and is accordingly added to that which continues to be supplied by the solar radiation which has declined in relatively smaller proportion. Such would be our estival experience of every annual cycle—in the absence of that almighty IF!

I have dwelt with reiterative emphasis on the enormous influence on temperature of the two physical properties of water, in each of which that familiar fluid displays an opulence that is practically unique: *specific heat* and *latent heat of evaporation.* The former acts as a permanent drag on the thermic variations of the atmosphere and of the adjacent limiting land borders; the latter as a leveling standard regulator of the temperatures of the surface (and less directly of the whole interior) of the human body. The stages by which those illuminating items of thermal science were brought to their present state of faceted brilliancy made the landmarks of a tedious and tortuous and inevitably thorny pilgrim's pathway—every forward stride on which was faced by obstruction flanked by contradiction and pursued by detraction. Not a rare feature, it must be added, in the biographical record of the "advancement of learning" and science! And to some of us who have had special opportunities of seeing and hearing such artists at work at their natural callings of prevention of progress and enlightenment and soiling of superior reputations it must ever remain a peculiar pleasure to render, whenever possible, even a contributory mite of justice to the philanthropic genius of science whose enthusiastic devotion has made the human race richer and happier in the best sense of each of these terms. All tyros in the history of physiological chemistry are, of course, aware that the solid bedrock on which our knowledge of animal heat has since been erected was first laid bare by the founder of physiological chemistry, the illustrious scientific martyr of the "leveling" principles of the great French Revolution. It was indeed, in the opening year of that unique political cataclysm that Lavoisier formulated his theory of animal heat in the following terms:

"La machine animale est principalement gouvernée par trois régulateurs principaux: la *respiration*, qui consomme de l'hydrogène et du carbone et qui fournit du *calorique;* la *transpiration,* qui augmente ou diminue suivant qu'il est necessaire d'emporter plus ou moins de calorique; enfin, la *digestion,* qui rend au sang ce qu'il perd par la *respiration* et la *transpiration.*"

The physiological horizon of that great pioneer was, very necessarily, limited by the very defective luminosity of the twilight dawn of the period, but, having regard to his environment, the brilliancy of his intuitive conception and the crystalline lucidity of his expression of the same, shine out all the more clearly in the retrospective view of the skilled observer. The subject, peculiarly entangled as it is in the complexity of its associations, and faceted on every aspect by its innumerable impressions of contact with the problems of living and non-living matter, is one specially appropriate to the display of the relative strength and weakness of the intellectual powers and attainments of those who

grappled with it in public for the edification of their contemporaries and of posterity. A few selected examples in illustration of this fact cannot fail, I think, to interest the inquiring reader. The illustrious Boerhaave, who held the highest reputation among the medical giants of his generation in all the intellectual attainments ancillary to the science and art of the physician, believed that the higher animals could not exist in a medium of temperature equal to much less higher than their own. His opinion is expressed with all confidence: "Observatio docet nullum animal quod pulmones habet posse in aere vivere cujus eaden est temperies cum suo sanguine." (The ruling idea there was, very evidently, that one of the great uses of the inspired air to the animal economy was the *cooling of the blood.*) Indeed, the first great physiological pioneer who put forth his best powers in the refutation of that view was the encyclopedic scientist, Albrecht Haller, who devotes no less than seven pages of his great work to that highly meritorious task and concludes in these terms: "Ex his ergo omnibus comparitis conficitur, canguinem quidem ex recepta opinione pluramque atmosphera calidiorem esse, in qua vivitur: sed etiam in eo aere vivi posse, qui supra summum sanguinis calorem *sedecim gradibus* calescat et ultra." And the epoch-making series of experiments on the tolerance of high temperatures of the surrounding air which were carried out in 1775 by Blagden, Fordyce, Banks, Sorander, and Dobson are said to have been originally suggested to Blagden by an ideal specimen of cryptic Caledonian wisdom which he had heard enunciated by Professor Cullen (of nosological fame): that certain of the higher animals were endowed with a faculty of *producing cold* under special crucial circumstances. (So that this specimen of scientific inspiration was actually fraught with results comparable to those of the best illumination of North British *second sight!*) And when Blagden demonstrated that he was able to bear a temperature of 128° C. in a dry oven for eight minutes and a supplemental exposure to 110° C. during twelve minutes, the classical theory was finally displaced by the convincing results of modern experiment!

But while that new light and the source thereof are generally familiar to the expert British reader, the fact is seldom emphasized in English scientific records that, in spite of the criticisms of Haller, the opinion of Boerhaave held conservative sway till the communication by Tillet to the *Académie des Sciences* of Paris of the results of his researches "Sur les degrés extraordinaires de chaleur auxquelles les hommes et les animaux peuvent resister." In company with Duhamel, he had (in 1760) had an opportunity of observing that "trois jeunes filles, attachées au service four banal de Larochefoucault pouvaient rester cinq et même *dix* minutes dans l'interieur de ce four, quoiqu'il fut encore assez chaud pour cuire de la viande et des pommes." Thermometric measurement showed that a ten-minute exposure to a temperature of 132° C. was borne without inconvenience; while a closely corresponding tolerance was displayed for "pendant cinq minutes, une température *supérieure de quelques degrés* à la precedente." His "Memoire," which was published in 1763, contained the results of a long series of experiments on the endurance of high temperatures by dogs, cats, rabbits, and birds. And far more remarkable, having regard to dates and circumstances, and infinitely more instructive in the arrangement of demonstrative facts and the deductions therefrom derivable, are the results of a series of investigations which were communicated, in 1758, to his friend Dr. Linning of Charlestown by the amateur pioneer of science and philanthropic champion of liberty and justice, well-being, and well-doing, Benjamin Franklin. In dealing with the question of evaporation and its refreshing effects, he explains:

1. Why, within a room in which his body was covered with sweat and wearing but a shirt and linen drawers, his temperature remained continuously below that of the air, which registered 37.78° C. in the shade. 2. Why the harvestmen of Pennsylvania, while at their work and exposed to the direct rays of a bright and burning sun, were not incommoded by the heat so long as they continued to sweat profusely, while they rapidly succumbed if the sweating ceased; and, accordingly drank copiously of a beverage formed of a mixture of *rum and water* with the object of keeping up the process of perspiration. 3. The custom of venerable use among sailors of holding above the head a finger moistened with saliva in order to ascertain the direction of the wind by observing on which side it felt coolest. 4. The resistance offered by young shoots of trees to the scorching effects of the sun's rays. 5. The use of the fan as a means of refreshment. 6. The use of compresses soaked in spirit of wine for the relief of parts affected by acute inflammation in preference to linen cloths moistened with water, which evaporates less readily.

Thus he displays and reveals for the benefit of humanity one of the most important (as well as remarkable and otherwise interesting) series of observations and conclusions that has ever been made and elucidated by any one scientist or physiologist, whether expert or amateur. The extraordinary keenness of observation and almost inspired clearness of mental vision, by which he was able to look internally for theoretical explanation and externally for practical application, in the very best interests of humanity, too, show Franklin to have been here, as in so many other departments of science as well as of politics, one of the most gifted and earnest, and ultimately useful, of the guides and prophets who have so long been leading erring humanity to the promised land of perfection of human spiritual wisdom and material comfort. And here I cannot refrain from calling the reader's passing attention to the startling contrast which is presented in this connection between the views and the practical applications thereof of the Philadelphian journeyman printer and self-taught amateur scientist and those of the Caledonian army surgeon and physiological expert, of whose loudly trumpeted "discoveries" and collateral scientific performances and teachings every unfortunate British medical student is doomed to hear so much during the hardworked sessions of his heavily weighted *Lehrjahre.* While admitting that each organ and portion of the human body possessed the *faculty* of heat production, John Hunter considered that there was a great primordial source of animal warmth and concluded that "it is probable that this principle resides in the *stomach.*" (Sound Scotch materialism—or was it an echo of the view of the famous iatrochemical mystic, Van Helmont, whose hypothesis located the human *soul in* the *antrum pylori?*) And that redoubtable apostle of *inflammation* and the mysteries thereof credited the *vital forces* with the *faculty* of annihilating a certain proportion of the animal heat in maintaining the prescribed normal standard of temperature!

Allusion to the views of the "Father of Electricity" on latent heat reminds me of the fact that there are as good grounds for recognizing Benjamin Franklin as the *Father of the Gulf Stream,* too. For it was he who laid the foundation of its physics, and he transmitted the living product to posterity dowered with the healthy constitution which was inherited by every member of his scientific offspring. But the *nimia diligentia* of a nursing and pampering posterity led to its development into a mythological monster! Thoroughly characteristic of that extraordinary genius and enthusiastic scientist, the indefatigable journeyman printer, self-taught philosopher, devoted philanthropist, and inspired, as well as patriotic, statesmen is the fact that in the April of 1775 on his return voyage from London to Philadelphia on which he had been obliged to embark hurriedly in order to secure his personal safety after having received the most ruffianly insults from his aristocratic superiors of the mother country when attempting to negotiate the rights which had been claimed by the New England colonists to a share in the management of their own taxation; that man, whose past period of earthly pilgrimage had then come closely to approach the hagiographical limit of three score years and ten, was seen hour after hour daily on the margin of the deck of his homeward bound vessel taking the temperature of the air and then dipping his thermometer in the Atlantic, and scanning the record of the rise or fall on withdrawal, as eagerly as if no other object of earthly interest specially concerned him at the time. (And equally characteristic is the fact that he had then with him on board his *first* velvet *"court suit,"* that he had worn on the special occasion on which he was admitted to the presence of the English ministers in his functional capacity of representative of the New England colonists and advocate of their political rights; and from which he was soon ejected with gross insult as a mere mechanic. That suit was then carefully laid aside, to be next assumed after an interval of eleven years, when the wearer, as Minister Plenipotentiary of the newly inaugurated Republic of the United States, attended in Paris to witness in his then *inviolable* capacity the signatures of the same English ministers to Great Britain's documentary recognition of the independence of the newborn and fullgrown Pallas of the nations, whose wisest citizen had served her so long, so devotedly, so stainlessly, and so successfully!) On the voyage referred to Benjamin Franklin gave the first practical demonstration of the fact that the thermometer could be utilized for the purpose of determining the relationship of the voyager to the Gulf Stream, and thereby defining the longitude, which was more often guessed at than measured in those days, and an exact knowledge of which was of comforting importance at a date when a transatlantic excursion occupied a diurnal space of some six to nine weeks. But it must be noted here, as we pass, that fully five years before the same observer prepared and had engraved for the prospective enlightenment of all future Anglo-American navigators *the first chart of the Gulf Stream.* At the same time he laid down the view that the permanent *trade winds* were the initial factor in the production of the Gulf Stream; and though partly erring in the details of his hypothesis he was right in believing that the aerial circulation over the surface of the North Atlantic is the dominating agency in the development of the aqueous surface drift. And his theory regarding the action of winds in the genesis of ocean currents has been fully borne out by modern hydrographic research. But when he arrived in Philadelphia he found that the battle of Lexington had already passed into history and he proceeded to suppress his charts as effectively as he could so that they might not be utilized by the enemy during the war—or after! The net result, so far as the much libeled Gulf Stream *drift* is concerned, was that no further detailed discussion of the subject was presented to the scientific world till the appearance of Maury's "Physical Geography of the Sea" in 1855. This author made the existence of the Gulf Stream an argument in proof of "design in the physical world." And he opens his volume with a thrill quite dramatic in its effectiveness: "There is a river in the ocean." (!) This "stream" he described with fantastic vividness of conception as "a sheet of warm water said to be more than three thousand times greater than the Mississippi River," which was transmitted "entirely across the Atlantic Ocean." He proceeded to compare its effects on the climate of the British Isles to the heating of a house in winter by the circulation of hot water, and informed his readers—without a shadow of hesitating doubt—that "one of the benign offices of the Gulf Stream is to carry heat from the Gulf of Mexico, where otherwise it would become excessive, and to disperse it in regions beyond the Atlantic for the amelioration of the climate of the British Isles and of all western Europe." He maintained that "winds had little to do with aqueous currents" and in accordance with that view totally contradicted the notion advocated by Franklin that the trade winds originated the Gulf Stream at all, either wholly or partly.

Such was the teaching which caught the eye and proceeded to hold the ear of the whole civilized world and is still taken seriously by a very large proportion of its "intelligent and educated" citizens! This, too, in presence of the fact that a good many years ago one of the most accomplished of living meteorologists, Mr. Henry Maitland Watts, pointed out to the reading world in a popular scientific article: "that the belief that the Gulf Stream is the sole cause of the mild oceanic climate of western Europe is still held by millions to-day, that it is still taught in public schools in England and in the United States, and that, although it is absolutely without any foundation whatsoever, it should come to have all the sacredness of a gospel truth is a tribute to its attractive statement by one man and the hypnotic influence of one book. . . . In consequence the 'Gulf Stream myth,' fathered by Maury, persists, while the broader, grander, and more reassuring facts as to climate and weather causation are viewed with suspicion, and make slight headway against the universal acceptance of a theory that gained its whole value from the way it was stated by a strong man in the transition period in the development of an inexact science. The essential facts are that the Gulf Stream as an ocean current ceases to exist, that is, to differ in set and temperature from the rest of the ocean, east of the longitude of Cape Race, Newfoundland."

In presence of knowledge which is so readily and universally available, it is surely time that all medical readers had thoroughly grasped the fact that the "Gulf Stream *drift*" does not and cannot convey a *river* of warm water to the shores of western Europe, there to modify the climate and give to the British Isles the breezes of the "unvexed Bermudas," and to Sweden and Norway the soothing sunny

warmth of the Carolinas. The meteorologist who is duly conversant with the fundamental data on which his scientific specialty is now based well knows that causation of climate is not a function of oceanic currents, but of aerial; and easily grasps the fact that the mild oceanic climate of western Europe is due to the distribution of the permanent aerial circulation over the great Atlantic basin, taken with the moderating effects of the proximity of the great ocean reservoir, as a whole. This "permanent circulation" takes the form of a great cyclone in high latitudes, and of an enormous anticyclonic eddy in mid-latitudes. Thus it is to the great mid-Atlantic anticyclone that must, in scientific fact and justice, now be transferred the generative nucleus of the superlative climatic credit that has been so unrighteously retained for so many years by that mythical "river in the ocean," the Gulf Stream. Let us now note the important complemental fact that in the temperate zone the atmospheric drift tends generally from west to east; which means that all coasts and countries lying to eastward of great ocean surfaces possess climates decidedly tempered and ameliorated by oceanic influences; while the eastern borders of large masses of land have their climates very distinctly affected by the extent of the areas of the earth's surface over which the aerial currents have traveled, and we are in possession of the key which unlocks the whole climatic mystery. The great anticyclone which so effectively controls the climate of the bordering countries of western Europe practically covers the mid-Atlantic basin. Its pressure increases in summer and diminishes in winter. And the necessity, already referred to, of its continuous translation in a direction north and east determines the luxuriant mildness, somewhat too frequently over-diluted with moisture, I must regretfully add, of the enviable climate of the British Isles; also, the overruling aerial influence which gives Ireland the distinctive emerald surface tint that haunts the dreams of every "exile of Erin" during the rest of his earthly pilgrimage. The conditions, desirable as they may appear at first sight, are found, as in the case of most experiences of sublunar blessings, to be fairly balanced by the counterweighing drawbacks.

The curious fact in the history of the Gulf Stream myth, as it passes before our mental scrutiny at present date, and exposed to the ample revelations already alluded to, with the glare of the scientific searchlights which were ignited thereby, is that it is still seriously accepted (with more or less critical discussion) by many of the presumably leading authorities, and in the highest class textbooks and journals of physical science. Thus we find a professor of geography at one of the most celebrated of the French universities accepting the mythical stream, and with all the *impedimenta* of its imaginary functions. Our surprise is diminished, indeed, when we come to find the summary of the evidence which the distinguished author found convincing. The direction and velocity of a current have been calculated by observing its effects on the real positions of ships at definite dates—by contrasting the same with those which had been forecasted without taking account of its existence. After consideration of which we learn that: "Elles sont insuffisantes dans le cas ou les courants sont peu rapides et changeants. L'usage des flotteurs permet une évaluation plus precise. Des bouteilles, renfermant une notice sur le lieu et le jour de leur lancement, sont recueilles lorsqu'elles atterrissent, et indiquent le sens et la vitesse moyenne de leur translation. On a pu ainsi démontrer la fausseté des idées admise pendant longtemps sur la circulation dans le golfe de Gascogne, et vérifier l'existence d'un circuit fermé de courants dans le bassin de l'Atlantique. Mais le seul procédé vraiment précis est celui des flotteurs de dimensions assez considérables. Lancés dans une mer assez fréquentée, ces flotteurs ont chance d'être reprénè et observés jour par jour." The writer adds then in a tone of disappointment: "L'operation est malgré tout difficile et hasardeuse; il y a encore peu d'exemples." (As if the *wind* took care to pass by those floating bottles and buoys without physical interference, in deference to the scientific wishes of the geniuses who launched them!!!) Then again in *Nature* July 14 of last year the physical journal which specially reflects the light of the *Royal Society* (London), the topics of this current and its influence on the weather are discussed with all seriousness by a leading meteorological expert. And after oscillating around the center of gravity of his subject this *authority* solemnly suggests: "It seems probable therefore that the Gulf Stream drift, owing to its inertia and its great heat capacity, should have a similar effect to that of the flywheel of an engine, and tend to obliterate the disturbances due to the more unstable and variable atmospheric circulation." After treading one's way through the ponderous nonsense of this article, it is, at least emotionally, refreshing to return to contemplate the childlike faith and reason of the French professor whose Gulf Stream lore and logic recall so vividly the poetic version of the navigational feats of the pearly *Nautilus*, which I used to read with such thrilling interest in my schoolboy days! The only gleam of lightsome hope that meanders through the recorded views of the Anglo-Saxon contemporary authority from whom I have just quoted is that he refers each time to the entity in question as the "Gulf Stream *drift*" (italics mine)! Thus are very vividly illustrated some of the surviving defects of the human understanding—standing forth in the foremost rank of intellectual progress, as generally recognized and appreciated.

Before concluding a communication already, I fear, tediously prolonged, I must ask the favor of the indulgent reader's attention to another calorific or rather frigorific item which has proved productive of a rich crop of nonsensical thermal opinions, "uttered or unexpressed." I allude to the *latent heat of expansion* which seems to have inspired comparatively little popular discussion, in spite of the fact that its influence is even more readily and familiarly demonstrable than that of either of the two other types of latent heat to which I have already called attention—to one indeed, at some length, on account of its continuous importance in physiology, and its unrivaled *productive* powers in the wonderland of pathology. For it is the special physical entity by the agency of which each of us is able, like Æsop's hero, "to blow hot and cold with the same mouth." Every human being attains, I believe (and without special training), to the highly characteristic human accomplishment of blowing cold with (from) a warm mouth—that is, through a whistling orifice. The fact seems to have escaped general knowledge that, although the steam escaping from the pipe of the ordinary boiling kettle is productive of caustic effects—even to degrees of high clinical and pathological importance—when admitted to imprudently close quarters, as so many inquisitive young people discover for themselves before having arrived at the

first climacteric milestone of secondary dental discretion, the "*superheated* steam" which escapes from a correspondingly small orifice in the circumference of a *Papin's digester* will *not* scald although the internal temperature has been actually one, or even two, hundred degrees above that of ordinary boiling water and its steam. This important physical fact will, by itself, account for the uniquely innocuous clinical record of *atmocausis*—a procedure so dear to the hearts and speeches, written and articulate, of so many operative (and otherwise enterprising) gynecologists—even while the appalling dignity of its etymology would seem to rank it with *appendicostomy* in practice, and with the *opsonic index* in theory! The physical anomaly, as it must ever appear to the uninitiated to be, is, of course, due to the instantaneous dissipation of motile energy which results from the rapid escape of imprisoned molecules into a relatively free—almost vacuous—space.

In taking a parting backward glance at the vast field of scientific and clinical thought which has been thus indicated in the course of the present communication and which can be profitably cultivated only after a reliable mastery of the various subjects and viewpoints imperfectly discussed therein, the writer can only dare to entertain a faint hope that he may have succeeded in "raising a spirit" of general investigation—which may tend, progressively, to contribute to the further general illumination of a series of (practically) most important and (theoretically) most intricate topics and problems. I trust that I have included in the usually limited compass of a single (although the reader must have been provoked into calling it a tediously prolonged) article items of important information and authoritative reference which may stimulate the scientific physician to further research. I have endeavored to do passing justice to the memory of the world's greatest scientific benefactors, to the (necessarily very short) list of which young America has contributed so conspicuously. The fact that the summer of this year has made a record in *solar* fatalities and thermal oppression encouraged me to discuss the subjects of *heats* and *chills,* of *heat-strokes* and *light-strokes* and *sun-strokes,* in the hospitable columns of its leading medical journal. Every American citizen must have had the importance of selected attire impressed on his memory by personal experience —of the white raiment from which the light rays rebound; and also the value of the imprisoned air of certain porous and fluffy garments, and of the all-important bi-mural headgear. And similarly for the cold season of trial, the genesis of chill—on which some peculiarly opaque illumination has recently been thrown in British medical literature. The moderating drag of the presence of the great bodies of water interests every intelligent man in the street at present date, even when not hourly called upon to analyze, as we are in Ireland, the factors of our blankety, enervating, moisture-laded atmosphere. I trust that some readers at least, will now have formed a clearer idea of what the *Gulf Stream "drift"* is not, and realized more definitely the honor due to the memory of the "Father of the Gulf Stream." And, to indulge in a moment's aerial flight in closing, I will just remind my transatlantic readers that the fact has been observed that in their great commonwealth a series of droughty years is always followed by a financial crisis (1837, 1873, 1893), even by political revolutions, local and general; while one of Europe's economic sages has pointed out that variations of customhouse charges are closely connected with those of pluviosity; the protectionist boom being always loudest after long periods of excessive rains in western Europe, accompanied by a deficiency of the same in the eastern section of our continent.

Slight Bronchial Dilatations in Small Children.—Hutinel describes small bronchial dilatations as not infrequent in children, although not so serious and intractable as in the adult. They are not often infected and fetid expectoration is rarely seen. They occur in hereditary syphilis, in tuberculosis rarely, after bronchopneumonia, measles, pertussis, and the aspiration of foreign bodies into the trachea. They are accompanied by a considerable amount of sclerosis and dilatation of the blood-vessels of the lung. They often begin insidiously with few symptoms, slight fever, almost no dyspnea, persistent cough, and little else. When they have a more acute course there are more marked fever, purulent expectoration, and moderate dyspnea, with a harassing cough, which recurs easily. The physical signs are moist, subcrepitant râles, large and small, gurgles, and rhonchi. The vesicular murmur is impaired, the voice and cough cavernous. If the sclerosis is not marked the cavities may disappear with the development of the lungs. Treatment in the acute attack consists of enveloping the chest in moist compresses. Later general tonic and hygienic treatment, respiratory gymnastics, and life in the open air are valuable remedies.—*La Presse Médicale.*

Chronological Relations of Ovulation and Menstruation.—H. Busquet in considering the chronological relation of ovulation and menstruation, cites the observations of Leopold and Kufferath, who examined the ovaries of women operated on during menstruation, and during the intermenstrual period, with reference to the presence of the corpus luteum. They found that the menstruation occurred at the moment of maturity and rupture of the ovisac. Pouchet has published a case of unique coitus in which the act occurred fifteen days after menstruation and fecundation occurred. Fraenkel was of opinion that one of the results of the internal secretion of the corpus luteum was to cause menstruation. In nine cases of laparotomy with healthy ovaries he cauterized the corpus luteum and prevented the next menstruation. Villemin found that the cycle occurs thus: the Graafian follicle ruptures midway between the menstrual periods; twelve to fifteen days afterward the corpus luteum is present and menstruation occurs. Conclusions are that menstruation is a hemorrhage caused by the corpus luteum fourteen to fifteen days after ovulation. This question could be decided if surgeons would systematically examine the follicles of all women on whom laparotomy is done, in connection with the date of the last menstruation.—*La Presse Médicale.*

Congenital Malaria.—Pietro Sabella discusses the possibility of the communication of malaria to the infant by way of the placenta, a subject on which a variety of opinions have been expressed. It has been demonstrated that in many infectious diseases the microorganisms pass from mother to child by the placenta. But communication by the placenta has not been demonstrated for the schizomycetes and some forms of protozoa. The opinion that malaria may be congenital has been expressed by many authors and founded on many cases. Could we find a case in which the parasite of malaria was found in the blood of a new-born child at the same time that it was present in that of the mother the transmissibility would be proven. But no such case has been recorded up to the present date. The author gives the histories of two cases in which malarial parasites were present in the blood of the mother, in both of which abortion occurred. The blood of the fetus in each case was examined and no malarial parasites found on the fetal side of the placenta.—*Il Policlinico.*

MEDICAL RECORD.

A Weekly Journal of Medicine and Surgery.

New York, August 5, 1911.

HOSPITALS IN GREAT BRITAIN AND THE PROPOSED NATIONAL INSURANCE BILL.

UNDOUBTEDLY if Mr. Lloyd George's bill for the insurance of the working classes of Great Britain becomes law, and this now seems the probable outcome of the situation, the effect on medical practice will be revolutionary. Especially its influence for good or evil, as the case may be, will be felt on hospitals. The most striking feature of the recently published British Parliamentary Committee's report dealing with the matter is that part which foreshadows the future of the hospitals as affected by the bill. Of course, the conclusions of the report are to a large extent guesswork, but these appear to be founded on fairly sound premises and are the expression of opinion on the part of men qualified to speak with authority. At any rate, the predictions of the committee as to what may happen have the merit of probability, and as such will commend themselves to the consideration of the general public.

With respect to educational administration the committee is of the opinion that, should the bill pass into law, its effect will be to revolutionize completely the conditions of medical treatment and relief which now exist among the entire elementary school population. Organization will take the place of hap-hazard methods, and the wage-earning classes will be brought into universal and direct contact with medical practitioners. The main point, however, is that the British hospital system as a whole will be profoundly affected; indeed, shaken at its base. The committee holds the views that voluntary funds, the Hospital Saturday Fund for instance, will cease. Admittance to hospitals in Great Britain is free and most of them are maintained chiefly by charity; therefore the conjecture is advanced by the committee that the need for charitable relief for the working population will no longer exist. Outpatients' departments will have no *raison d' êtrc.* and will, therefore, disappear, and in the words of the report "inpatient institutions and hospitals must eventually come under the supervision or control of the local Health Councils." If these prophetic utterances by the sages of the Parliamentary Committee should come to pass, the result may be quite dissimilar to that which some of the ardent supporters of the bill imagine it will be. The benefits that appear likely to accrue to the community at large from the passage of the bill are that outpatients' department of hospitals will be free to undertake the service of affording medical relief to school children, while the serious objections which have been brought against the subsidizing of charitable institutions which are not under official supervision or control will vanish. The present system of voluntary contributions to hospitals will pass into oblivion and, according to report, "will practically throw much of such hospital provision open to new arrangements and make support from public funds necessary." In short, it seems that all relating to medical and surgical care will ultimately come under state or public control. Not only will the hospital system be revolutionized, but the momentous event will be merely incidental to the revolutionizing of the medical profession. It will become to all intents and purposes, a branch of the civil service and its members will be servants of the state and of the people. Whatever may be the effect of the bill as regards the population at large, in the opinion of those best able to judge, it will not conduce to the dignity, efficiency, or prosperity of the medical profession. Less scope, by far, will be given to individuality, and whenever this happens efficiency is necessarily lowered.

That the bill has grave defects is obvious to all, from the very fact that the medical profession of Great Britain, with a most remarkable unanimity, is opposed to it. Medical men are not generally regarded as selfish, so that it is not for selfish reasons alone that the whole trend of medical opinion in Great Britain is antagonistic to the bill as it now stands. A most reasonable appeal has been made to the British Chancellor of the Exchequer, that before so important a measure is made law its provisions should be subjected to careful and minute scrutiny, and that it should be discussed from every standpoint. The bill is of international interest, and particularly so to members of the medical profession. Great Britain is leading the way in a great social revolution which must of necessity be a matter of concern to other nations.

ANAPHYLAXIS.

SINCE the development of serum therapy, it has been observed that occasionally serious and even fatal results follow the employment of antitoxic serums. An explanation of many of such cases is found in the phenomena of anaphylaxis, a term first employed by Richet, and which literally means something antagonistic to the protection of the individual. Richet gave some animals a non-lethal dose of actinocongestin, a protein derived from the starfish. After a definite interval of time had elapsed the animal received a second injection of an even smaller amount, which was followed by grave symptoms and often death. This phenomenon was diagnosed anaphylaxis. This result could not be due to cumulative action, since both doses were non-lethal. The preliminary dose is termed the sensitizing, the second the intoxicating injection. The period of incubation is the time that must elapse before the intoxicating dose will provoke the

characteristic symptoms. This period ranges from eight to fifteen days, after which the animal is sensitized or hypersensitive.

In an article appearing in the *Medical Chronicle* for May, 1911, Mr. R. Donaldson presents an exhaustive review of anaphylaxis in which he discusses the various facts known and theories still unproven. The number of persons who exhibit intolerance is estimated at about 20 per cent. Of all persons inoculated such results may follow both primary inoculation and reinoculation, but are considerably more frequent after reinoculation, constituting 80 per cent. or so of all serious accidents. Further, such accidents in man may be subdivided into those followed by more or less local reaction, and those which present all the phenomena of complete anaphylactic shock. Local symptoms are usually slight, the most frequent lesion is an urticaria short or prolonged. In some cases, however, the injection may be followed quickly by a simultaneous general urticaria with edema and cyanosis of the face, the respirations resemble those in a very severe attack of asthma; the heart's action becomes weak and the patient is in a state of collapse; rigors and convulsions may occur or the patient may become comatose. Intolerance of or undue susceptibility to the action of serum has been mostly observed after the use of antidiphtheritic serum, and it was found that the symptoms were not due to the antitoxin but to the horse serum containing it.

The discussion by the author on the relationship of anaphylaxis to certain diseases, although suggestive, is far too long to be more than briefly referred to here. Pellagra has been stated recently to be an anaphylactic lesion, and according to Moschowitz nearly all the various manifestations of the "exudative" diathesis occur in neurotic individuals. This diathesis includes hay fever, urtcaria, mucous colitis, eczema, and other skin lesions. But all the above, as the same investigator points out, occur in susceptible individuals, persons who have somehow become sensitized. Exophthalmic goiter, migraine, epilepsy, tetany, and eclampsia have been included among the anaphylactic diseases. Von Pirquet regards the local and general reactions following the administration of tuberculin as anaphylactic in character. All the diseases which are associated with anaphylactic reaction have been shown by Moschowitz to possess one factor in common, an eosinophilia, and he declares that eosinophilia, like the neurotic diathesis, is frequently inherited. He concludes by stating that in view of the fact that diverse manifestations of anaphylaxis are associated with a persistent eosinophilia, it may be found that a susceptibility to anaphylaxis is present only in those with an acquired or congenital eosinophilia. In his opinion the eosinophil cells may both sensitize and excite the anaphylactic symptoms.

In consequence of certain individuals becoming anaphylactized or exhibiting extreme sensitiveness to the injection of some serums, many physicians are averse to using diphtheria antitoxin, for instance, as a prophylactic. They argue that a person, even if he be not subject to asthma, may be specially susceptible to the serum, and if he be not naturally susceptible injection of the serum may render him artificially so. The question then arises whether it is justifiable or rather advisable to give antitoxin to persons who are only suspected to be suffering from diphtheria. Of course, in a few cases the delay may be injuriously prejudicial to the chances for recovery, but in the majority of cases the doubtful ones are not severe, and little risk will be run if the use of antitoxin be delayed for a day or two when a correct diagnosis can be made. In children under ten when the larynx is affected and in the absence of exudation of the fauces, if the disease is diphtheria the diagnosis is frequently difficult and outcome serious, therefore in such cases the safest course is to employ antitoxin, otherwise in doubtful cases a prophylactic injection is condemned by many as unnecessary and attended with some danger. Methods to diminish the anaphylactic toxicity of some serums without modifying the antitoxic action have been tried, but with little success.

THE CHRISTIAN SCIENTIST'S CRUELTY TO CHILDREN.

No one possessed of an open mind and a reasonable trend of thought would go so far as to assert that the practice of Christian Science as a healing agency is never of any avail. The influence of the mind over the body, of course, is very great and in certain affections, to which the adherents of this cult are very prone, Christian Science and allied modes of treatment have at times a remarkable recuperative effect. Unfortunately the leaders of the sect will not admit the patent fact of its limitations, but profess to believe that all and every kind of organic as well as functional ill can be cured by their denials of facts.

Henry Dwight Chapin, writing in the *Independent* of June 29, points out this evil and exemplifies it by the child. The complaints which are amenable to treatment by mental suggestion and the like are essentially affections of civilization due chiefly to the stress and strain of modern existence. For such as these the influence of the mind is ofttimes a panacea. But the mind of a child is not fully enough developed to exercise an intelligent influence over its own body; nor is the child competent to will and to determine its own course of action. If an adult in full possession of his senses elects to be treated for an organic disease by a Christian Scientist, the matter is mainly his own concern, except as regards infectious diseases. But in the case of a child the question is altogether different and it is not fair to the child that his life should be endangered.

The followers of Mother Eddy when shown the absurdity of their therapeutic pretensions turn the subject: "Ah!" say they, "but it gives us such rest and peace." To this says Chapin: "A peace derived by ignoring the sterner facts of life is too dearly bought. Against the vapid joy and peace that this form of faith gives to any neurotic man or woman you may often count a sick or maimed or dying child. This is the dark, cruel, sinister side of the picture. It is really the child that is offered

as a sacrifice on the altar of this unnatural belief." The author is of the opinion that this age is too tolerant and he thinks it is time for plain and emphatic words. He says that an appeal should be made not only to the intelligence, but to the public heart and conscience by those who can speak with knowledge and authority.
